WELLCOME
HISTORICAL
MEDICAL
LIBRARY

TO

WILLIAM SAUNDERS, M.D. F.R.S.

FELLOW OF THE ROYAL COLLEGE OF PHYSICIANS, AND OF THE
ANTIQUARIAN AND OTHER SOCIETIES;

AUTHOR OF
TREATISES ON THE LIVER AND ON MINERAL WATERS,
AND MANY YEARS AN HONOURABLE, LIBERAL, AND
SUCCESSFUL PRACTITIONER IN LONDON;

THIS WORK

WAS DEDICATED,

AS

A MARK OF RESPECT AND ESTEEM,

BY

HIS SINCERE FRIEND,

THE AUTHOR.

PREFACE.

The principal additions and improvements in the present edition of the Medical Dictionary, are in the introduction of the terms of Botany and those of Mineralogy, and the most modern discoveries in Chemistry and Physiology. The work, therefore, will now be found to contain an account of every article connected with the study of medicine.

In conducting this laborious undertaking, particular attention has been given to

1. The accentuation, in order that the proper pronunciation of the words may be obtained.

2. The derivation of the terms, and the declension of the words in common use.

3. The definitions, which are from the most approved sources.

4. The introduction of all the modern discoveries in the several branches of medical science.

In the selection and arrangement of the most compendious, the most clear, and the most perfect account of the several articles of Anatomy, Biography, Botany, Chemistry, the Materia Medica, Midwifery, Mineralogy, Pathology, Pharmacy, and Physiology; the Compiler has again to acknowledge his obligations to Abernethy, Accum, Aikin, Albinus, Bell, Brande, Bergius, Blanchard, Burns, Burserius, Callisen, Casselli, Cooper, Cruickshank, Cullen, Davy, Denman, Duncan, the Editors of the London and Edinburgh Dispensaries, and of Rees' Cyclopædia, and Motherby's Medical Dictionary, Fourcroy, Good, Haller, Henry, Hoffman, Innis, Latta, Larcy, Lavoisier, Lewis, Linnæus, Magendie, Meyer, Murray, Nicholson, Orfila, Pott, Richerand, Richter, Saunders, Sauvage, Scarpa, Smith, Sœmmering, Swediaur, Symonds, Thomas, Thompson, Turton, Ure, (from whose condensed and comprehensive work on chemistry large extracts have been made,) Vaughan, Vossius, Willan, Woodville, &c. &c.

It was his original intention to have given to each writer the merit of the particular description selected from his work, but having occasion to consult, frequently to abridge, and sometimes to alter various passages; and finding it difficult, and in many instances impossible, to discover the original writer of several articles; and convinced at the same time it would be attended with no particular advantage, he has preferred making a general acknowledgment to particularizing the labours of each individual. If he has been so fortunate as to have compressed within the narrow limits of the present publication much general and useful information, his object will be fully answered.

Saville-Row, *September*, 1825.

A NEW

MEDICAL DICTIONARY.

A. 1. In composition this letter, the *α* in Greek, and *a* in Latin, signifies *without:* thus *aphonia*, without voice, *acaulis*, without stem, *aphyllus*, without a leaf, &c.

2. A. AA. (From *ανα*, which signifies of each.) Abbreviations of *ana*, which word is used in prescriptions after the mention of two or more ingredients, when it implies, that the quantity mentioned of each ingredient should be taken; thus, ℞. *Potassæ nitratis—Sacchari albi* āā ʒj. Take nitrate of potassa and white sugar, of each one drachm.

A′ABAM. An obsolete term used by some ancient alchemists for lead.

AA′RON. A physician of Alexandria, author of thirty books in the Syriac tongue, containing the whole practice of physic, chiefly collected from the Greek writings, and supposed to have been written before A. D. 620. He first mentioned, and described the small-pox and measles, which were probably brought thither by the Arabians. He directed the vein under the tongue to be opened in jaundice, and noticed the white colour of the fæces in that disease. His works are lost, except some fragments, preserved by Rhazes.

AA′VORA. The fruit of a species of palm-tree, which grows in the West Indies and Africa. It is of the size of a hen's egg, and included with several more in a large shell. In the middle of the fruit there is a hard nut, about the size of a peach-stone, which contains a white almond, very astringent, and useful against a diarrhœa.

ABA′CTUS. *Abigeatus.* Among the ancient physicians, this term was used for a miscarriage, procured by art, or force of medicines, in contradistinction to *abortus*, which meant a natural miscarriage.

A′BACUS. (From an Hebrew word, signifying dust.) A table for preparations, so called from the usage of mathematicians of drawing their figures upon tables sprinkled with dust.

ABAI′SIR. *Abasis.* Ivory black; and also calcareous powder.

ABALIENA′TIO. Abalienation; or a decay of the body, or mind.

ABALIENA′TUS. 1. Corrupted.

2. A part so destroyed as to require immediate extirpation.

3. The total destruction of the senses, whether external or internal, by disease.

A′BANET. (Hebrew. The girdle worn by the Jewish priests.) A girdle-like bandage.

ABAPTI′STA. (From *α*, priv. and *βαπτω*, to plunge.) *Abaptiston.* 1. The shoulders of the old trepan.

2. This term is employed by Galen, Fabricius ab Aquapendente, Scultetus, and others, to denote the conical saw with a circular edge, (otherwise called modiolus, or terebra,) which was formerly used by surgeons to perforate the cranium.

ABAPTI′STON. See *Abaptista.*

ABARNAHAS. A chemical term formerly used in the transmutation of metals, signifying *luna plena, magnes*, or *magnesia.*

ABA′RTAMEN. Lead.

ABARTICULATION. (From *ab*, and *articulus*, a joint.) A species of articulation which has evident motion. See *Diarthrosis.*

A′BAS. An Arabian term for the scald-head, and also for epilepsy.

ABA′SIS. See *Abaisir.*

ABBREVIATION. The principal uses of medicinal abbreviations are in prescriptions, in which they are certain marks, or half words, used by physicians for despatch and conveniency when they prescribe; thus:—℞ readily supplies the place of *recipe—h. s.* that of *hora somni—n. m.* that of *nux moschata—elect.* that of *electarium*, &c.; and in general all the names of compound medicines, with the several ingredients, are frequently wrote only up to their first or second syllable, or sometimes to their third or fourth, to make them clear and expressive. Thus *Croc. Anglic.* stands for *Crocus Anglicanus—Conf. Aromat.* for *Confectio Aromatica*, &c. A point being always placed at the end of such syllable, shows the word to be incomplete.

ABBREVIATUS. Abbreviate; shortened. A term often used in botany.

ABDO′MEN. (*Abdomen, inis.* n.; from *abdo*, to hide: because it hides the viscera. It is also derived from *abdere*, to hide, and *omentum*, the caul; by others *omen* is said to be only a termination, as from *lego*, *legumen*, so from *abdo*, *abdomen*.) The belly. The largest cavity in the body, bounded superiorly by the diaphragm, by which it is separated from the chest; inferiorly by the bones of the pubes and ischium; on each side by various muscles, the short ribs, and ossa ilii; anteriorly by the abdominal muscles, and posteriorly by the vertebræ of the loins, the os sacrum and os coccygis. Internally it is invested by a smooth membrane, called peritoneum, and externally by muscles and common integuments.

In the cavity of the belly are contained,

Anteriorly and *laterally*,

1. The epiploon. 2. The stomach. 3. The large and small intestines. 4. The mesentery. 5. The lacteal vessels. 6. The pancreas. 7. The spleen. 8. The liver and gall-bladder.

Posteriorly, without the peritoneum,

1. The kidneys. 2. The supra-renal glands. 3. The ureters. 4. The receptaculum chyli. 5. The descending aorta. 6. The ascending vena cava.

Inferiorly in the pelvis, and *without the peritoneum*.

In men, 1. The urinary bladder. 2. The spermatic vessels. 3. The rectum.

In women, besides the urinary bladder and intestinum rectum, there are,

1. The uterus. 2. The four ligaments of the uterus. 3. The two ovaria. 4. The two Fallopian tubes. 5. The vagina.

The fore part of this cavity, as has been mentioned, is covered with muscles and common integuments, in the middle of which is the navel. It is this part of the body which is properly called abdomen; it is distinguished, by anatomists, into regions. See *Body*.

The posterior part of the abdomen is called the loins, and the sides the flanks.

ABDOMINALIS. (From *abdomen*, the belly.) Abdominal; pertaining to the belly.

Abdominal hernia. See *Hernia*.

Abdominal muscles. See *Muscles*.

Abdominal regions. See *Body*.

Abdominal ring. See *Annulus abdominis*.

ABDU'CENS. See *Abducent*.

ABDUCENS LABIORUM. See *Levator anguli oris*.

ABDUCENT. (*Abducens*; from *ab*, from, and *ducere*, to draw.) The name of some muscles which draw parts back in the opposite direction to others. See *Abductor*.

Abducent muscles. See *Abductor*.

Abducent nerves. See *Nervi abducentes*.

ABDUC'TOR. (From *abduco*, to draw away.) *Abducens*. A muscle, the office of which is to pull back or draw the member to which it is affixed from some other. The antagonist is called *adductor*.

ABDUCTOR AURICULARIS. See *Posterior auris*.

ABDUCTOR AURIS. See *Posterior auris*.

ABDUCTOR BREVIS ALTER. See *Abductor pollicis manus*.

ABDUCTOR INDICIS MANUS. An internal interosseous muscle of the fore-finger, situated on the hand. *Abductor* of Douglas; *Semi-interosseus indicis* of Winslow; *Abductor indicis* of Cowper. It arises from the superior part of the metacarpal bone, and the os trapezium, on its inside, by a fleshy beginning, runs towards the metacarpal bone of the fore-finger, adheres to it, and is connected by a broad tendon to the superior part of the first phalanx of the fore-finger. Sometimes it arises by a double tendon. Its use is to draw the fore-finger from the rest, towards the thumb, and to bend it somewhat towards the palm.

ABDUCTOR INDICIS PEDIS. An internal interosseous muscle of the fore-toe, which arises tendinous and fleshy, by two origins, from the root of the inside of the metatarsal bone of the fore-toe, from the outside of the root of the metatarsal bone of the great-toe, and from the os cuneiforme internum, and is inserted tendinous into the inside of the root of the first joint of the fore-toe. Its use is to pull the fore-toe inwards, from the rest of the small toes.

ABDUCTOR LONGUS POLLICIS MANUS. See *Extensor ossis metacarpi pollicis manûs*.

ABDUCTOR MEDII DIGITI PEDIS. An interosseous muscle of the foot, which arises tendinous and fleshy, from the inside of the root of the metatarsal bone of the middle toe internally, and is inserted tendinous into the inside of the root of the first joint of the middle toe. Its use is to pull the middle toe inwards.

ABDUCTOR MINIMI DIGITI MANUS. A muscle of the little finger, situated on the hand. *Carpo-phalangien du petit doigt* of Dumas; *Extensor tertii internodii minimi digiti* of Douglas; *Hypothenar minor* of Winslow. It arises fleshy from the pisiform bone, and from that part of the *ligamentum carpi annulare* next it, and is inserted, tendinous, into the inner side of the upper end of the first bone of the little finger. Its use is to draw the little finger from the rest.

ABDUCTOR MINIMI DIGITI PEDIS. A muscle of the little toe. *Calcaneo-phalangien du petit doigt* of Dumas; *Adductor* of Douglas; *Parathenar major* of Winslow, by whom this muscle is divided into two, *Parathenar major* and *metatarseus*; *Adductor minimi digiti* of Cowper. It arises tendinous and fleshy, from the semicircular edge of a cavity on the inferior part of the protuberance of the os calcis, and from the rest of the metatarsal bone of the little toe, and is inserted into the root of the first joint of the little toe externally. Its use is to bend the little toe, and its metatarsal bone, downwards, and to draw the little toe from the rest.

ABDUCTOR OCULI. See *Rectus externus oculi*.

ABDUCTOR POLLICIS MANUS. A muscle of the thumb, situated on the hand. *Scaphosus-phalangien du pouce* of Dumas; *Adductor pollicis manus*, and *Adductor brevis alter* of Albinus; *Adductor thenar Riolani* of Douglas, (the *adductor brevis alter* of Albinus is the inner portion of this muscle;) *Adductor pollicis* of Cowper. It arises by a broad tendinous and fleshy beginning, from the *ligamentum carpi annulare*, and from the *os trapezium*, and is inserted tendinous into the outer side of the root of the first bone of the thumb. Its use is to draw the thumb from the fingers.

ABDUCTOR POLLICIS PEDIS. A muscle of the great toe, situated on the foot. *Calcaneo-phalangien du pouce* of Dumas. *Abductor* of Douglas. *Thenar* of Winslow. *Abductor pollicis* of Cowper. It arises fleshy, from the inside of the root of the protuberance of the os calcis, where it forms the heel, and tendinous from the same bone, where it joins the os naviculare; and is inserted tendinous into the internal sesamoid bone and root of the first joint of the great toe. Its use is to pull the great toe from the rest.

ABDUCTOR TERTII DIGITI PEDIS. An interosseous muscle of the foot, that arises tendinous and fleshy from the inside and the inferior part of the root of the metatarsal bone of the third toe; and is inserted tendinous into the inside of the root of the first joint of the third toe. Its use is to pull the third toe inwards.

Abebæ′os. (From *α*, neg. and *βεβαιος*, firm.) *Abebæus*. Weak, infirm, unsteady. A term made use of by Hippocrates, de Signis.

Abebæ′us. See *Abebæos*.

ABELMO′SCHUS. (An Arabian word.) See *Hibiscus Abelmoschus*.

Abelmosch. See *Hibiscus Abelmoschus*.

Abelmusk. See *Hibiscus Abelmoschus*.

ABERRA′TIO (From *ab* and *erro*, to wander from.) Formerly applied to some deviations from what was natural, as a dislocation, and monstrosities.

Abe′ssi. (An Arabian term which means filth.) The alvine excrements.

A′besum. Quicklime.

Abevacua′tio. (From *ab*, dim. and *evacuo*, to pour out.) A partial or incomplete evacuation of the peccant humours, either naturally or by art.

Abicum. The thyroid cartilage.

A′BIES. (*Abies, etis*. fem.; from *abeo*, to proceed, because it rises to a great height; or from *απιος*, a wild pear, the fruit of which its cones something resemble.) The fir. See *Pinus*.

Abies Canadensis. See *Pinus Balsamea*.

Abigea′tus. See *Abactus*.

ABIO′TOS. (From *α*, neg. and *βιοω*, to live.) Deadly. A name given to hemlock, from its deadly qualities. See *Conium maculatum*.

ABLACTA′TIO. (From *ab*, from, and *lac*, milk.) Ablactation, or the weaning of a child from the breast.

ABLATION. (*Ablatio*; from *aufero*, to take away.) 1. The taking away from the body whatever is hurtful. A term that is seldom used but in its general sense, to clothing, diet, exercise, &c. In some old writings, it expresses the interval betwixt two fits of a fever, or the time of remission.

2. Formerly chemists employed this term to signify the removal of any thing that is either finished or else no longer necessary in a process.

ABLUE′NT. (*Abluens*; from *abluo*, to wash away.) Abstergent. Medicines which were formerly supposed to purify or cleanse the blood.

ABLUTION. (*Ablutio*; from *abluo*, to wash off.) 1. A washing or cleansing either of the body or the intestines.

2. In chemistry it signifies the purifying of a body, by repeated effusions of a proper liquor.

Abo′it. An Arabic term for white lead.

Aboli′tio. (From *aboleo*, to destroy.) The separation or destruction of diseased parts.

Aborsus. A miscarriage.

ABORTIENS. Miscarrying.

In botany, it is sometimes used synonymously with *sterilis*, sterile or barren.

ABORTION. (*Abortio*; from *aborior*, to be sterile.) *Aborsus*; *Amblosis*; *Diaphthora*; *Ectrosis*; *Exambloma*; *Examblosis*; *Apopallesis*; *Apopalsis*; *Apophthora*. Miscarriage, or the expulsion of the fœtus from the uterus, before the seventh month, after which it is called premature labour. It most commonly occurs between the eighth and eleventh weeks of pregnancy, but may happen at a later period. In early gestation, the ovum sometimes comes off entire; sometimes the fœtus is first expelled, and the placenta afterwards. It is preceded by floodings, pains in the back, loins, and lower part of the abdomen, evacuation of the water, shiverings, palpitation of the heart, nausea, anxiety, syncope, subsiding of the breasts and belly, pain in the inside of the thighs, opening and moisture of the os tincæ. The principal causes of miscarriage are blows or falls; great exertion or fatigue; sudden frights and other violent emotions of the mind; a diet too sparing or too nutritious; the abuse of spirituous liquors; other diseases, particularly fevers, and hæmorrhages; likewise excessive bleeding, profuse diarrhœa or colic, particularly from accumulated fæces; immoderate venery, &c. The spontaneous vomiting so common in pregnancy, rarely occasions this accident: but when induced and kept up by drastic medicines, it may be very likely to have that effect. Abortion often happens without any obvious cause, from some defect in the uterus, or in the fœtus itself, which we cannot satisfactorily explain. Hence it will take place repeatedly in the same female at a particular period of pregnancy; perhaps in some measure from the influence of habit.

The treatment of abortion must vary considerably according to the constitution of the patient, and the causes giving rise to it. If the incipient symptoms should appear in a female of a plethoric habit, it may be proper to take a moderate quantity of blood from the arm, then clear the bowels by some mild cathartic, as the sulphas magnesiæ in the infusum rosæ, afterwards exhibiting small doses of nitrate of potash, directing the patient to remain quiet in a recumbent position, kept as cool as possible, with a low diet, and the antiphlogistic regimen in other respects. Should there be much flooding, cloths wetted with cold water ought to be applied to the region of the uterus, or even introduced into the vagina, to obstruct the escape of the blood mechanically. Where violent forcing pains attend, opium should be given by the mouth or in the form of glyster, after premising proper evacuations. Should these means not avail to check the discharge of the forcing pains, and particularly if the water be evacuated, there can be no expectation of preventing the miscarriage; and where there is reason for believing the fœtus dead, from the breasts having previously subsided, the morning sickness gone off, the motion stopped, &c. it will be proper rather to encourage it by manual assistance.

If on the other hand females of a delicate and irritable habit, rather deficient in blood, be subject to abortion, or where this accident is threatened by profuse evacuations and other debilitating causes, it may be more probably prevented by a diet nutritious, yet easy of digestion, with tonic medicines, and the use of the cold bath, attending at the same time to the state of the bowels, giving opium if pain attend, and carefully avoiding the several exciting causes.

ABORTIVE. (*Abortivus*; from *aborior*, to be sterile.) That which is capable of occasioning an abortion, or miscarriage, in pregnant women. It is now generally believed, that the medicines which produce a miscarriage, effect it by their violent operation on the system, and not by any specific action on the womb.

ABORTUS. A miscarriage.

Abra′sa. (From *abrado*, to shave off.) Ulcers attended with abrasion.

ABRASION. (*Abrasio*; from *abrado*, to tear off.) This word is generally employed to signify the destruction of the natural mucus of any part, as the stomach, intestines, urinary bladder, &c. It is also applied to any part slightly torn away by attrition, as the skin, &c.

A′brathan. Corrupted from abrotanum, southernwood. See *Artemisia abrotanum*.

A′brette. See *Hibiscus Abelmoschus*.

A′bric. An Arabic term for sulphur.

Abro′ma. (From *α*, neg. and *βρωμα*, food; *i. e.* not fit to be eaten.) A tree of New South Wales, which yields a gum.

ABRO′TANUM. (*Αβροτανον*; from *α*, neg.

and *βροτος*, mortal; because it never decays: or from *αβρος*, soft, and *τονος*, extension; from the delicacy of its texture.) Common southernwood. See *Artemisia.*

ABROTANUM MAS. See *Artemisia.*

ABROTONI'TES. (From *abrotanum.*) A wine mentioned by Dioscorides, impregnated with *abrotanum*, or southernwood, in the proportion of about one hundred ounces of the dried leaves, to about seven gallons of must.

ABRUPTE'. Abruptly. Applied to pinnate leaves which terminate without an odd leaf or lobe;—*folia abruptè pinnata.*

ABSCEDE'NTIA. (From *abscedo*, to separate.) Decayed parts of the body, which, in a morbid state, are separated from the sound.

ABSCESS. (*Abscessus;* from *abscedo*, to depart: because parts, which were before contiguous, become separated, or depart from each other.) *Abscessio; Imposthuma.* A collection of pus in the cellular membrane, or in the viscera, or in bones, preceded by inflammation. Abscesses are variously denominated according to their seat: as empyema, when in the cavity of the pleura; vomica, in the lungs; panaris, in any of the fingers; hypopyon, in the anterior chamber of the eye; arthropuosis, in a joint; lumbar abscess, &c.

The formation of an abscess is the result of inflammation terminating in suppuration. This is known by a throbbing pain, which lessens by degrees, as well as the heat, tension, and redness of the inflamed part; and if the pus be near the surface, a cream-like whiteness is soon perceived, with a prominence about the middle, or at the inferior part, then a fluctuation may be felt, which becomes gradually more distinct, till at length the matter makes its way externally. When suppuration occurs to a considerable extent, or in a part of importance to life, there are usually rigors, or sudden attacks of chilliness, followed by flushes of heat; and unless the matter be soon discharged, and the abscess healed, hectic fever generally comes on. When abscesses form in the cellular membrane in persons of a tolerably good constitution, they are usually circumscribed, in consequence of coagulable lymph having been previously effused, and having obliterated the communication with the adjoining cells; but in those of a weakly, and especially a scrophulous constitution, from this not occurring, the pus is very apt to diffuse itself, like the water in anasarca. Another circumstance, which may prevent its readily reaching the surface, is its collecting under an aponeurosis, or other part of dense structure, when the process of ulceration will rather extend in another direction; thus pus accumulating in the loins, may descend to the lower part of the thigh.

When suppuration occurs, if the inflammation have not yet subsided, it may be necessary to employ means calculated to moderate this, in order to limit the extent of the abscess: but evacuations must not be carried too far, or there will not be power in the system to heal it afterwards. If the disease be near the surface, fomentations or warm emollient poultices should be employed, to take off the tension of the skin, and promote the process of ulceration in that direction. As soon as fluctuation is obvious, it will be generally proper to make an opening, lest contiguous parts of importance should be injured; and often at an earlier period, where the matter is prevented from reaching the surface by a fascia, &c. but it is sometimes advisable to wait awhile, especially in large spontaneous abscesses, where the constitution is much debilitated, till by the use of a nutritious diet, with bark and other tonic means, this can be somewhat improved. There are different modes of opening abscesses. 1. By incision or puncture; this is generally the best, as being least painful, and most expeditious, and the extent of the aperture can be better regulated. 2. By caustic; this may be sometimes preferable when suppuration goes on very slowly in glandular parts, (especially in scrophulous and venereal cases,) lessening the subjacent tumour, giving free vent to the matter, and exciting more healthy action in the sore; but it sometimes causes much deformity, it can hardly reach deep seated abscesses, and the delay may be often dangerous. 3. By seton; this is sometimes advantageous in superficial abscesses, (where suppuration is likely to continue,) about the neck and face, leaving generally but a small scar; likewise when near joints, or other important parts liable to be injured by the scalpel or caustic. See *Lumbar Abscess*, and *Ulcer.*

ABSCES'SUS. See *Abscess.*

ABSCISSION. (*Abscissio;* from *ab*, and *scindo*, to cut.) 1. The cutting away some morbid, or other part, by an edged instrument. The abscission of the prepuce makes what we call circumcision.

2. Abscission is sometimes used by medical writers to denote the sudden termination of a disease in death, before it arrives at its decline.

3. Celsus frequently uses the term *abscissa vox* to express a loss of voice.

ABSINTHITES. Absinthiac, or absinthiated. Something tinged or impregnated with the virtues of absinthium or wormwood.

ABSI'NTHIUM. (*Absinthium, thii.* n. *αψινθιον*; from *α*, neg. and *ψινθος*, pleasant: so called from the disagreeableness of the taste.) Wormwood. See *Artemisia.*

ABSINTHIUM COMMUNE. Common Wormwood. See *Artemisia Absinthium.*

ABSINTHIUM MARITIMUM. Sea Wormwood. See *Artemisia Maritima.*

ABSINTHIUM PONTICUM. Roman Wormwood. See *Artemisia Pontica.*

ABSINTHIUM VULGARE. Common Wormwood. See *Artemisia Absinthium.*

ABSORBENS. See *Absorbent.*

ABSORBENT. (*Absorbens;* from *absorbeo*, to suck up.) 1. The small, delicate, transparent vessels, which take up substances from the surface of the body, or from any cavity, and carry it to the blood, are termed absorbents or absorbing vessels. They are denominated, according to the liquids which they convey, lacteals and lymphatics. See *Lacteal* and *Lymphatic.*

2. Those medicines are so termed, which have no acrimony in themselves, and destroy acidities in the stomach and bowels; such are magnesia, prepared chalk, oyster-shells, crab's claws, &c.

3. Substances are also so called by chemists which have the faculty of withdrawing moisture from the atmosphere.

Absorbing vessels. See *Absorbent.*

ABSORPTION. (*Absorptio;* from *absorbeo*, to suck up.) 1. A function in an animated body, arranged by physiologists under the head of natural actions. It signifies the taking up of substances applied to the mouths of absorbing vessels; thus the nutritious part of the food is absorbed from the intestinal canal by the lacteals; thus mercury is taken into the system by the lymphatics of the skin, &c. The principle by which this function takes place, is a power inherent in the mouths of the absorbents, a *vis insita*, dependent on the degree of irritability of their internal membrane by which they contract and propel their contents forwards.

2. By this term chemists understand the conversion of a gaseous fluid into a liquid or solid, on being united with some other substance. It differs from condensation in this being the effect of mechanical pressure.

ABSTEMIOUS. (*Abstemius*; from *abs*, from, and *temetum*, wine.) Refraining absolutely from all use of wine; but the term is applied to a temperate mode of living, with respect to food generally.

Abste′ntio. Cælius Aurelianus uses this word to express a suppression, or retention: thus, *abstentio stercorum*, a retention of the excrements, which he mentions as a symptom very frequent in a satyriasis. In a sense somewhat different, he uses the word *abstenta*, applying it to the pleura, where he seems to mean that the humour of the inflamed pleura is prevented, by the adjacent bones, from extending itself.

ABSTERGENT. (*Abstergens*; from *abstergo*, to cleanse away.) Any application that cleanses or clears away foulness. The term is seldom employed by modern writers.

ABSTRACTION. (From *abstraho*, to draw away.) A term employed by chemists in the process of humid distillation, to signify that the fluid body is again drawn off from the solid, which it had dissolved.

Abstracti′tius. (From *abstraho*, to draw away.) An obsolete term formerly applied to any native spirit, not produced by fermentation.

A′bsus. The Egyptian lotus.

Abvacua′tio. (From *abvacuo*, to empty.) A morbid discharge; a large evacuation of any fluid, as of blood from a plethoric person. A term used by some old writers.

Aca′ca. (Ακακος; from *α*, neg. and *κακος*, bad.) Formerly applied to those diseases which are rather troublesome than dangerous.

ACA′CIA. (*Acacia*, *æ*. f. *ακακια*; from *ακαζω*, to sharpen.) The name of a genus of plants in the Linnæan system. Class, *Polygamia*; Order, *Monœcia*. The Egyptian thorn.

Acacia catechu. This plant affords a drug, formerly supposed to be an earthy substance brought from Japan, and therefore called *terra Japonica*, or Japan earth; afterwards it appeared to be an extract prepared in India, it was supposed till lately, from the juice of the *Mimosa catechu*, by boiling the wood and evaporating the decoction by the heat of the sun. But the shrub is now ascertained to be an acacia, and is termed *Acacia catechu*. It grows in great abundance in the kingdom of Bahar, and catechu comes to us principally from Bengal and Bombay. It has received the following names: *Acachou*; *Faufel*; *Cætchu*; *Caschu*; *Catechu*; *Cadichu*; *Cashow*; *Caitchu*; *Castjoe*; *Cachu*; *Cate*; *Kaath*. The natives call it *Cutt*, the English who reside there *Cutch*. In its purest state, it is a dry pulverable substance, outwardly of a reddish colour, internally of a shining dark brown, tinged with a reddish hue; in the mouth it discovers considerable adstringency, succeeded by a sweetish mucilaginous taste. It may be advantageously employed for most purposes where an adstringent is indicated; and is particularly useful in alvine fluxes, where astringents are required. Besides this, it is employed also in uterine profluvia, in laxity and debility of the viscera in general; and it is an excellent topical adstringent, when suffered to dissolve leisurely in the mouth, for laxities and ulcerations of the gums, apththous ulcers in the mouth, and similar affections. This extract is the basis of several formulæ in our pharmacopœias, particularly of a tincture: but one of the best forms under which it can be exhibited, is that of a simple infusion in warm water with a proportion of cinnamon, for by this means it is at once freed of its impurities and improved by the addition of the aromatic.

Fourcroy says that catechu is prepared from the seeds of a kind of palm, called areca. Sir Humphrey Davy has analysed catechu, and from his examination it appears, that from Bombay is of uniform texture, red-brown colour, and specific gravity 1.39: that from Bengal is more friable and less consistent, of a chocolate colour externally, but internally chocolate streaked with red-brown, and specific gravity 1.28. The catechu from either place differs little in its properties. Its taste is astringent, leaving behind a sensation of sweetness. It is almost wholly soluble in water. Two hundred grains of picked catechu from Bombay afforded 109 grains of tannin, 66 extractive matter, 13 mucilage, 10 residuum, chiefly sand and calcareous earth. The same quantity from Bengal; tannin 97 grains, extractive matter 73, mucilage 16, residual matter, being sand, with a small quantity of calcareous and aluminous earths, 14. Of the latter, the darkest parts appeared to afford most tannin, the lightest most extractive matter. The Hindoos prefer the lightest coloured, which has probably most sweetness, to chew with the betel-nut.

Of all the astringent substances we know, catechu appears to contain the largest proportion of tannin; and Mr. Purkis found, that one pound was equivalent to seven or eight of oak bark for the purpose of tanning leather.

Acacia Germanica. German acacia.

1. The name of the German black-thorn or sloe-tree, the *Prunus spinosa* of Linnæus.

2. The name of the inspissated juice of the fruit, as made in Germany; which, as well as the tree, is there called also *Acacia nostras*. It is now fallen into disuse.

Acacia Indica. See *Tamarindus Indica*.

Acacia nostras. See *Acacia Germanica*.

Acacia vera. 1. The systematic name of the tree which affords gum-arabic, formerly supposed to be a *Mimosa*. *Acacia*:—*spinis stipularibus patentibus, foliis bipinnatis, partialibus extimis glandula interstinctis, spicis globosis pedunculatis*, of Wildenow. The Egyptian Thorn. This tree yields the true Acacia Gum, or Gum-Arabic, called also *Gummi acanthinum*; *Gummi thebaicum*; *Gummi scorpionis*; *Gumlamac*; *Gummi senega*, or *senica*, or *senegalense*.

Cairo and Alexandria were the principal marts for gum-arabic, till the Dutch introduced the gum from Senegal into Europe, about the beginning of the seventeenth century, and this source now supplies the greater part of the vast consumption of this article. The tree which yields the senegal gum, grows abundantly on the sands, along the whole of the Barbary coast, and particularly about the river Senegal. There are several species, some of which yield a red astringent juice, but others afford only a pure, nearly colourless, insipid gum, which is the great article of commerce. These trees are from eighteen to twenty feet high, with thorny branches. The gum makes its appearance about the middle of November, when the soil has been thoroughly saturated with periodical rains. The gummy juice is seen to ooze through the trunk and branches, and, in about a fortnight, it hardens into roundish drops, of a yellowish white, which are beautifully brilliant where they are broken off, and entirely so when held in the mouth for a short time, to dissolve the outer surface. No clefts are made, nor any artificial means used by the Moors, to solicit the flow of the gum. The lumps of gum-senegal are usually about the size of partridge eggs, and the harvest continues about six weeks. This gum is a very wholesome and nutritious food; thousands of the Moors supporting themselves entirely upon it during the time of harvest. About six ounces is sufficient to support a man for a day; and it is besides mixed with milk, animal broths, and other victuals.

The gum-arabic, or that which comes directly from Egypt and the Levant, only differs from the gum-senegal in being of a lighter colour, and in smaller lumps; and it is also somewhat more brittle. In other respects, they resemble each other perfectly.

Gum-arabic is neither soluble in spirit nor in oil; but, in twice its quantity of water, it dissolves into a mucilaginous fluid, of the consistence of a thick syrup, and in this state answers many useful pharmaceutical purposes, by rendering oily, resinous, and pinguious substances miscible with water. The glutinous quality of gum-arabic renders it preferable to other gums and mucilages as a demulcent in coughs, hoarsenesses, and other catarrhal affections. It is also very generally employed in ardor urinæ, diarrhœas, and calculous complaints.

2. The name *Acacia vera* has also been used to denote the expressed juice of the immature pods of the tree termed *Acacia veravel.* This inspissated juice is brought from Egypt in roundish masses, wrapped up in thin bladders. It is considered as a mild astringent medicine. The Egyptians give it, in spitting of blood, in the quantity of a drachm, dissolved in any convenient liquor, and repeat this dose occasionally. They likewise employ it in collyria, for strengthening the eyes, and in gargles, for quinsies. It is now seldom used as a medicine, being superseded by the use of catechu, or kino.

ACACIA VERAVEL. See *Acacia vera.*

ACACIA ZEYLONICA. See *Hæmatoxylon Campechianum.*

Acacia gum. See *Acacia vera.*

ACACOS. The thrush. See *Aphtha.*

ACA′LAI. (Arabian.) Common salt.

ACA′LCUM. Tin.

ACALYCINUS. (From *α*, priv. and *calyx*, a flower-cup.) Without a calyx.

ACALYCIS. (From *α*, priv. and *calyx*, a flower-cup.) Without a calyx or flower-cup. Applied to plants which have no calyx.

ACA′MATOS. (From *α*, neg. and *καμνω*, to grow weary.) A perfect rest of the muscles, or that disposition of a limb which is equally distinct from flexion and extension.

ACA′NOR. (Hebrew.) A furnace.

ACA′NTHA. (*Ακανθα*; from *ακη*, a point.) 1. A thorn; or any thing pointed.

2. Sometimes applied to the spina dorsi.

ACANTHA′BOLUS. (From *ακανθα*; a thorn, and *βαλλω*, to cast out.) An instrument, or forceps, for taking out or removing thorns, or whatever may stick in the flesh.—*Paulus Ægineta.*

ACA′NTHE. The name of the artichoke in ancient authors.

ACA′NTHINUM. (From *ακανθα*, a thorn.) Gum-arabic was called *gummi acanthinum*, because it is produced from a thorny tree. See *Acacia Vera.*

ACANTICONE. See *Epidote.*

ACA′NTHULUS. (From *ακανθα*, a thorn.) A surgical instrument to draw out thorns or splinters, or to remove any extraneous matter from wounds.

ACA′NTHUS. (*Acanthus*, *i.* m. *ακανθος*; from *ακανθα*, a thorn: so named from being rough and prickly. The name of a genus of plants in the Linnæan system. Class, *Didynamia*; Order, *Angiospermia.* Bear's-breech.

ACANTHUS MOLLIS. The systematic name of the bear's-breech, or brank-ursine. *Acanthus*:—*foliis sinuatis inermibus*, of Linnæus, *Branca ursina* of the shops. The leaves and root abound with a mucilage, which is readily extracted by boiling or infusion. The roots are the most mucilaginous. Where this plant is common, it is employed for the same purposes to which althæa and other vegetables possessing similar qualities are applied among us. It is fallen into disuse. The herb-women too often sell the leaves of bear's-foot, and of cow's parsnip, for the bear's-breech.

ACA′PNON. (From *α*, priv. and *καπνος*, smoke.) 1. Common wild marjoram.

2. Unsmoked honey.

ACAROIS. The name of a genus of plants, from New South Wales.

ACAROIS RESINIFERA. The name of the tree which affords the Botany bay gum. See *Botany bay.*

A′CARUS. (From *ακαρης*, small.) The tick. An insect which breeds in the skin. A very numerous genus of minute insects which infest the skin of animals, and produce various complaints. Those which are found on the human body are

1. The *acarus domesticus*, or domestic tick.
2. The *acarus scabiei*, or itch tick.
3. The *acarus autumnalis*, or harvest-bug.

ACATALE′PSIA. (From *α*, neg. and *καταλαμβανω*, to apprehend.) Uncertainty in the prognosis or judgment of diseases.

ACA′TALIS. (From *α*, neg. and *χατεω*, to want.) The juniper tree: so named from the abundance of its seeds.

ACATA′POSIS. (From *α*, neg. and *καταπινω*, to swallow.) Difficult deglutition.

ACA′STATOS. (From *α*, neg. and *καθιστημι*, to determine.) Inconstant.

1. Fevers were so called which are anomalous in their appearance and irregular in their paroxysms.

2. Turbid urine without sediment.

ACAULIS. (From *α*, priv. and *caulis*, a stem.) Without stem. Plants destitute of stem are called *acaules*, stemless; as *Cypripedium acaule*, and *Carduus acaulis.* This term must not be too rigidly understood.

ACA′ZDIR. Tin.

ACCELERA′TOR. (From *accelero*, to hasten or propel.) The name of a muscle of the penis.

ACCELERATOR URINÆ. A muscle of the penis. *Ejaculator Seminis*; *Bulbo-syndesmo-caverneux* of Dumas; *Bulbo-cavernosus* of Winslow. It arises fleshy from the sphincter ani and membranous part of the urethra, and tendinous from the crus, near as far forwards as the beginning of the corpus cavernosum penis; the inferior fibres run more transversely, and the superior descend in an oblique direction. It is inserted into a line in the middle of the bulbous part of the urethra, where each joins with its fellow; by which the bulb is completely closed. The use of these muscles is to drive the urine or semen forward, and by grasping the bulbous part of the urethra, to push the blood towards its corpus cavernosum, and the glans, by which they are distended.

ACCESSION. (*Accessio*; from *accedo*, to approach. The commencement of a disease. A term mostly applied to a fever which has paroxysms or exacerbations: thus the accession of fever, means the commencement or approach of the febrile period.

ACCESSO′RIUS. (From *accedo*, to approach: so called from the course it takes.) Connected by contact or approach.

ACCESSORIUS LUMBALIS. A muscle of the loins. See *Sacro-lumbalis.*

ACCESSORIUS NERVUS. The name given by Willis to two nerves which ascend, one on each side, from the second, fourth, and fifth cervical pairs of nerves, through the great foramen of the occipital bone, and pass out again from the cranium through the foramina lacera, with the par vagum, to be distributed on the trapezius muscle.

A′CCIB. An obsolete term for lead.

ACCI′PITER. (From *accipio*, to take.)

1. The hawk: so named from its rapacity.

2. A bandage which was put over the nose: so called from its likeness to the claw of a hawk, or from the tightness of its grasp.

ACCIPITRI′NA. (From *accipiter*, the hawk.) The herb hawk-weed: which Pliny says was so called because hawks are used to scratch it, and apply the juice to their eyes to prevent blindness.

ACCLI′VIS. A muscle of the belly, so named from the oblique ascent of its fibres. See *Oliquus internus abdominis.*

Accouchement. The French word for the act of delivery.

Accoucheur. The French for a midwife.

ACCRETIO. (From *ad*, and *cresco*, to increase.) Accretion.

1. Nutrition; growth.

2. The growing together of parts naturally separate, as the fingers or toes.

ACCUBA′TIO. (From *accumbo*, to recline.) Childbed; reclining.

ACE′DIA. (From *α*, priv. and *κηδος*, care.) Carelessness, neglect in the application of medicines. Hippocrates sometimes uses this word, in his treatise on the Glands, to signify fatigue or trouble.

ACE′PHALUS. (*Acephalus*, *i.* m. *ακεφαλος*; from *α*, priv. and *κεφαλη*, a head.) Without a head. A term applied to a lusus naturæ, or monster, born without a head.

A′CER. (*Acer*, *eris.* neut.; from *acer*, sharp: because of the sharpness of its juice.) The name of a genus of plants in the Linnæan system. Class, *Polygamia*; Order, *Monœcia.*

ACER CAMPESTRE. The common maple. This tree yields a sweetish, soft, milky sap, which contains a salt with basis of lime, possessed, according to Sherer, of peculiar properties. It is white, semitransparent, not altered by the air, and soluble in one hundred parts of cold, or fifty of boiling water.

ACER PSEUDOPLATANUS. The maple-tree, falsely named sycamore. It is also called *Platanus traga.* This tree is common in England, though not much used in medicine. The juice, if drank while fresh, is said to be a good antiscorbutic. All its parts contain a saccharine fluid; and if the root or branches be wounded in the spring, a large quantity of liquor is discharged, which, when inspissated, yields a brown sort of sugar and syrup like molasses.

ACER SACCHARINUM. The sugar maple-tree. Large quantities of sugar are obtained from this tree in New-England and Canada, which is much used in France, where it is commonly known by the name of *Saccharum Canadense* or *Saccharum Acernum*, maple sugar. In has been supposed that all Europe might be supplied from the maple of America, which grows in great quantities in the western counties of all the middle States of the American Union. It is as tall as the oak, and from two to three feet in diameter; puts forth a white blossom in the spring, before any appearance of leaves; its small branches afford sustenance for cattle, and its ashes afford a large quantity of excellent potash. Twenty years are required for it to attain its full growth. Tapping does not injure it; but, on the contrary, it affords more syrup, and of a better quality, the oftener it is tapped. A single tree has not only survived, but flourished, after tapping, for forty years. Five or six pounds of sugar are usually afforded by the sap of one tree; though there are instances of the quantity exceeding twenty pounds. The sugar is separated from the sap either by freezing, by spontaneous evaporation, or by boiling. The latter method is the most used. Dr. Rush describes the process; which is simple, and practised without any difficulty by the farmers.

From frequent trials of this sugar, it does not appear to be in any respect inferior to that of the West Indies. It is prepared at a time of the year when neither insect, nor the pollen of plants, exists to vitiate it, as is the case with common sugar. From calculations grounded on facts, it is ascertained, that America is now capable of producing a surplus of one-eighth more than its own consumption.

ACERATE. *Aceras.* A salt formed of the acid of the *Acer campestre* with an alkaline, earthy, or metallic base.

ACE′RATOS. From *α*, neg. and *κεραω*, or *κεραννυμι*, to mix.) Unmixed; uncorrupted. This term is applied sometimes to the humours of the body by Hippocrates. Paulus Ægineta mentions a plaster of this name.

ACERB. (*Acerbus*; from *acer*, sharp.) A species of taste which consists in a degree of acidity, with an addition of roughness; properties common to many immature fruits.

ACE′RBITAS. Acerbness.

ACERIC ACID. A peculiar acid, said to exist in the juice of the common maple, *Acer campestre* of Linnæus. It is decomposed by heat, like the other vegetable acids.

ACE′RIDES. (From *α*, priv. and *κερος*, wax.) Soft plasters made without wax.

ACEROSUS. (From *acus*, a needle.) 1. Acerose: having the shape of a needle. Applied to leaves which are so shaped, as in *Pinus sylvestris* and *Juniperus communis.*

2. (From *acus*, chaff.) Chaffy: applied to coarse bread, &c.

ACESCENT. (*Acescens*; from *aceo*, to be sour or tart.) Turning sour or acid. Substances which readily run into the acid fermentation, are so said to be; as some vegetable and animal juices and infusions. The suddenness with which this change is effected, during a thunder-storm, even in corked bottles, has not been accounted for. In some morbid states of the stomach, also, it proceeds with astonishing rapidity.

A′CESIS. (From *ακεομαι*, to cure.) 1. A remedy or cure.

2. The herb water-sage; so called from its supposed healing qualities.

ACE′STA. (From *ακεομαι*, to cure.) Distempers which are easily cured.

ACE′STIS. Borax.

ACE′STORIS. (From *ακεομαι*, to cure. It strictly signifies a female physician, and is used for a midwife.

ACETA′BULUM. (*Acetabulum*, *i.* n.; from *acetum*, vinegar: so called because it resembles the *acetabulum*, or old saucer, in which vinegar was held for the use of the table.) A name given by Latin writers to the cup-like cavity of the os innominatum, which receives the head of the thigh-bone. See *Innominatum os.*

ACETA'RIUM. (From *acetum*, vinegar: because it is mostly made with vinegar.) A salad or pickle.

ACE'TAS. (*Acetas, tis*; f. from *acetum*, vinegar.) An acetate. A salt formed by the union of the acetic acid, with a salifiable base. Those used in medicine are the acetates of ammonia, lead, potassa, and zinc.

ACETAS AMMONIÆ. Acetate of ammonia. See *Ammonia acetatis liquor.*

ACETAS PLUMBI. Acetate of lead. See *Plumbi acetas* and *Plumbi acetatis liquor.*

ACETAS POTASSÆ. Acetate of potassa. See *Potassæ acetas.*

ACETAS ZINCI. A metallic salt composed of zinc and acetic acid. It is used by some as an astringent against inflammation of the eyes, urethra, and vagina, diluted in the same proportion as the sulphate of zinc.

Acetate. See *Acetas.*

Acetate of Ammonia. See *Ammoniæ acetatis liquor.*

Acetate of Potassa. See *Potassæ acetas.*

Acetate of Zinc. See *Acetas zinci.*

Acetated vegetable Alcali. See *Potassæ acetas.*

Acetated volatile Alcali. See *Ammoniæ acetatis liquor.*

ACETIC ACID. *Acidum aceticum.* The same acid which, in a very dilute and somewhat impure state, is called vinegar. Acetic acid is found combined with potassa in the juices of a great many plants; particularly the *Sambucus nigra, Phœnix dactilifera, Galium Verum*, and *Rhus Typhinus.* "Sweat, urine, and even fresh milk, contain it. It is frequently generated in the stomachs of dyspeptic patients. Almost all dry vegetable substances, and some animal, subjected in close vessels to a red heat, yield it copiously. It is the result likewise of a spontaneous fermentation, to which liquid vegetable, and animal matters are liable. Strong acids, as the sulphuric and nitric, develope the acetic by their action on vegetables. It was long supposed, on the authority of Boerhaave, that the fermentation which forms vinegar is uniformly preceded by the vinous. This is a mistake, cabbages sour in water, making sour crout; starch, in starch-makers' sour waters; and dough itself, without any previous production of wine.

"The varieties of acetic acid known in commerce are four: 1. Wine vinegar. 2. Malt vinegar. 3. Sugar vinegar. 4. Wood vinegar.

"We shall describe first the mode of making these commercial articles, and then that of extracting the absolute acetic acid of the chemist, either from these vinegars or directly from chemical compounds, of which it is a constituent.

"The following is the plan of making vinegar at present practised in Paris. The wine destined for vinegar is mixed in a large tun with a quantity of wine lees, and the whole being transferred into cloth-sacks, placed within a large iron bound vat, the liquid matter is extruded through the sacks by superincumbent pressure. What passes through is put into large casks, set upright, having a small aperture in their top. In these it is exposed to the heat of the sun in summer, or to that of a stove in winter. Fermentation supervenes in a few days. If the heat should then rise too high, it is lowered by cool air and the addition of fresh wine. In the skilful regulation of the fermentative temperature consists the art of making good wine vinegar. In summer the process is generally completed in a fortnight: in winter, double the time is requisite. The vinegar is then run off into barrels, which contain several chips of birchwood. In about a fortnight it is found to be clarified, and is then fit for the market. It must be kept in close casks.

"The manufacturers at Orleans prefer wine of a year old for making vinegar. But if by age the wine has lost its extractive matter, it does not readily undergo the acetous fermentation. In this case, acetification, as the French term the process, may be determined by adding slips of vines, bunches of grapes, or green woods."

"Almost all the vinegar of the north of France being prepared at Orleans, the manufactory of that place has acquired such celebrity, as to render their process worthy of a separate consideration. The Orleans' casks contain nearly 400 pints of wine. Those which have been already used are preferred. They are placed in three rows, one over another, and in the top have an aperture of two inches' diameter, kept always open. The wine for acetification is kept in adjoining casks, containing beech shavings, to which the lees adhere. The wine thus clarified is drawn off to make vinegar. One hundred pints of good vinegar, boiling hot, are first poured into each cask, and left there for eight days. Ten pints of wine are mixed in, every eight days, till the vessels are full. The vinegar is allowed to remain in this state fifteen days before it is exposed to sale.

"The *used* casks called *mothers*, are never emptied more than half, but are successively filled again, to acetify new portions of wine. In order to judge if the *mother* works, the vinegar-makers plunge a spatula into the liquid; and according to the quantity of froth which the spatula shows, they add more or less wine. In summer, the atmospheric heat is sufficient. In winter, stoves heated to about 75° Fahr. maintain the requisite temperature in the manufactory.

"In some country districts, the people keep, in a place where the temperature is mild and equable, *a vinegar cask*, into which they pour such wine as they wish to acetify; and it is always preserved full by replacing the vinegar drawn off, by new wine. To establish this household manufacture, it is only necessary to buy at first a small cask of good vinegar.

"At Gand, a vinegar from beer is made, in which the following proportions of grain are found to be most advantageous:—

1880 Paris lbs. malted barley.
700 — wheat.
500 — buck-wheat.

These grains are ground, mixed, and boiled, along with twenty-seven casks full of river water, for three hours. Eighteen casks of good beer for vinegar are obtained. By a subsequent decoction, more fermentable liquid is extracted, which is mixed with the former. The whole brewing yields 3000 English quarts.

"In this country, vinegar is usually made from malt. By mashing with hot water, 100 gallons of wort are extracted in less than two hours from 1 boll of malt. When the liquor has fallen to the temperature of 75° Fahr. 4 gallons of the barm of beer are added. After thirty-six hours it is racked off into casks, which are laid on their sides, and exposed, with their bung-holes loosely covered, to the influence of the sun in summer; but in winter they are arranged in a stove-room. In three months this vinegar is ready for the manufacture of sugar of lead. To make vinegar for domestic use, however, the process is somewhat different. The above liquor is racked off into casks placed upright, having a false cover, pierced with holes fixed at about a foot from their bottom. On this a considerable quantity of *rape*, or the refuse from the makers of British wine, or otherwise a quantity of low-priced raisins, is laid. The liquor is turned into another barrel every twenty-four hours, in which time it has begun to grow warm. Sometimes, indeed, the vinegar is fully fermented, as above, without the rape, which is added towards the end, to communicate flavour. Two large casks are in this case worked together, as is described long ago by Boerhaave, as follows :—

“‘Take two large wooden vats, or hogsheads ; and in each of these, place a wooden grate or hurdle, at the distance of a foot from the bottom. Set the vessel upright ; and on the grate, place a moderately close layer of green twigs, or fresh cuttings of the vine. Then fill up the vessel with the footstalks of grapes, commonly called the rape, to the top of the vessel, which must be left quite open.

“‘Having thus prepared the two vessels, pour into them the wine to be converted into vinegar, so as to fill one of them quite up, and the other but half-full. Leave them thus for twenty-four hours, and then fill up the half-filled vessel with liquor from that which is quite full, and which will now in its turn only be left half-full. Four-and-twenty hours afterwards, repeat the same operation ; and thus go on, keeping the vessels alternately full and half-full during twenty-four hours, till the vinegar be made. On the second or third day, there will arise in the half-filled vessel a fermentative motion, accompanied with a sensible heat, which will gradually increase from day to day. On the contrary, the fermenting motion is almost imperceptible in the full vessel ; and as the two vessels are alternately full and half-full, the fermentation is by this means in some measure interrupted, and is only renewed every other day in each vessel.

“‘When this motion appears to have entirely ceased, even in the half-filled vessel, it is a sign that the fermentation is finished ; and therefore the vinegar is then to be put into casks close stopped, and kept in a cool place.

“‘A greater or less degree of warmth accelerates or checks this, as well as the spirituous fermentation. In France, it is finished in about fifteen days, during the summer ; but if the heat of the air be very great, and exceed the twenty-fifth degree of Reaumur's thermometer (88 1 4° Fahr.) the half-filled vessel must be filled up every twelve hours ; because, if the fermentation be not so checked in that time, it will become violent, and the liquor will be so heated, that many of the spirituous parts, on which the strength of the vinegar depends, will be dissipated so that nothing will remain after the fermentation but a vapid liquor, sour indeed, but effete. The better to prevent the dissipation of the spirituous parts, it is a proper and usual precaution to close the mouth of the half-filled vessel in which the liquor ferments, with a cover made of oak wood. As to the full vessel, it is always left open that the air may act freely on the liquor it contains : for it is not liable to the same inconveniences, because it ferments but very slowly.’

“Good vinegar may be made from a weak syrup, consisting of 18 oz. of sugar to every gallon of water. The yeast and rape are to be here used as above described. Whenever the vinegar (from the taste and flavour) is considered to be complete, it ought to be decanted into tight barrels or bottles, and well secured from access of air. A momentary ebullition before it is bottled is found favourable to its preservation. In a large manufactory of malt vinegar, a considerable revenue is derived from the sale of yeast to the bakers.

“Vinegar obtained by the preceding methods has more or less of a brown colour, and a peculiar but rather grateful smell. By distillation in glass vessels the colouring matter, which resides in a mucilage, is separated, but the fragrant odour is generally replaced by an empyreumatic one. The best French wine vinegars, and also some from malt, contain a little alcohol, which comes over early with the watery part, and renders the first product of distillation scarcely denser, sometimes even less dense, than water. It is accordingly rejected. Towards the end of the distillation the empyreuma increases. Hence only the intermediate portions are retained as distilled vinegar. Its specific gravity varies from 1.005 to 1.015, whilst that of common vinegar of equal strength varies from 1.010 to 1.025.

“A crude vinegar has been long prepared for the calico printers, by subjecting wood in iron retorts to a strong red heat.”

“The acetic acid of the chemist may be prepared in the following modes : 1st. Two parts of fused acetate of potassa with one of the strongest oil of vitriol yield, by slow distillation from a glass retort into a refrigerated receiver, concentrated acetic acid. A small portion of sulphurous acid, which contaminates it, may be removed by re-distillation, from a little acetate of lead. 2d. Or four parts of good sugar of lead, with one part of sulphuric acid treated in the same way, afford a slightly weaker acetic acid. 3d. Gently calcined sulphate of iron, or green vitriol, mixed with sugar of lead in the proportion of 1 of the former to 2 1-2 of the latter, and carefully distilled from a porcelain retort into a cooled receiver, may be also considered a good economical process. Or without distillation, if 100 parts of well dried acetate of lime be cautiously added to 60 parts of strong sulphuric acid, diluted with 5 parts of water, and digested for 24 hours, and strained, a good acetic acid, sufficiently strong for every ordinary purpose, will be obtained.

“The distillation of acetate of copper or of lead *per se*, has also been employed for obtaining strong acid. Here, however, the product is mixed with a portion of the fragrant pyro-acetic spirit, which it is troublesome to get rid of. Undoubtedly the best process for the strong acid is that first described, and the cheapest the second or third. When of the utmost possible strength its sp. gravity is 1.062. At the temperature of 50° F. it assumes the solid form, crystallising in oblong rhomboidal plates. It has an extremely pungent odour, affecting the nostrils and eyes even painfully, when its vapour is incautiously snuffed up. Its taste is eminently acid and acrid. It excoriates and inflames the skin.

“The purified wood vinegar, which is used for pickles and culinary purposes, has commonly a specific gravity of about 1.009 ; when it is equivalent in acid strength to good wine or malt vinegar of 1.014. It contains about 1-20 of its weight of absolute acetic acid, and 19-20 of water. But the vinegar of fermentation = 1.014 will become only 1.023 in acetate, from which, if 0.005 be subtracted for mucilage or extractive, the remainder will agree with the density of the acetate from wood. A glass hydrometer of Fahrenheit's construction is used for finding the specific gravities. It consists of a globe of about 3 inches' diameter, having a little ballast ball drawn out beneath, and a stem above of about 3 inches long, containing a slip of paper with a transverse line in the middle, and surmounted with a little cup for receiving weights or poises. The experiments on which this instrument, called an *Acetometer*, is constructed, have been detailed in the sixth volume of the Journal of Science."

"An acetic acid of very considerable strength may also be prepared by saturating perfectly dry charcoal with common vinegar, and then distilling. The water easily comes off, and is separate at first; but a stronger heat is required to expel the acid. Or by exposing vinegar to very cold air, or to freezing mixtures, its water separates in the state of ice, the interstices of which are occupied by a strong acetic acid, which may be procured by draining. The acetic acid or radical vinegar of the apothecaries, in which they dissolve a little camphor, or fragrant essential oil, has a specific gravity of about 1.070. It contains fully 1 part of water to 2 of the crystallised acid. The pungent smelling salt consists of sulphate of potash moistened with that acid.

"Acetic acid acts on *tin*, *iron*, *zinc*, *copper*, and *nickel;* and it combines readily with the *oxydes* of many *other metals*, by mixing a solution of their sulphates with that of an acetate of lead."

"Acetic acid dissolves *resins*, *gum-resins*, *camphor*, and *essential oils*."

"Acetic acid and common vinegar are sometimes fraudulently mixed with sulphuric acid to give them strength. This *adulteration* may be detected by the addition of a little chalk, short of their saturation. With pure vinegar the calcareous base forms a limpid solution, but with sulphuric acid a white insoluble gypsum. Muriate of barytes is a still nicer test. British fermented vinegars are allowed by law to contain a little sulphuric acid, but the quantity is frequently exceeded. Copper is discovered in vinegars by supersaturating them with ammonia, when a fine blue colour is produced; and lead by sulphate of soda, hydrosulphurets, sulphuretted hydrogen, and gallic acid. None of these should produce any change on genuine vinegar." See *Lead.*

"Salts consisting of the several bases, united in definite proportions to acetic acid, are called *acetates.* They are characterised by the pungent smell of vinegar, which they exhale on the affusion of sulphuric acid; and by their yielding on distillation in a moderate red heat a very light, odorous, and combustible liquid called pyro-acetate (SPIRIT;) which see. They are all soluble in water; many of them so much so as to be uncrystallisable. About 30 different acetates have been formed, of which only a very few have been applied to the uses of life.

"The acetic acid unites with all the *alkalies* and most of the *earths;* and with these bases it forms compounds, some of which are crystallisable, and others have not yet been reduced to a regularity of figure. The salts it forms are distinguished by their great solubility; their decomposition by fire, which carbonises them; the spontaneous alteration of their solution; and their decomposition by a great number of acids, which extricate from them the acetic acid in a concentrated state. It unites likewise with most of the metallic oxides.

"With *barytes* the saline mass formed by the acetic acid does not crystallise; but, when evaporated to dryness, it deliquesces by exposure to air. This mass is not decomposed by acid of arsenic. By spontaneous evaporation, however, it will crystallise in fine transparent prismatic needles, of a bitterish acid taste, which do not deliquesce when exposed to the air, but rather effloresce.

"With *potassa* this acid unites, and forms a deliquescent salt scarcely crystallisable, called formerly *foliated earth of tartar*, and *regenerated tartar.* The solution of this salt, even in closely stopped vessels, is spontaneously decomposed: it deposits a thick, mucous, flocculent sediment, at first gray, and at length black; till at the end of a few months nothing remains in the liquor but carbonate of potassa, rendered impure by a little coaly oil.

"With *soda* it forms a crystallisable salt, which does not deliquesce. This salt has very improperly been called mineral foliated earth. According to the new nomenclature, it is acetate of soda.

"The salt formed by dissolving *chalk* or other calcareous earth in distilled vinegar, formerly called *salt of chalk*, or *fixed vegetable sal ammoniac*, and by Bergman *calx acetata*, has a sharp bitter taste, appears in the form of crystals resembling somewhat ears of corn, which remain dry when exposed to the air, unless the acid has been superabundant, in which case they deliquesce."

Of the *acetate of strontian* little is known but that it has a sweet taste, is very soluble, and is easily decomposed by a strong heat.

"The salt formed by uniting vinegar with *ammonia*, called by the various names of *spirit of Mindererus*, *liquid sal ammoniac*, *acetous sal ammoniac*, and by Bergman *alkali volatile acetatum*, is generally in a liquid state, and is commonly believed not to be crystallisable, as in distillation it passes entirely over into the receiver. It nevertheless may be reduced into the form of small needle-shaped crystals, when this liquor is evaporated to the consistence of a syrup."

"With *magnesia* the acetic acid unites, and after a perfect saturation, forms a viscid saline mass, like a solution of gum-arabic, which does not shoot into crystals, but remains deliquescent, has a taste sweetish at first, and afterwards bitter, and is soluble in spirit of wine. The acid of this saline mass may be separated by distillation without addition.

"*Glucine* is readily dissolved by acetic acid. This solution, Vauquelin informs us, does not crystallise; but is reduced by evaporation to a gummy substance, which slowly becomes dry and brittle; retaining a kind of ductility for a long time. It has a saccharine and pretty strongly astringent taste, in which that of vinegar however is distinguishable.

"*Yttria* dissolves readily in acetic acid, and the solution yields by evaporation crystals of acetate of yttria."

"*Alumine* obtained by boiling alum with alkali, and edulcorated by digesting in an alkaline lixivium, is dissolved by distilled vinegar in a very inconsiderable quantity."

"*Acetate of zircone* may be formed by pouring acetic acid on newly precipitated zircone. It has an astringent taste."

"Vinegar dissolves the true gums, and partly the gum-resins, by means of digestion.

"Boerhaave observes, that vinegar by long boiling dissolves the flesh, cartilages, bones, and ligaments of animals."—*Ure's Chemical Dictionary.*

Moderately rectified pyrolignous acid has been recommended for the preservation of animal food; but the empyreumatic taint it communicates to bodies immersed in it, is not quite removed by their subsequent ebullition in water. See *Acid, Pyrolignous.*

The utility of vinegar as a condiment for preserving and seasoning both animal and vegetable substances in various articles of food is very generally known. It affords an agreeable beverage, when combined with water in the proportion of a table-spoonful of the former to half a pint of the latter. It is often employed as a medicine in inflammatory and putrid diseases, when more active remedies cannot be procured. Relief has likewise been obtained in hypochondriacal and hysteric affections, in vomiting, fainting, and hiccough, by the application of vinegar to the mouth. If this fluid be poured into vessels and placed over the gentle heat of a lamp in the apartments of the sick, it greatly contributes to disperse foul or mephitic vapours, and consequently to purify the air. Its anticontagious powers are now little trusted to, but its odour is employed to relieve nervous headache, fainting fits, or sickness occasioned by crowded rooms.

As an external application, vinegar proves highly efficacious when joined with farinaceous substances, and applied as a cataplasm to sprained joints; it also forms an eligible lotion for inflammations of the surface, when mixed with alcohol and water in about equal proportions. Applied to burns and scalds, it is said to be highly serviceable whether there is a loss of substance or not, and to quicken the exfoliation of carious bone. (Gloucester Infirmary.) Mixed with an infusion of sage, or with water, it forms a popular and excellent gargle for an inflamed throat, also for an injection to moderate the fluor albus. Applied cold to the nose in cases of hæmorrhage, also to the loins and abdomen in menorrhagia, particularly after parturition, it is said to be very serviceable. An imprudent use of vinegar internally is not without considerable inconveniencies. Large and frequent doses injure the stomach, coagulate the chyle, and produce not only leanness, but an atrophy. When taken to excess by females to reduce a corpulent habit, tubercles in the lungs and a consumption have been the consequence.

ACETIFICATION. (*Acetificatio*; from *acetum*, vinegar, and *fio*, to make.) The action or operation by which vinegar is made.

ACETOMETER. An instrument for estimating the strength of vinegars. See *Acetic Acid.*

ACETO'SA. (From *acesco*, to be sour.) Sorrel. A genus of plants in some systems of botany. See *Rumex.*

ACETOSE'LLA. (From *acetosa*, sorrel: so called from the acidity of its leaves.) Wood-sorrel. See *Oxalis acetosella.*

ACETOUS. (*Acetosus*; from *acetum*, vinegar.) Of or belonging to vinegar.

Acetous Acid. See *Acetum.*

Acetous Fermentation. See *Fermentation.*

ACE'TUM. (*Acetum, i.* n.; from *acer*, sour.) Vinegar. A sour liquor obtained from many vegetable substances dissolved in boiling water, and from fermented and spirituous liquors, by exposing them to heat and contact with air; under which circumstances they undergo the acid fermentation, and afford the liquor called vinegar. Common vinegar consists of acetic acid combined with a large portion of water, and with this are in solution portions of gluten, mucilage, sugar, and extractive matter, from which it derives its colour, and frequently some of the vegetable acids, particularly the malic and the tartaric. See *Acetic Acid.*

ACETUM AROMATICUM. Aromatic vinegar. A preparation of the Edinburgh Pharmacopœia, thought to be an improvement of what has been named *thieves' vinegar.*

Take of the dried tops of rosemary, the dried leaves of sage, of each four ounces; dried lavender flowers, two ounces; cloves, two drachms; distilled vinegar, eight pounds. Macerate for seven days, and strain the expressed juice through paper. Its virtues are antiseptic, and it is a useful composition to smell at in crowded courts of justice, hospitals, &c. where the air is offensive.

ACETUM COLCHICI. Vinegar of meadow-saffron. Take of fresh meadow-saffron root sliced, an ounce; acetic acid, a pint; proof spirit, a fluid ounce. Macerate the meadow-saffron root in the acid, in a covered glass vessel, for three days; then press out the liquor and set it by, that the feculencies may subside; lastly, add the spirit to the clear liquor. The dose is from ʒss to ʒiss.

ACETUM DISTILLATUM. See *Acidum aceticum dilutum.*

ACETUM SCILLÆ. Vinegar of squills. Take of squills recently dried, one pound; dilute acetic acid, six pints; proof spirit, half a pint. Macerate the squills with the vinegar in a glass vessel, with a gentle heat for twenty-four hours; then express the liquor and set it aside until the fæces subside. To the decanted liquor add the spirit. This preparation of squills is employed as an attenuant, expectorant, and diuretic. Dose, xv. to LX. drops.

A'CHEIR. (From *α*, neg. and *χειρ*, hand.) Without hands.

ACHI'COLUM. By this word Cælius Aurelianus, Acut. lib. iii. cap. 17. expresses the sudatorium of the ancient baths, which was a hot room where they used to sweat.

ACHILLE'A. (*Achillea, æ*, f. Αχιλλεια: from Achilles, who is said to have made his tents with it, or to have cured Telephus with it.) 1. The name of a genus of plants in the Linnæan system. Class, *Syngenesia*; Order, *Polygamia superflua.*

2. The pharmaceutical name of the milfoil. See *Achillea millefolium.*

ACHILLEA AGERATUM. Maudlin, or maudlin tansy. *Balsamita fæmina*; *Eupatorium Mesues.* This plant, the ageratum of the shops, is described by Linnæus as *Achillea:—foliis lanceolatis, obtusis, acutoserratis.* It is esteemed in some countries as anthelminthic and alterative, and is given in hepatic obstructions. It possesses the virtues of tansy.

ACHILLEA MILLEFOLIUM. The systematic name of the common yarrow, or milfoil. *Achillea*; *Myriophyllon*; *Chiliophyllon*; *Lumbus veneris*; *Militaris herba*; *Stratiotes*; *Carpentaria*; *Speculum veneris.* The leaves and flowers of this indigenous plant, *Achillea—foliis bipinnatis nudis; laciniis linearibus dentatis; caulibus superne sulcatis* of Linnæus, have an agreeable, weak, aromatic smell, and a bitterish, rough, and somewhat pungent taste. They are both directed for medicinal use in the Edinburgh Pharmacopœia; in the present practice, however, they are almost wholly neglected.

ACHILLEA PTARMICA. The systematic name of the sneeze-wort, or bastard pellitory. *Pseudopyrethrum*; *Pyrethrum sylvestre*; *Draco sylvestris*; *Tarchon sylvestris*; *Sternutamentoria*; *Dracunculus pratensis.* The flowers and roots of this plant, *Achillea—foliis lanceolatis, acuminatis, argute serratis*, have a hot biting taste, approaching to that of pyrethrum, with which they also agree in their pharmaceutical properties. Their principal use is as a masticatory and sternutatory.

Achillea foliis pinnatis. See *Genipi verum.*

ACHI'LLES. The son of Peleus and Thetis, one of the most celebrated Grecian heroes. A tendon is named after him, and also a plant with which he is said to have cured Telephus.

Achillis tendo. The tendon of the gastrocnemii muscles. So called, because, as fable reports, Thetis, the mother of Achilles, held him by that part when she dipped him in the river Styx, to make him invulnerable. Homer describes this tendon, and some writers suppose it was thus named by the ancients, from their custom of calling every thing *Achillean*, that had any extraordinary strength or virtue. Others say it was named from its action in conducing to swiftness of pace, the term importing so much. The tendon of Achilles is the strong and powerful tendon of the heel which is formed by the junction of the gastrocnemius and soleus muscles, and which extends along the posterior part of the tibia from the calf to the heel. See *Gastrocnemius externus*, and *Gastrocnemius internus*.

When this tendon is unfortunately cut or ruptured, as it may be in consequence of a violent exertion, or spasm of the muscles of which it is a continuation, the use of the leg is immediately lost, and unless the part be afterwards successfully united, the patient must remain a cripple for life. When the tendon has been cut, the division of the skin allows the accident to be seen. When the tendon has been ruptured, the patient hears a sound like that of the smack of a whip, at the moment of the occurrence. In whatever way the tendon has been divided, there is a sudden incapacity, or at least an extreme difficulty, either of standing or walking. Hence the patient falls down, and cannot get up again. Besides these symptoms there is a very palpable depression between the ends of the tendon; which depression is increased when the foot is bent, and diminished, or even quite removed when the foot is extended. The patient can spontaneously bend his foot, none of the flexor muscles being interested. The power of extending the foot is still possible, as the peronei muscles, the tibialis posticus, and long flexors, remain perfect, and may perform this motion. The indications are to bring the ends of the divided parts together, and to keep them so, until they have become firmly united. The first object is easily fulfilled by putting the foot in a state of complete extension; the second, namely, that of keeping the ends of the tendon in contact, is more difficult. It seems unnecessary to enumerate the various plans devised to accomplish these ends. The following is Desault's method: After the ends of the tendon had been brought into contact by moderate flection of the knee, and complete extension of the foot, he used to fill up the hollows on each side of the tendon with soft lint and compresses. The roller applied to the limb, made as much pressure on these compresses as on the tendon, and hence this part could not be depressed too much against the subjacent parts. Desault next took a compress about two inches broad, and long enough to reach from the toes to the middle of the thigh, and placed it under the foot, over the back of the leg and lower part of the thigh. He then began to apply a few circles of a roller round the end of the foot, so as to fix the lower extremity of the longitudinal compress; after covering the whole foot with the roller, he used to make the bandage describe the figure of 8, passing it under the foot and across the place where the tendon was ruptured, and the method was finished by encircling the limb upward with the roller as far as the upper end of the longitudinal compress.

A'CHLYS. (Αλυς.) Darkness; cloudiness. An obsolete term, generally applied to a close, foggy air, or a mist.

1. Hippocrates, de Morbis Mulierum, lib. ii. signifies by this word air, condensed air in the womb.

2. Galen interprets it of those, who, during sickness, lose that lustre and loveliness observed about the pupil of the eye in health.

3. Others express it by an ulcer on the pupil of the eye, or the scar left there by an ulcer.

4. It means also an opacity of the cornea; the same as the caligo cornea of Dr. Cullen.

Achma'dium. Antimony.

ACHME'LLA. See *Spilanthus acmella.*

A'CHNE. An obsolete term applied to

1. Chaff.

2. Scum or froth of the sea.

3. A white mucus in the fauces, thrown up from the lungs, like froth.

4. A whitish mucilage in the eyes of those who have fevers, according to Hippocrates.

5. It signifies also lint.

A'CHOLUS. (From *α*, priv. and χολη, bile.) Deficient in bile.

A'CHOR. (*Achor, oris.* m. αχωρ, qu. αχνωρ; from αχνη, bran: according to Blanchard it is derived from *α*, priv. and χωρος, space, as occupying but a small compass.) *Lactumen*; *Abas*; *Acores*; *Cerion*; *Favus*; *Crusta lactea* of authors. The scald-head; so called from the branny scales thrown off it. A disease which attacks the hairy scalp of the head, for the most part, of young children, forming soft and scaly eruptions. Dr. Willan, in his description of different kinds of pustules, defines the achor, a pustule of intermediate size between the phlyzacium and psydracium, which contains a straw-coloured fluid, having the appearance and nearly the consistence of strained honey. It appeared most frequently about the head, and is succeeded by a dull white or yellowish scab. Pustules of this kind, when so large as nearly to equal the size of phlyzacia, are termed ceria or favi, being succeeded by a yellow, semi-transparent, and sometimes cellular, scab, like a honeycomb. The achor differs from the favus and tinea only in the degree of virulence. It is called favus when the perforations are large; and tinea when they are like those which are made by moths in cloth; but generally by tinea is understood a dry scab on the hairy scalp of children, with thick scales and an offensive smell. When this disorder affects the face, it is called crusta lactea or milk scab. Mr. Bell, in his Treatise on Ulcers, reduces the tinea capitis and crusta lactea to some species of herpes, *viz.* the herpes pustulosus, differing only in situation.

ACHORISTOS. Inseparable. This term was applied by the ancients, to symptoms, or signs, which are inseparable from particular things. Thus, softness is inseparable from humidity; hardness from fragility; and a pungent pain in the side is an inseparable symptom of a pleurisy.

ACHRAS. The name of a genus of plants in the Linnæan system. Class, *Hexandria*; Order, *Monogynia*. The sapota plum-tree.

Achras sapota. The systematic name of the tree which affords the oval-fruited sapota, seeds of which are sometimes given in the form of emulsion in calculous complaints. It is a native of South America, and bears a fruit like an apple, which has, when ripe, a luscious taste, resembling that of the marmalade of quinces.

whence it is called natural marmalade. The bark of this, and the *Achras mammosa* is very astringent, and is used medicinally under the name of *Cortex jamaicensis*.

ACHREI'ON Useless. Applied by Hippocrates to the limbs which, through weakness, become useless.

ACHROI'A. A paleness.

A'CHYRON. Αχυρον. This properly signifies bran, or chaff, or straw. Hippocrates, de Morbis Mulierum, most probably means by this word, bran. Achyron also signifies a straw, hair, or any thing that sticks upon a wall.

A'CIA. (From ακη, a point.) A needle with thread in it for chirurgical operations.

A'CICYS. Weak, infirm, or faint. In this sense it is used by Hippocrates, De Morb. lib. iv.

ACID. (*Asidum, i.* n.) 1. That which impresses upon the organs of taste a sharp or sour sensation. The word *sour*, which is usually employed to denote the simple impression, or lively and sharp sensation produced on the tongue by certain bodies, may be regarded as synonymous to the word *acid*. The only difference which can be established between them, is, that the one denotes a weak sensation, whereas the other comprehends all the degrees of force, from the least perceptible to the greatest degrees of causticity: thus we say that verjuice, gooseberries, or lemons, are *sour;* but we use the word acid to express the impression which the nitric, sulphuric, or muriatic acids make upon the tongue.

2. Acids are an important class of chemical compounds. In the generalisation of facts presented by Lavoisier and the associated French chemists, it was the leading doctrine that acids resulted from the union of a peculiar combustible base called the *radical*, with a common principle technically called oxygen, or the *acidifier*. This general position was founded chiefly on the phenomena exhibited in the formation and decomposition of sulphuric, carbonic, phosphoric, and nitric acids; and was extended by a plausible analogy to other acids, the radicals of which were unknown.

"I have already shown," says Lavoisier, "that phosphorus is changed by combustion into an extremely light, white, flaky matter. Its properties are likewise entirely altered by this transformation; from being insoluble in water, it becomes not only soluble, but so greedy of moisture as to attract the humidity of the air with astonishing rapidity. By this means it is converted into a liquid, considerably more dense, and of more specific gravity than water. In the state of phosphorus before combustion, it had scarcely any sensible taste; by its union with oxygen, it acquires an extremely sharp and sour taste; in a word, from one of the class of combustible bodies, it is changed into an incombustible substance, and becomes one of those bodies called acids.

"This property of a combustible substance, to be converted into an acid by the addition of oxygen, we shall presently find belongs to a great number of bodies. Wherefore strict logic requires that we should adopt a common term for indicating all these operations which produce analogous results. This is the true way to simplify the study of science, as it would be quite impossible to bear all its specific details in the memory if they were not classically arranged. For this reason we shall distinguish the conversion of phosphorus into an acid by its union with oxygen, and in general every combination of oxygen with a combustible substance, by the term *oxygenation;* from this I shall adopt the verb to oxygenate; and of consequence shall say, that in oxygenating phosphorus, we convert it into an acid.

"Sulphur also, in burning, absorbs oxygen gas; the resulting acid is considerably heavier than the sulphur burnt; its weight is equal to the sum of the weights of the sulphur which has been burnt, and of the oxygen absorbed; and, lastly, this acid is weighty, incombustible, and miscible with water in all proportions.

"I might multiply these experiments, and show, by a numerous succession of facts, that all acids are formed by the combustion of certain substances; but I am prevented from doing so in this place by the plan which I have laid down, of proceeding only from facts already ascertained to such as are unknown, and of drawing my examples only from circumstances already explained. In the mean time, however, the examples above cited may suffice for giving a clear and accurate conception of the manner in which acids are formed. By these it may be clearly seen that oxygen is an element common to them all, and which constitutes or produces their acidity; and that they differ from each other according to the several natures of the oxygenated or acidified substances. We must, therefore, in every acid, carefully distinguish between the acidifiable base, which de Morveau calls the radical, and 'the acidifying principle or oxygen.'" *Elements*, p. 115.

"Although we have not yet been able either to compose or to decompound this acid of sea salt, we cannot have the smallest doubt that it, like all other acids, is composed by the union of oxygen with an acidifiable base. We have, therefore, called this unknown substance the muriatic base, or muriatic radical." P. 122. 5th *Edition*.

Berthollet maintains, that Lavoisier had given too much latitude to the idea of oxygen being the universal acidifying principle. "In fact," says he, "it is carrying the limits of analogy too far to infer, that all acidity, even that of the muriatic, fluoric, and boracic acids, arises from oxygen, because it gives acidity to a great number of substances. Sulphuretted hydrogen, which really possesses the properties of an acid, proves directly that acidity is not in all cases owing to oxygen. There is no better foundation for concluding that hydrogen is the principle of alcalinity, not only in the alcalies, properly so called, but also in magnesia, lime, strontian, and barytes, because ammonia appears to owe its alcalinity to hydrogen.

"These considerations prove that oxygen may be regarded as the most usual principle of acidity, but that this species of affinity for the alcalies may belong to substances which do not contain oxygen; that we must not, therefore, always infer, from the acidity of a substance, that it contains oxygen, although this may be an inducement to suspect its existence in it; still less should we conclude, because a substance contains oxygen, that it must have acid properties; on the contrary, the acidity of an oxygenated substance shows that the oxygen has only experienced an incomplete saturation in it, since its properties remain predominant."

This generalisation of the French chemists concerning oxygen, was first experimentally combated by Sir Humphry Davy, in a series of dissertations published in the Philosophical Transactions.

"His first train of experiments was instituted with the view of operating by voltaic electricity on muriatic and other acids freed from water. Substances which are now known by the names of chlorides of phosphorus and tin, but which he then supposed to contain dry muriatic acid, led him to imagine that intimately combined water was the real acidifying principle, since acid properties were immediately developed in the above substances by the addition of that fluid, though previously they exhibited no acid powers. In July, 1810, however, he advanced those celebrated views concerning acidification, which, in the opinion of the best judges, display an unrivalled power of scientific research. The conclusions to which these led him, were incompatible with the general hypothesis of Lavoisier. He demonstrated that oxymuriatic acid is, as far as our knowledge extends, a *simple* substance, which may be classed in the same order of natural bodies as oxygen gas, being determined like oxygen to the positive surface in voltaic combinations, and like oxygen combining with inflammable substances, producing heat and light. The combinations of oxymuriatic acid with inflammable bodies were shown to be analogous to oxydes and acids in their properties and powers of combination, but to differ from them in being, for the most part, decomposable by water: and, finally, that oxymuriatic acid has a stronger attraction for most inflammable bodies than oxygen. His preceding decomposition of the alcalies and earths having evinced the absurdity of that nomenclature which gives to the general and essential constituent of alcaline nature, the term oxygen or acidifier; his new discovery of the simplicity of oxymuriatic acid, showed the theoretical system of chemical language to be equally vicious in another respect. Hence this philosopher most judiciously discarded the appellation oxymuriatic acid, and introduced in its place the name chlorine, which merely indicates an obvious and permanent character of the substance, its greenish yellow colour. The more recent investigations of chemists on fluoric, hydriodic, and hydrocyanic acids, have brought powerful analogies in support of the chloridic theory, by showing that hydrogen alone can convert certain undecompounded bases into acids well characterised, without the aid of oxygen."

"After these observations on the nature of acidity, we shall now state the general properties of the acids.

"1. The taste of these bodies is for the most part sour, as their name denotes; and in the stronger species it is acrid and corrosive.

"2. They generally combine with water in every proportion, with a condensation of volume and evolution of heat.

"3. With a few exceptions they are volatilised or decomposed at a moderate heat.

"4. They usually change the purple colours of vegetables to a bright red.

"5. They unite in definite proportions with the alcalies, earths, and metallic oxydes, and form the important class of salts. This may be reckoned their characteristic and indispensable property."

"Thenard has lately succeeded in communicating to many acids *apparently* a surcharge of oxygen, and thus producing a supposed new class of bodies, the *oxygenised acids*, which are, in reality, combinations of the ordinary acids with oxygenised water, or with the deutoxide of hydrogen."

"The class of acids has been distributed into three orders, according as they are derived from the mineral, the vegetable, or the animal kingdom. But a more specific distribution is now requisite. They have also been arranged into those which have a single, and those which have a compound basis or radical. This arrangement is not only vague, but liable in other respects to considerable objections. The chief advantage of a classification is to give general views to beginners in the study, by grouping together such substances as have analogous properties or composition. These objects will be tolerably well attained by the following divisions and subdivisions.

"1st. Acids from inorganic nature, or which are procurable without having recourse to animal or vegetable products.

"2d. Acids elaborated by means of organization.

"The first group is subdivided into three families: 1st. Oxygen acids; 2d. Hydrogen acids; 3d. Acids destitute of both these supposed acidifiers.

Family 1st.—Oxygen acids.
Section 1st, Non-metallic.

1. Boracic.
2. Carbonic.
3. Chloric.
4. Perchloric?
5. Chloro-Carbonic.
6. Nitrous.
7. Hyponitric.
8. Nitric.
9. Iodic.
10. Iodo-Sulphuric.
11. Hypophosphorous.
12. Phosphorous.
13. Phosphatic.
14. Phosphoric.
15. Hyposulphurous.
16. Sulphurous.
17. Hyposulphuric.
18. Sulphuric.
19. Cyanic?

Section 2d, Oxygen acids.—Metallic.

1. Arsenic.
2. Arsenious.
3. Antimonious.
4. Antimonic.
5. Chromic.
6. Columbic.
7. Molybdic.
8. Molybdous.
9. Tungstic.

Family 2d.—Hydrogen acids.

1. Fluoric.
2. Hydriodic.
3. Hydrochloric, or Muriatic.
4. Ferroprussic.
5. Hydroselenic.
6. Hydroprussic, or Hydro-cyanic.
7. Hydrosulphurous.
8. Hydrotellurous.
9. Sulphuroprussic.

Family 3d.—Acids without Oxygen or Hydrogen.

1. Chloriodic.
2. Chloroprussic, or Chlorocyanic.
3. Fluoboric.
4. Fluosilicic.

Division 2d.—Acids of Organic Origin.

1. Aceric.
2. Acetic.
3. Amniotic.
4. Benzoic.
5. Boletic.
6. Butyric.
7. Camphoric.
8. Caseic.
9. Cevadic.
10. Cholesteric.
11. Citric.
12. Delphinic.
13. Ellagic?
14. Formic.
15. Fungic.
16. Gallic.
17. Igasuric.
18. Kinic.
19. Laccic.
20. Lactic.
21. Lampic.
22. Lithic, or Uric.
23. Malic.
24. Meconic.
25. Menispermic.
26. Margaric.
27. Melassic?
28. Mellitic.
29. Moroxylic.
30. Mucic.
31. Nanceic?
32. Nitro-leucic.
33. Nitro-saccharic.
34. Oleic.
35. Oxalic.
36. Purpuric.
37. Pyrolithic.
38. Pyromalic.
39. Pyrotartaric.
40. Rosasic.
41. Saclactic.
42. Sebacic.
43. Suberic.
44. Succinic.
45. Sulphovinic?
46. Tartaric.

The acids of the last division are all decomposable at a red heat, and afford generally carbon, hydrogen, oxygen, and, in some few cases, also nitrogen. The mellitic is found like amber in wood coal, and, like it, is undoubtedly of organic origin."

Acid, aceric. See *Aceric acid.*

Acid, acetic. See *Acetum.*

Acid, acetous. See *Acetum.*

Acid, aerial. See *Carbonic acid.*

Acid, ætherial. See *Æthers.*

Acid, aluminous. See *Sulphuric acid.*

Acid, amniotic. See *Amniotic acid.*

Acid, animal. See *Acid.*

Acid, antimonic. See *Antimony.*

Acid, antimonous. See *Antimony.*

Acid of ants. See *Formic acid.*

Acid, arsenical. See *Arsenic.*

Acid, arsenious. See *Arsenic.*

Acid, benzoic. See *Benzoic acid.*

Acid, boletic. See *Boletic acid.*

Acid, boracic. See *Boracic acid.*

Acid, camphoric. See *Camphoric acid.*

Acid, carbonic. See *Carbonic acid.*

Acid, caseic. See *Caseic acid.*

Acid, cetic. See *Cetic acid.*

Acid, chloric. See *Chloric acid.*

Acid, chloriodic. See *Chloriodic acid.*

Acid, chlorous. See *Chlorous acid.*

Acid, chloro-carbonic. See *Chlorocarbonous acid* and *Phosgene.*

Acid, chloro-cyanic. See *Chloro-cyanic acid.*

Acid, chloro-prussic. See *Chloro-cyanic acid.*

Acid, chromic. See *Chromic acid.*

Acid, citric. See *Citric acid.*

Acid, columbic. See *Columbic acid.*

Acid, cyanic. See *Prussic acid.*

Acid, dephlogisticated muriatic. See *Chlorine.*

Acid, dulcified. Now called Æther.

Acid, ellegic. See *Ellagic acid.*

Acid, ferro-chyazic. See *Ferro-chyazic acid.*

Acid, ferro-prussic. See *Ferro-prussic acid.*

Acid, ferruretted chyazic. See *Ferro-prussic acid.*

Acid, fluoboric. See *Fluoboric acid.*

Acid, fluoric. See *Fluoric acid.*

Acid, fluoric, silicated. See *Fluoric acid.*

Acid, fluosilicic. See *Fluoric acid.*

Acid, formic. See *Formic acid.*

Acid, fungic. See *Fungic acid.*

Acid, gallic. See *Gallic acid.*

Acid, hydriodic. See *Hydriodic acid.*

Acid, hydrochloric. See *Muriatic acid.*

Acid, hydrocyanic. See *Prussic acid.*

Acid, hydrofluoric. See *Fluoric acid.*

Acid, hydrophosphorous. See *Phosphorous acid.*

Acid, hydrophtoric. See *Fluoric acid.*

Acid, hydrosulphuric. See *Sulphuretted hydrogen.*

Acid, hydrothionic. See *Sulphuretted hydrogen.*

Acid, hyponitrous. See *Hyponitrous acid.*

Acid, hypophosphorus. See *Hypophosphorous acid.*

Acid, hyposulphuric. See *Hyposulphuric acid.*

Acid, hyposulphurous. See *Hyposulphurous acid.*

Acid, igasuric. See *Igasuric acid.*

Acid, imperfect. These acids are so called in the chemical nomenclature, which are not fully saturated with oxygen. Their names are ended in Latin by *osum*, and in English by *ous*: e. g. *acidum nitrosum*, or nitrous acid.

Acid, iodic. See *Iodic acid.*

Acid, iodosulphuric. See *Iodosulphuric acid.*

Acid, kinic. See *Kinic acid.*

Acid, krameric. See *Krameric acid.*

Acid, laccic. See *Laccic acid.*

Acid, lactic. See *Lactic acid.*

Acid, lampic. See *Lampic acid.*

Acid, lethic. See *Lethic acid.*

Acid, malic. See *Malic acid.*

Acid, manganesic. See *Manganesic acid.*

Acid, margaritic. See *Margaritic acid.*

Acid, meconic. See *Meconic acid.*

Acid, mellitic. See *Mellitic acid.*

Acid, menispermic. See *Menispermic acid.*

Acid of milk. See *Mucic acid.*

Acid, mineral. Those acids which are found to exist in minerals, as the sulphuric, the nitric, &c. See *Acid.*

Acid, molybdic. See *Molybdic acid.*

Acid, molybdous. See *Molybdous acid.*

Acid, moroxylic. See *Moroxylic acid.*

Acid, mucic. See *Mucic acid.*

Acid, mucous. See *Mucic acid.*

Acid, muriatic. See *Muriatic acid.*

Acid, muriatic, dephlogisticated.

Acid, nanceic. See *Nanceic acid.*

Acid of nitre. See *Nitric acid.*

Acid, nitric. See *Nitric acid.*

Acid, nitro-leucic. See *Nitro-leucic acid.*

Acid, nitro-muriatic. See *Nitro-muriatic acid.*

Acid, nitro-saccharine. See *Nitro-saccharic acid.*

Acid, nitro-sulphuric. See *Nitro-sulphuric acid.*

Acid, nitrous. See *Nitrous acid.*

Acid, Œnothionic. See *Œnothionic acid.*

Acid, oleic. See *Oleic acid.*

Acid, oxalic. See *Oxalic acid.*

Acid, oxiodic. See *Iodic acid.*

Acid, oxychloric. See *Perchloric acid.*

Acid, oxymuriatic. See *Chlorine.*

Acid, perchloric. See *Perchloric acid.*

Acid, perfect. An acid is termed perfect in the chemical nomenclature, when it is completely saturated with oxygen. Their names are ended in Latin by *icum*, and in English by *ic*: e. g. *acidum nitricum*, or *nitric* acid.

Acid, perlate. See *Perlate acid.*

Acid, pernitrous. See *Hyponitrous acid.*

Acid, phosphatic. See *Phosphatic acid.*

Acid, phosphoric. See *Phosphoric acid.*

Acid, phosphorous. See *Phosphorous acid.*

Acid, prussic. See *Prussic acid.*

Acid, purpuric. See *Purpuric acid.*

Acid, pyro-acetic. See *Pyro-acetic acid.*

Acid, pyrocitric. See *Pyrocitric acid.*

Acid, pyroligneous. See *Pyro-ligneous acid.*

Acid, pyromucous. See *Pyro-mucic acid.*

Acid, pyrotartarous. See *Pyrotartaric acid.*

Acid, rheumic. See *Rheumic acid.*

Acid, saccho-lactic. See *Mucic acid.*

Acid, saclactic. See *Mucic acid.*

Acid, sebacic. See *Sebacic acid.*

Acid, selenic. See *Selenic acid.*

Acid, silicated, fluoric.

Acid sorbic. See *Sorbic acid.*

Acid, stannic. See *Stannic acid.*

Acid, stibic. See *Stibic acid.*

Acid, stibious. See *Stibious acid.*

Acid, suberic. See *Suberic acid.*

Acid, succinic. See *Succinic acid.*

Acid of sugar. See *Oxalic acid.*

Acid, sulpho-cyanic. See *Sulphuro-prussic acid.*

Acid, sulphovinous. See *Sulphovinic acid.*

Acid, sulphureous. See *Sulphureous acid.*

Acid, sulphuretted chyazic. See *Sulphuro-prussic acid.*

Acid, sulphuric. See *Sulphuric acid.*

Acid of Tartar. See *Tartaric acid.*

Acid, tartaric. See *Tartaric acid.*

Acid, telluric. See *Telluric acid.*

Acid, tungstic. See *Tungstic acid.*

Acid, uric. See *Lithic acid.*

Acid, vegetable. Those which are found in the vegetable kingdom, as the citric, malic, acetic, &c. See *Acid.*

Acid of vinegar. See *Acetum.*

Acid of vinegar, concentrated. See *Acetum.*

Acid of vitriol. See *Sulphuric acid.*

Acid, vitriolic. See *Sulphuric acid.*

Acid, zumic. See *Zumic acid.*

ACIDIFIABLE. Capable of being converted into an acid by an acidifying principle. Substances possessing this property are called *radicals* and *acidifiable bases.*

ACIDIFICATION. (*Acidificatio*; from *acidum*, an acid.) The formation of an acid; also the impregnating of any thing with acid properties.

ACIDIFYING. See *Acid.*

ACIDIMETRY. The measurement of the strength of acids. This is effected by saturating a given weight of them with an alcaline base; the quantity of which requisite for the purpose, is the measure of their power.

ACIDITY. *Aciditas.* Sourness.

ACIDULOUS. *Acidula*, Latin; *acidule*, French. Slightly acid: applied to those salts in which the base is combined with such an excess of acid, that they manifestly exhibit acid properties, as the supertartrate and the supersulphate of potassa.

Acidulous waters. Mineral waters, which contain so great a quantity of carbonic acid gas, as to render them acidulous, or gently tart to the taste. See *Mineral waters.*

ACIDULUS. Acidulated. Any thing blended with an acid juice in order to give it a coolness and briskness.

A'CIDUM. (*Acidum*, i. n; from *aceo*, to be sour.) An acid. See *Acid.*

ACIDUM ACETICUM. See *Acidum aceticum dilutum.*

ACIDUM ACETICUM DILUTUM. Dilute acetic acid. Take of vinegar, a gallon.

Distil the acetic acid in a sand bath, from a glass retort into a receiver also of glass, and kept cold; throw away the first pint, and keep for use the six succeeding pints, which are distilled over.

In this distillation, the liquor should be kept moderately boiling, and the heat should not be urged too far, otherwise the distilled acid will have an empyreumatic smell and taste, which it ought not to possess. If the acid be prepared correctly, it will be colourless, and of a grateful, pungent, peculiar acid taste. One fluid ounce ought to dissolve at least ten grains of carbonate of lime, or white marble. This liquor is the *acetum distillatum*; the *acidum acetosum* of the London Pharmacopœia of 1787, and the *acidum aceticum* of that of 1822, and the *acidum aceticum dilutum* of the present. The compounds of the acid of vinegar, directed to be used by the new London Pharmacopœia, are *acetum colchici, acetum scillæ, ceratum plumbi acetatis, liquor ammoniæ acetatis, liquor plumbi acetatis, liquor plumbi acetatis dilutis, oxymel, oxymel scillæ, potassæ acetas*, and the *cataplasma sinapis.*

ACIDUM ACETICUM CONCENTRATUM. When the acid of vinegar is greatly concentrated, that is, deprived of its water, it is called concentrated acid of vinegar, and radical vinegar.

Distilled vinegar may be concentrated by freezing: the congelation takes place at a temperature below 28 degrees, more or less, according to its strength; and the congealed part is merely ice, leaving, of course, a stronger acid. If this be exposed to a very intense cold, it shoots into crystals; which, being separated, liquefy, when the temperature rises; and the liquor is limpid as water, extremely strong, and has a highly pungent acetous odour. This is the pure acid of the vinegar; the foreign matter remaining in the uncongealed liquid.

Other methods are likewise employed to obtain the pure and concentrated acid. The process of Westendorf, which has been often followed, is to saturate soda with distilled vinegar; obtain the acetate by crystallisation; and pour upon it, in a retort, half its weight of sulphuric acid. By applying heat, the acetic acid is distilled over; and, should there be any reason to suspect the presence of any sulphuric acid, it may be distilled a second time, from a little acetate of soda. According to Lowitz, the best way of obtaining this acid pure, is to mix three parts of the acetate of soda with eight of supersulphate of potassa; both salts being perfectly dry, and in fine powder, and to distil from this mixture in a retort, with a gentle heat.

It may also be obtained by distilling the verdigris of commerce, with a gentle heat. The concentrated acid procured by these processes, was supposed to differ materially from the acetous acids obtained by distilling vinegar; the two acids were regarded as differing in their degree of oxygenisement, and were afterwards distinguished by the names of acetous and acetic acids. The acid distilled from verdigris was supposed to derive a quantity of oxygen from the oxyde of copper, from which it was expelled. The experiments of Adet have, however, proved the two acids to be identical; the acetous acid, therefore, only differs from the acetic acid in containing more water, rendering it a weaker acid, and of a less active nature. There exists, therefore, only one of acid vinegar, which is the acetic; its compounds are termed *acetates.*

ACIDUM ACETOSUM. See *Acetum.*

ACIDUM ÆTHEREUM. See *Sulphuric acid.*

ACIDUM ALUMINOSUM. (So called, because it exists in alum.) See *Sulphuric acid.*

ACIDUM ARSENICUM. See *Arsenic.*

ACIDUM BENZOICUM. Benzoic acid. The London Pharmacopœia directs it to be made thus:—Take of gum benzoin a pound and a half: fresh lime, four ounces: water, a gallon and a half: muriatic acid, four fluid ounces. Rub together the benzoin and lime; then boil them in a gallon of the water, for half an hour, constantly stirring; and, when it is cold, pour off the liquor. Boil what remains a second time, in four pints of water, and pour off the liquor as before. Mix the liquors, and boil down to half, then strain through paper, and add the muriatic acid gradually, until it ceases to produce a precipitate. Lastly, having poured off the liquor, dry the powder in a gentle heat; put it into a proper vessel, placed in a sand bath; and by a very gentle fire, sublime the benzoic acid. In this process a solution of benzoate of lime is first obtained; the muriatic acid then, abstracting the lime, precipitates the benzoic acid, which is crystallised by sublimation.

The Edinburgh Pharmacopœia forms a benzoate of soda, precipitates the acid by sulphuric acid, and afterwards crystallises it by solution in hot water, which dissolves a larger quantity than cold.

Benzoic acid has a strong, pungent, aromatic, and peculiar odour. Its crystals are ductile, not pulverisable; it sublimes in a moderate heat, forming a white irritating smoke. It is soluble in about twenty-four times its weight of boiling water, which, as it cools, precipitates 19-20ths of what it had dissolved. It is soluble in alcohol.

Benzoic acid is very seldom used in the cure of diseases; but now and then it is ordered as a stimulant against convulsive coughs and difficulty of breathing. The dose is from one grain to five.

ACIDUM BORACICUM. See *Boracic acid.*

ACIDUM CARBONICUM. See *Carbonic acid.*

ACIDUM CATHOLICON. See *Sulphuric acid.*

ACIDUM CITRICUM. See *Citric acid.*

ACIDUM MURIATICUM. See *Muriatic acid.*

ACIDUM MURIATICUM OXYGENATUM. See *Oxygenised muriatic acid.*

ACIDUM NITRICUM. See *Nitric acid.*

ACIDUM NITRICUM DILUTUM. Take of nitric acid a fluid ounce; distilled water nine fluid ounces. Mix them.

ACIDUM NITROSUM. See *Nitrous acid.*

ACIDUM PHOSPHORICUM. See *Phosphoric acid.*

ACIDUM PRIMIGENIUM. See *Sulphuric acid.*

ACIDUM SUCCINICUM. See *Succinic acid.*

ACIDUM SULPHUREUM. See *Sulphureous acid.*

ACIDUM SULPHURICUM. See *Sulphuric acid.*

ACIDUM SULPHURICUM DILUTUM. *Acidum vitriolicum dilutum. Spiritus vitrioli tenuis.* Take of sulphuric acid a fluid ounce and a half; distilled water, fourteen fluid ounces and a half. Add the water gradually to the acid.

ACIDUM TARTARICUM. See *Tartaric acid.*

ACIDUM VITRIOLICUM. See *Sulphuric acid.*

ACIDUM VITRIOLICUM DILUTUM. See *Acidum sulphuricum dilutum.*

A'CIES. Steel.

ACINACIFORMIS. (From *acinaces*, a Persian scimetar, or sabre, and *forma*, resemblance.) Acinaciform; shaped like a sabre, applied to leaves: as those of the *mysembryanthemum acinaciforme.*

ACINE'SIA. (From *ακινησια*, immobility.) A loss of motion and strength.

ACINIFORMIS. (From *acinus*, a grape, and *forma*, a resemblance.) Aciniform. A name given by the ancients to some parts which resembled the colour and form of an unripe grape, as the uvea of the eye, which was called *tunica acinosa*, and the choroid membrane of the eye, which they named *tunica aciniforma.*

A'CINUS. (*Acinus*, i. m.; a grape.) 1. In anatomy, those glands which grow together in clusters are called by some *acini glandulosi.*

2. In botany, a small berry, which, with several others, composes the fruit of the mulberry, blackberry, &c.

ACINUS BILIOSUS. The small glandiform bodies of the liver, which separate the bile from the blood, were formerly called *acini biliosi*: they are now, however, termed *penicilli.* See *Liver.*

ACMA'STICOS. A species of fever, wherein the heat continues of the same tenor to the end. *Actuarius.*

A'CME. (From *ακμη*, a point.) The height or crisis. A term applied by physicians to that period or state of a disease in which it is at its height. The ancients distinguished diseases into four stages: 1. The *Arche*, the beginning or first attack. 2. *Anabasis*, the growth. 3. The *Acme*, the height. 4. *Paracme*, or the decline of the disease.

ACMELLA. See *Spilanthus.*

A'CNE. Ακνη. *Acna.* A small pimple, or hard tubercle on the face. Foesius says, that it is a small pustule or pimple, which arises usually about the time that the body is in full vigour.

ACNE'STIS. (From *α*, priv. and *κναω*, to scratch.) That part of the spine of the back, which reaches from the metaphrenon, which is the part betwixt the shoulder-blades, to the loins. This part seems to have been originally called so in quadrupeds only, because they cannot reach it to scratch.

A'COE. Ακοη. The sense of hearing.

ACOE'LIUS. (From *α*, priv. and *κοιλια*, the belly.) Without belly. It is applied to those who are so wasted, as to appear as if they had no belly. *Galen.*

ACOE'TUS. Ακοιτος. An epithet for honey, mentioned by Pliny; because it has no sediment, which is called *κοιτη.*

ACO'NION. Ακονιον. A particular form of medicine among the ancient physicians, made of powders levigated, and probably like collyria for the disorders of the eyes.

ACONITA. (*Aconita, æ*, f.; from *aconitum* the name of a plant.) A poisonous vegetable principle, probably alcaline, recently extracted from the *aconitum napellus*, or wolf's bane, by Mons. Brandes. The details have not yet reached this country.

ACONITE. See *Aconitum.*

ACONI'TUM. (*Aconitum*, i. m. Of this name various derivations are given by etymologists; as, *ακονη*, a *whetstone* or *rock*, because it is usually found in barren and rocky places: *ακονιτος*, *α*, neg. and *κονις*, *dust*; because it grows without earth, or on barren situations; agreeable to Ovid's description, "Quæ quia nascuntur dura vivacia caute, Agrestes aconita vocant:" *ακοναω*, *to sharpen*; because it was used in medicines intended to quicken the sight: *ακων*, *ακη*, a *dart*; because they poison darts therewith: or, *ακονιζομαι*, to accelerate; for it hastens death.) Aconite. 1. A genus of plants in the Linnæan system, all the species of which have powerful effects on the human body. Class, *Polyandria*; Order, *Trygynia.*

2. The pharmacopœial name of the common, or blue, wolf's-bane. See *Aconitum napellus.*

ACONITUM ANTHORA. The root of this plant *Aconitum—floribus pentagynus, foliorum laciniis linearibus* of Linnæus, is employed medicinally. Its virtues are similar to those of the *aconitum napellus.*

ACONITUM NAPELLUS. Monk's-hood. Aconite. Wolf's-bane. *Camorum. Canicida. Cynoctanum. Actonitum;—foliorum laciniis linearibus, superne latioribus, linea exaratis* of Linnæus. This plant is cultivated in our gardens as an ornament, but is spontaneously produced in Germany, and some other northern parts of Europe. Every part is strongly poisonous, but the root is unquestionably the most powerful; and, when first chewed imparts a slight sensation of acrimony; but afterwards, an insensibility or stupor at the apex of the tongue, and a pungent heat of the lips, gums, palate, and fauces are perceived, followed with a general tremor and sensation of chilliness. The juice applied to a wound seemed to affect the whole nervous system; even by keeping it long in the hand, or on the bosom, we are told unpleasant symptoms have been produced. The fatal symptoms brought on by this poison are, convulsions, giddiness, insanity, violent purgings, both upwards and downwards, faintings, cold sweats, and death itself. Dr. Stoerk appears to be the first who gave the wolf's-bane internally, as a medicine; and since his experiments were published, 1762, it has been generally and successfully employed in Germany and the northern parts of Europe, particularly as a remedy for obstinate rheumatisms; and many cases are related where this disease was of several years' duration, and had withstood the efficacy of other powerful medicines, as mercury, opium, antimony, hemlock, &c. yet, in a short time, was entirely cured by the aconitum. Instances are also given us of its good effects in gout, scrophulous swellings, venereal nodes, amaurosis, intermittent fevers, paralysis, ulceration, and scirrhus. This plant has been generally prepared as an extract or inspissated juice, after the manner directed in the Pharmacopœia: its efficacy is much diminished on being long kept. Like all virulent medicines, it should first be administered in small doses. Stoerk recommends two grains of the extract to be rubbed into a powder, with two drachms of sugar, and to begin with ten grains of this powder, two or three times a day. We find, however, that the extract is often given from one grain to ten for a dose; and Stoll, Scherekbecker, and others, increased this quantity considerably. Instead of the extract, a tincture has been made of the dried leaves macerated in six times their weight of spirits of wine, and forty drops given for a dose. Some writers say that the napellus is not poisonous in Sweden, Poland, &c. but it should be noted that the species which is not poisonous, is the Aconitum lycoctonum of Linnæus.

Aco′nium. A little mortar.

Acopa. Dioscorides' name for the buck-bean or *Menyanthes trifoliata* of Linnæus.

A′COPON. (From *α*, priv. and *κοπος*, weariness.) It signifies originally whatever is a remedy against weariness, and is used in this sense by Hippocrates. Aph. viii. lib. ii. But in time, the word was applied to certain ointments. According to Galen and Paulus Ægineta, the *Acopa pharmaca* are remedies for indispositions of body which are caused by long or vehement motion.

Acopos. The name of a plant in Pliny, supposed to be the buck-bean or *Menyanthes trifoliata* of Linnæus.

A′COR. (*Acor, oris*, m.; from *aceo* to be sour.) Acidity. It is sometimes used to express that sourness in the stomach contracted by indigestion, and from whence flatulencies and acid belching arise.

Acor′dina. Indian tutty.

ACO′RIA. (From *α*, priv. and *κορεω*, to satiate.) Insatiability. In Hippocrates, it means good appetite and digestion.

ACORI′TES. (From *ακορον*, galangal.) *Acorites vinum.* A wine mentioned by Dioscorides, made with galangal, liquorice, &c. infused with wine.

ACORN. See *Quercus robur.*

Acortinus. A lupin.

A′CORUS. (*Acorus*, i. m.; *ακορον*, from *κορη*, the pupil; because it was esteemed good for the disorders of the eyes.) The name of a genus of plants in the Linnæan system. Class, *Hexandria*. Order, *Digynia.*

Acorus calamus. The systematic name of the plant which is also called *Calamus aromaticus*; *Acorus verus*; *Calamus odoratus*; *Calamus vulgaris*; *Diringa*; *Jacerantatinga*; *Typha aromatica*; *Clava rugosa.* Sweet-flag, or acorus. *Acorus*; *Scapi mucrone longissimo foliaceo* of Linnæus. The root has been long employed medicinally. It has a moderately strong aromatic smell; a warm, pungent, bitterish taste; and is deemed useful as a warm stomachic. Powdered, and mixed with some absorbent, it forms a useful and pleasant dentifrice.

Acorus palustris. See *Iris palustris.*

Acorus verus. See *Acorus calamus.*

Acorus vulgaris. See *Iris pallustris.*

A′COS. Ακος, from *ακεομαι*, to heal.) A remedy or cure.

ACO′SMIA. (From *α*, neg. and *κοσμος*, beautiful.) Baldness; ill-health: irregularity, particularly of the critical days of fevers.

Aco′ste. (From *ακοςη*, barley.) An ancient food made of barley.

ACOTYLE′DON. (*Acotyledon, onis*, n. from *α*, priv. and *κοτυληδων*. Without a cotyledon; applied in botany to a seed or plant which is not furnished with a cotyledon: *Semen acotyledon.* All the mosses are *plantæ acotyledones.*

ACOU′STIC. (*Acousticus*: from *ακουω*, to hear.) 1. Belonging to the ear or to sound.

2. That which is employed with a view to restore the sense of hearing, when wanting or diminished. No remedies of this kind given internally, are known to produce any uniform effect.

Acoustic nerve. See *Portio mollis.*

Acoustic duct. See *Meatus auditorius.*

Acra. (An Arabian word.) *Acrai.*

1. Excessive venereal appetite.

2. The time of menstruation.

Acræ′palos. See *Acraipala.*

Acrai′pala. (Ακραιπαλος. From *α*, neg. and *κραιπαλη*, surfeit.) Remedies for the effects of a debauch.

Acra′sia. (From *α*, and *κεραω*, to mix.) Unhealthiness; intemperance.

Acrati′a. (From *α*, and *κρατος*, strength.) Weakness or intemperance.

Acrati′sma. (From *ακρατον*, unmixed wine. The derivation of this word is the same as *Acrasia*, because the wine used on the occasion was not mixed with water.) A breakfast among the old Greeks, consisting of a morsel of bread, soaked in pure unmixed wine.

Acrato′meli. (From *ακρατον*, pure wine; and *μελι*, honey. Wine mixed with honey.

A′CRE. (From *ακρος*, extreme.) The extremity of the nose or any other part.

A′CREA. (From *ακρος*, extreme.) *Acroteria.* The extremities; the legs, arms, nose, and ears.

Acribei′a. (From *ακριβης*, accurate.) An exact and accurate description and diagnosis, or distinction, of diseases.

ACRID. *Acris.* A term employed in medicine to express a taste, the characteristic of which is pungency joined with heat.

ACRIMONY. (*Acrimonia*, from *acris*, acrid.) A quality in substances by which they irritate, corrode, or dissolve others. It has been supposed until very lately, there were acid and alkaline acrimonies in the blood, which produced certain diseases; and although the humoral pathology is nearly and improperly exploded, the term venereal acrimony, and some others, are still and must be retained.

A′CRIS. 1. Acrid. See *Acrid.*

2. Any fractured extremity.

Acri′sia. (From *α*, priv. and *κρινω*, to judge or separate.) A turbulent state of a disease, which will scarcely suffer any judgment to be formed thereof.

A′critus. (From *α*, neg. and *κρινω*, to judge.) A disease without a regular crisis, the event of which it is hazardous to judge.

ACROBY′STIA. (From *ακρος*, extreme, and *βυω*, to cover.) The prepuce which covers the extremity of the penis.

ACROCHEIRE′SIS. (From *ακρος* extreme, and *χειρ*, a hand.) An exercise among the ancients. Probably a species of wrestling, where they only held by the hands.

ACROCHEI′RIS. (From *ακρος*, extreme, and *χειρ*, a hand.) Gorræus says, it signifies the arm from the elbow to the ends of the fingers; *χειρ* signifying the arm, from the scapula to the fingers' end.

ACROCHO′RDON. (From *ακρος*, extreme, and *χορδη*, a string.) Galen describes it as a round excrescence on the skin, with a slender base; and that it hath its name because of its situation on the surface of the skin. The Greeks call that excrescence an *achrochordon*, where something hard concretes under the skin, which is rather rough, of the same colour as the skin, slender at the base and broader above. Their size rarely exceeds that of a bean.

ACROCO′LIA. (From ακρος, extreme, and κωλον, a limb.) These are the extremities of animals which are used in food, as the feet of calves, swine, sheep, oxen, or lambs, and of the broths of which jellies are frequently made. Castellus from Budæus adds, that the internal parts of animals are also called by this name.

ACHROLE′NION. Castellus says it is the same as *Olecranon.*

ACROMA′NIA. (From ακρος, extreme and μανια, madness.) Total or incurable madness.

ACRO′MION. (From ακρον, extremity, and ωμος, the shoulder.) A process of the scapula or shoulder-blade. See *Scapula.*

ACROMPHA′LIUM. (Ακρομφαλον; from ακρος, extreme, and ομφαλος, the navel.) *Acromphlaon.* The tip of the navel.

ACRO′MPHALON. See *Acromphalium.*

ACRO′NIA. (From ακρον, the extremity.) The amputation of an extremity, as a finger.

ACRO′PATHOS. (From ακρος, extreme, and ϖαθος, a disease.) *Acropathus.* It signifies literally a disease at the top or superior part. Hippocrates in his treatise De Superfœtatione, applies it to the internal orifice of the uterus; and in Prædict. lib. ii. to cancers which appear on the surface of the body.

ACRO′PATHUS. See *Acropathos.*

A′CROPIS. (From ακρον, the extremity, and οψ, the voice.) Imperfect articulation, from a fault in the tongue.

ACROPO′STHIA. (From ακρος, extreme, and ϖοσθη, the prepuce.) The extremity of the prepuce; or that part which is cut off in circumcision.

ACRO′PSILON. (From ακρος, extreme, and ψιλος, naked.) The extremity of the denuded glans penis.

ACRO′SPELOS. (From ακρος, extreme, and ϖελος, black, so called because its ears, or tops, are often of a blackish colour.) *Acrospelus.* The bromus Dioscoridis, or wild oat grass.

ACRO′SPELUS. See *Acrospelos.*

ACROTE′RIA. (From ακρος, extreme.) The extreme parts of the body; as the hands, feet, nose, ears, chin, &c.

ACROTERIA′SMUS. (From ακρος, *summus.*) The amputation of an extremity.

ACROTHYMIA. See *Acrothymion.*

ACROTHY′MION. (From ακρος, extreme, and ϑυμος, thyme. *Acrothymia. Acrothymium.* A sort of wart, described by Celsus, as hard, rough, with a narrow basis, and broad top; the top of the colour of thyme; it easily splits and bleeds.

ACROTHYMIUM. See *Acrothymion.*

ACROTICUS. (From ακρος, *summus*; whence ἀκρότης, ητος; *summitas*; *cacumen.*) A disease affecting the external surface.

ACROTICA. The name of an order in Good's Nosology.

ACROTISMUS. (*Acrotismus*; from ἀ, priv. and κροτος, *pulsus*, defect of pulse.) Acrotism or pulselessness. A term synonymous with asphyxia, and applied to a species of entasia in Good's Nosology.

ACTÆ′A. (From αγω, to break.) *Acte.* The elder-tree, so called from its being easily broken. See *Sambucus nigra.*

A′CTINE. The herb *Bunias* or *Napus.*

ACTINOBOLI′SMUS. (From ακτιν, a ray, and βαλλω, to cast out.) *Diradiatio.* Irradiation. It is applied to the spirits, conveying the inclinations of the mind to the body.

ACTINOLITE. The name of a mineral which is found in primitive districts.

ACTION. (*Actio*, *nis.* f.; from *ago*, to act.) 1. The operation or exertion of an active power.

2. Any faculty, power, or function. The actions or functions of the body are usually divided by physiologists into vital, animal, or natural. 1. The *vital* functions, or actions, are those which are absolutely necessary to life, and without which animals cannot exist; as the action of the heart, lungs, and arteries. 2. The *natural* functions are those which are instrumental in repairing the several losses which the body sustains: digestion, and the formation of chyle, &c. fall under this head. 3. The *animal* actions are those which we perform at will, as muscular motion, and all the voluntary motions of the body.

Independently of these properties, each part may be said to have an action peculiar to itself—for instance, the liver, by virtue of a power which is peculiar to it, forms continually a liquid which is called bile: the same thing takes place in the kidneys with regard to the urine. The voluntary muscles, in certain states, become hard, change their form, and contract. These are, however, referrible to vitality. It is upon these the attention of the physiologist ought to be particularly fixed. Vital action depends evidentally upon nutrition, and reciprocally, nutrition is influenced by vital action.—Thus, an organ that ceases to nourish, loses at the same time its faculty of acting; consequently, the organs the action of which is oftenest repeated possess a more active nutrition; and, on the contrary, those that act least, possess a much slower nutritive motion.

The mechanism of vital action is unknown. There passes into the organ that acts an insensible molecular motion, which is as little susceptible of description as the nutritive motion. Every vital action, however simple, is the same in this respect.

ACTON. A village four miles from London, where is a well that affords a purging water. This is one of the strongest purging waters near London; and has been drank in the quantity of from one to three pints in a morning, against scorbutic and cutaneous affections. This medical spring is no longer resorted to by the public.

ACTUAL. This word is applied to any thing endued with a property or virtue which acts by an immediate power inherent in it: it is the reverse of potential; thus, a red-hot iron or fire is called an actual cautery, in contradistinction from caustics, which are called potential cauteries. Boiling water is actually hot; brandy, producing heat in the body, is potentially hot, though of itself cold.

Actual cautery. The red-hot iron, or any red-hot substance. See *Actual.*

ACTUA′RIUS. This word was originally a title of dignity given to physicians at the court of Constantinople; but became afterwards the proper name of a celebrated Greek physician, John, (the son of Zachary, a Christian writer,) who flourished there about the 12th or 13th century. He is said to be the first Greek author who has treated of mild cathartics, as manna, cassia, &c. though they were long before in use among the Arabians. He appears also to have first noticed distilled waters. His works, however, are chiefly compiled from his predecessors.

ACTUATION. (From *ago*, to act.) That

change wrought on a medicine, or any thing taken into the body, by the vital heat, which is necessary, in order to make it act and have its effect.

ACU'ITAS. Acrimony.

ACUI'TIO. (From *acuo*, to sharpen.) The sharpening an acid medicine by an addition of something more acid; or, in general, the increasing the force of any medicine, by an addition of something that hath the same sort of operation in a greater degree.

ACULEA'TUS. (From *aculeus*, a prickle.) Prickly; covered with sharp-pointed bodies: applied to stems covered with sharp-pointed bodies, the prickles of which separate with the epidermis, as in *Rosa centifolia.*

ACU'LEUS. (From *acus*, a needle; from ἀκη, or ἀκις; *cuspis*, a point.) A prickle or sharp point. A species of armature with which the stems, branches, and other parts of several plants are furnished; as in the rose, raspberry, gooseberry. The *part* on which it grows is said to be aculeated, thus:—

Caulis aculeatus; as in the *Rosa canina.*

Folia aculeata; as in *Solanum marginatum.*

Calix aculeatus; as in *Solanum aculeatum.*

Stipula aculeata; as in *Rosa cinnamomia.*

Legumen aculeatum; as in *Scorpiurus muricata.*

From the *direction* it has:—

Aculeus rectus, not curved; as in *Rhamnus spina christi*, and *Rosa eglanteria.*

Aculeus incurvus, curved inward; as in *Mimosa cineraria.*

Aculeus recurvus, curved downward; as in *Rubus fruticosus*, and *Rosa rubiginosa.*

From the *number* in one place:—

Aculeus solitarius; as in *Rosa canina.*

Aculeus bifidus, or *geminatus*, in pairs; there being two joined at the basis; as in *Rhamnus spina christi.*

Aculeus trifidus, three in one; as in *Barbaris vulgaris.*

A'CULON. (From *α*, neg. and κυλοω, to roll round; so called because its fruit is not involved in a cup, or sheath, like others.)

Aculos. The fruit or acorn of the ilex.

A'CULOS. See *Aculon.*

ACU'MEN. 1. A point.

2. The extremity of a bone.

ACUMINATUS. (From *acuo*, to point.) Acuminate; or terminated by a point somewhat elongated. Applied by botanists to several parts of plants. An acuminate leaf is seen in the *Syringa vulgaris.* Acuminate leaf-stalk; as that of *Saxifraga stellaris.*

ACUPUNCTU'RA. (From *acus*, a needle, and *punctura*, a prick.) Acupuncture. A bleeding performed by making many small punctures.

ACUREB. Lead.

A'CURON. (From *α*, neg. and κυρω, to happen.) A name of the *Alisma*, because it produces no effect if taken internally.

ACUSPASTO'RIS. A name of the *Scandix anthriscus*, the shepherd's needle, or Venus's comb.

ACUTANGULARIS. *Acutangulatus.* Acutangular: applied to parts of plants, as *caulis acutangularis.*

ACUTE'. Sharply. Applied in natural history to express form; as *folium acutè dentatum; acutè emarginatus*, which means sharply dentate, and with sharp divisions.

ACUTENA'CULUM. (From *acus*, a needle, and *tenaculum*, a handle.) The handle for a needle, to make it penetrate easily when stitching a wound. Heister calls the *portaiguille* by this name.

ACUTUS. Sharp. 1. Used by naturalists to designate form; thus acute-leaved; as in *rumex acutus*, &c.

2. In pathology, it is applied to a sharp pungent pain; and to a disease which is attended with violent symptoms, terminates in a few days, and is attended with danger. It is opposed to a chronic disease, which is slow in its progress, and not so generally dangerous.

ACY'ISIS. (From *α*, neg. and κυω, to conceive.) A defect of conception, or barrenness in women.

A'CYRUS. (From *α*, priv. and κυρος, authority; so named from its little note in medicine.) The German leopard's bane. See *Arnica montana.*

ADÆMO'NIA. (From *α*, priv. and δαιμων, a genius of fortune.) See *Ademonia.*

ADAIGES. Sal-ammoniac.

Adam's Apple. See *Pomum Adami.*

ADAM'S NEEDLE. The roots of this plant, *Yucca gloriosa* of Linnæus, are thick and tuberous, and are used by the Indians instead of bread; being first reduced into a coarse meal. This, however, is only in times of scarcity.

ADAMANTINE SPAR. A stone remarkable for its extreme hardness, which comes from the peninsula of Hither India, and also from China.

A'DAMAS. (From *α*, neg. and δαμαω, to conquer; as not being easily broken.) The adamant or diamond, the most precious of all stones, and which was formerly supposed to possess extraordinary cordial virtues.

ADAMI'TA. *Adamitum.* A hard stone in the bladder.

ADAMITUM. See *Adamita.*

ADANSO'NIA. (From *Adanson* who first described the Æthiopian sour gourd, a species of this genus.) The name of a genus of plants. Class, *Polyandria;* Order, *Monadelphia.* Monkies' bread.

ADANSONIA DIGITATA. This is the only species of the genus yet discovered. It is called the Ethiopian sour gourd and monkies' bread. *Baobab. Bahobab.* It grows mostly on the west coast of Africa, from the Niger to the kingdom of Benin. The bark is called *lalo:* the negroes dry it in the shade; then powder and keep it in little cotton bags; and put two or three pinches into their food. It is mucilaginous, and generally promotes perspiration. The mucilage obtained from this bark is a powerful remedy against the epidemic fevers of the country that produces these trees; so is a decoction of the dried leaves. The fresh fruit is as useful as the leaves, for the same purposes.

ADA'RCES. (From *α*, neg. and δερκω, to see.) A saltish concretion found about the reeds and grass in marshy grounds in Galatia, and so called because it hides them. It is used to clear the skin with, in leprosies, tetters, &c. Dr. Plott gives an account of this production in his *Natural History of Oxfordshire.* It was formerly in repute for cleansing the skin from freckles.

ADARI'GES. An ammoniacal salt.

ADA'RNECK. Yellow orpiment.

Adarticulation. See *Arthrodia.*

ADDEPHA'GIA. (From αδην, abundantly, and φαγω, to eat.) Insatiability. A voracious appetite. See *Bulimia.*

ADDER. See *Coluber berus.*

ADDITAME'NTUM. (From *addo*, to add.) An addition to any part, which, though not always, is sometimes found. A term formerly employed as synonymous with *epiphysis*, but now only applied to two portions of sutures of the skull. See *Lambdoidal* and *Squamous Sutures.*

ADDITAMENTUM COLI. See *Appendicula cæci vermiformis.*

ADDUCENS. (From *ad*, and *duco*, to draw.) The name of some parts which draw those together to which they are connected.

ADDUCENS OCULI. See *Rectus internus oculi.*

ADDU′CTOR. (From *ad*, and *duco*, to draw.) A drawer or contractor. A name given to several muscles, the office of which is to bring forwards or draw together those parts of the body to which they are annexed.

ADDUCTOR BREVIS FEMORIS. A muscle of the thigh, which, with the *adductor longus* and *magnus femoris*, forms the *triceps adductor femoris. Adductor femoris secundus* of Douglas; *Triceps secundus* of Wenslow. It is situated on the posterior part of the thigh, arising tendinous from the os pubis, near its joining with the opposite os pubis below, and behind the adductor longus femoris, and is inserted, tendinous and fleshy, into the inner and upper part of the linea aspera, from a little below the trochanter minor, to the beginning of the insertion of the adductor longus femoris. See *Triceps adductor femoris.*

ADDUCTOR FEMORIS PRIMUS. See *Adductor longus femoris.*

ADDUCTOR FEMORIS SECUNDUS. See *Adductor brevis femoris.*

ADDUCTOR FEMORIS TERTIUS. See *Adductor magnus femoris.*

ADDUCTOR FEMORIS QUARTUS. See *Adductor magnus femoris.*

ADDUCTOR INDICIS PEDIS. An external interosseous muscle of the fore-toe, which arises tendinous and fleshy by two origins, from the root of the inside of the metatarsal bone of the fore-toe, from the outside of the root of the metatarsal bone of the great toe, and from the os cuneiforme internum. It is inserted, tendinous, into the inside of the root of the first joint of the fore-toe. Its use is to pull the fore-toe inwards from the rest of the small toes.

ADDUCTOR LONGUS FEMORIS. A muscle situated on the posterior part of the thigh, which, with the *adductor brevis*, and *magnus femoris*, forms the *triceps adductor femoris. Adductor femoris primus* of Douglas. *Triceps minus* of Winslow. It arises by a pretty strong roundish tendon, from the upper and interior part of the os pubis, and ligament of its synchondrosis, on the inner side of the pectineus, and is inserted along the middle part of the linea aspera. See *Triceps adductor femoris.*

ADDUCTOR MAGNUS FEMORIS. A muscle which, with the *adductor brevis femoris*, and the *adductor longus femoris*, forms the *Triceps adductor femoris; Adductor femoris tertius et quartus* of Douglas. *Triceps magnus* of Winslow. It arises from the symphysis pubis, and all along the flat edge of the thyroid foramen, from whence it goes to be inserted into the linea aspera throughout its whole length. See *Triceps adductor femoris.*

ADDUCTOR MINIMI DIGITI PEDIS. An internal interosseous muscle of the foot. It arises, tendinous and fleshy, from the inside of the root of the metatarsal bone of the little toe. It is inserted, tendinous, into the inside of the root of the first joint of the little toe. Its use is to pull the little toe inwards.

ADDUCTOR OCULI. See *Rectus internus oculi.*

ADDUCTOR POLLICIS. See *Adductor pollicis manûs.*

ADDUCTOR POLLICIS MANUS. A muscle of the thumb, situated on the hand. *Adductor pollicis; Adductor ad minimum digitum.* It arises, fleshy, from almost the whole length of the metacarpal bone that sustains the middle finger; from thence its fibres are collected together. It is inserted, tendinous, into the inner part of the root of the first bone of the thumb. Its use is to pull the thumb towards the fingers.

ADDUCTOR POLLICIS PEDIS. A muscle of the great toe, situated on the foot. *Antithenar* of Winslow. It arises, by a long, thin tendon, from the os calcis, from the os cuboides, from the os cuneiforme externum, and from the root of the metatarsal bone of the second toe. It is inserted into the external os sesamoideum, and root of the metatarsal bone of the great toe. Its use is to bring this toe nearer to the rest.

ADDUCTOR PROSTATÆ. A name given by Sanctorini to a muscle, which he also calls *Levator prostatæ*, and which Winslow calls *Prostaticus superior.* Albinus, from its office, had very properly called it *Compressor prostatæ.*

ADDUCTOR TERTII DIGITI PEDIS. An external interosseous muscle of the foot, that arises, tendinous and fleshy, from the roots of the metatarsal bones of the third and little toe. It is inserted, tendinous, into the outside of the root of the first joint of the third toe. Its use is to pull the third toe outward.

A′DEC. Sour milk, or butter-milk.

ADE′CIA. See *Adectos.*

ADE′CTOS. (From *α*, priv. and *δακνω*, to bite.) *Adecia.* An epithet of those medicines which relieve pain, by removing the uneasy situation caused by the stimulus of acrimonious medicines.

ADE′LPHIA. ('Αδελφια, a relation.) Hippocrates calls diseases by this name that resemble each other.

ADEMO′NIA. (From *α*, priv. and *δαιμων*, a genius, or divinity, or fortune.) *Adæmonia.* Hippocrates uses this word for uneasiness, restlessness, or anxiety felt in acute diseases, and some hysteric fits.

A′DEN. (*Aden, enis*, m.; αδην, a gland.)

1. A gland. See *Gland.*

2. A bubo. See *Bubo.*

ADENDE′NTES. An epithet applied to ulcers which eat and destroy the glands.

ADE′NIFORMIS. (From *aden*, a gland, and *forma*, resemblance.) Adeniform. 1. Glandiform, or resembling a gland.

2. A term sometimes applied to the prostate gland.

ADENO′GRAPHY. (*Adenographia;* from αδην, a gland, and γραφω, to write.) A treatise on the glands.

ADENOI′DES. (From αδην, a gland, and ειδος, resemblance.) Glandiform: resembling a gland. An epithet applied also to the prostate gland.

ADENO′LOGY. (*Adenologia;* from αδην, a gland, and λογος, a treatise.) The doctrine of the glands.

ADENOUS. (*Adenosus*, from αδην, a gland.) Gland-like.

ADEPHA′GIA. (From αδην, abundantly, and φαγω, to eat.) Insatiable appetite. See *Bulimia.*

A′DEPS. (*Adeps, ipis*, m. and f.) Fat. An oily secretion from the blood into the cells of the cellular membrane. See *Fat.*

ADEPS ANSERINUS. Goose-grease.

ADEPS PRÆPARATA. Prepared lard. Cut the lard into small pieces, melt it over a slow fire, and press it through a linen cloth.

ADEPS SUILLA. Hog's lard. This forms the basis of many ointments, and is used extensively for culinary purposes.

ADEPT. (From *Adipiscor*, to obtain.) 1. A skilful alchymist. Such are called so as pretend to some extraordinary skill in chemistry; but these have too often proved either enthusiasts or impostors.

2. The professors of the *Adepta Philosophia*, that philosophy the end of which is the transmutation of metals, and an universal remedy, were also called Adepts.

3. So Paracelsus calls that which treats of the diseases that are contracted by celestial operations, or communicated from heaven.

ADFLA'TUS. A blast; a kind of erysipelas, or St. Anthony's fire.

ADHÆSION. (*Adhesio; from adhæreo*, to stick to.) The growing together of parts.

ADHÆSIVE. (*Adhæsivus; from adhæro*, to stick to.) Having the property of sticking.

ADHÆSIVE INFLAMMATION. That species of inflammation which terminates by an adhesion of the inflamed surfaces.

ADHÆSIVE PLASTER. A plaster made of common litharge plaster and resin, is so called because it is used for its adhesive properties. See *Emplastrum resinæ.*

ADHATO'DA. (A Zeylanic term, signifying expelling a dead fœtus.) See *Justicia adhatoda.*

ADIACHY'TOS. (From *α*, neg. and *διαχὺω*, to diffuse, scatter, or be profuse.) Decent in point of dress. Hippocrates thinks the dress of a fop derogatory from the physician, though thereby he hide his ignorance, and obtain the good opinion of his patients.

ADIA'NTHUM. (*Adiantum, i.* n., *αδιαντον*; from *α*, neg. and *διαινω*, to grow wet: so called, because its leaves are not easily made wet.) The name of a genus of plants in the Linnæan system. Class, *Cryptogamia;* Order, *Filices.* Maidenhair.

ADIANTHUM AUREUM. The golden maidenhair. See *Polytrichum.*

ADIANTHUM CAPILLUS VENERIS. Maidenhair. The leaves of this plant are somewhat sweet and austere to the palate, and possess mucilaginous qualities. A syrup, the *syrop de capillaire* is prepared from them, which is much esteemed in France against catarrhs. Orange-flower water and a proportion of honey, it is said, are usually added. It acts chiefly as a demulcent, sheathing the inflamed sides of the glottis.

ADIANTHUM PEDATUM. *Adianthum canadense.* This plant is in common use in France for the same purposes as the common adianthum capillus veneris in this country, and appears to be far superior to it.

ADIAPHOROUS. *Adiaphorus.* A term which implies the same with neutral; and is particularly used of some spirits and salts, which are neither of an acid nor alcaline nature.

ADIAPNEU'STIA. (From the privative particle *α*, and *διαπνεω, perspiro.*) A diminution or obstruction of natural perspiration, and that in which the ancients chiefly placed the cause of fevers.

ADIARRHŒ'A. (From *α*, priv. and *διαῤῥεω*, to flow out or through.) A suppression of the necessary evacuations from the bowels.

ADIATHOROSUS. A spirit distilled from tartar. Obsolete.

ADIBAT. Mercury.

A'DICE. *Αδικη.* A nettle.

ADIPOCI'RE. (*Adipocera, æ.* f.; from *adeps*, fat, and *cera*, wax.) A particular spermaceti or fat-like substance formed by the spontaneous conversion of animal matter, under certain conditions. This conversion has long been well known, and is said to have been mentioned in the works of Lord Bacon. "On the occasion of the removal of a very great number of human bodies from the ancient burying-place des Innocens at Paris, facts of this nature were observed in the most striking manner. Fourcroy may be called the scientific discoverer of this peculiar matter, as well as the saponaceous ammoniacal substance contained in bodies abandoned to spontaneous destruction in large masses. This chemist read a memoir on the subject in the year 1789 to the Royal Academy of Sciences, from which the general contents are here abstracted.

"At the time of clearing the before mentioned burying-place, certain philosophers were specially charged to direct the precautions requisite for securing the health of the workmen. A new and singular object of research presented itself, which had been necessarily unknown to preceding chemists. It was impossible to foretell what might be the contents of a soil overloaded for successive ages with bodies resigned to the putrefactive process. This spot differed from common burying-grounds, where each individual object is surrounded by a portion of the soil. It was the burying-ground of a large district, wherein successive generations of the inhabitants had been deposited for upwards of three centuries. It could not be foreseen that the entire decomposition might be retarded for more than forty years; neither was there any reason to suspect that any remarkable difference would arise from the singularity of situation.

"The remains of the human bodies immersed in this mass of putrescence, were found in three different states, according to the time they had been buried, the place they occupied, and their relative situations with regard to each other. The most ancient were simply portions of bones, irregularly dispersed in the soil, which had been frequently disturbed. A second state, in certain bodies which had always been insulated, exhibited the skin, the muscles, the tendons, and aponeuroses, dry, brittle, hard, more or less gray, and similar to what are called mummies in certain caverns where this change has been observed, as in the catacombs at Rome, and the vault of the Cordeliers at Toulouse.

"The third and most singular state of these soft parts was observed in the bodies which filled the common graves or repositories. By this appellation are understood cavities of thirty feet in depth, and twenty on each side, which were dug in the burying-ground of the Innocents, and were appropriated to contain the bodies of the poor; which were placed in very close rows, each in its proper wooden bier. The necessity for disposing a great number, obliged the men charged with this employment to arrange them so near each other that these cavities might be considered when filled as an entire mass of human bodies separated only by two planks of about half an inch thick. Each cavity contained between one thousand and fifteen hundred. When one common grave of this magnitude was filled, a covering of about one foot deep of earth was laid upon it, and another excavation of the same sort was made at some distance. Each grave remained open about three years, which was the time required to fill it. According to the urgency of circumstances, the graves were again made on the same spot after an interval of time, not less than fifteen years, nor more than thirty. Experience had taught the workmen, that this time was not sufficient for the entire destruction of the bodies, and had shown them the progressive changes which form the object of Fourcroy's memoir.

"The first of these large graves, opened in the presence of this chemist, had been closed for fifteen years. The coffins were in good preservation, but a little settled, and the wood had a yellow tinge. When the covers of several were taken off, the bodies were observed at the bottom, leaving a considerable distance between their surface and the cover, and flattened as if they had suffered a strong compression. The linen which had covered them was slightly adherent to the bodies; and with the form of the different regions, exhibited on removing the linen, nothing but irregular masses of a soft ductile matter of a gray-white colour. These masses environed the bones on all sides, which had no solidity, but broke by any sudden pressure. The appearance of this matter, its obvious composition, and its softness, resembled common white cheese; and the resemblance was more striking from the print which the threads of the linen had made upon its surface. This white substance yielded to the touch, and became soft when rubbed for a time between the fingers.

"No very offensive smell was emitted from these bodies. The novelty and singularity of the spectacle, and the example of the grave-diggers, dispelled every idea either of disgust or apprehension. These men asserted that they never found this matter, by them called *gras* (fat,) in bodies interred alone; but that the accumulated bodies of the common graves only were subject to this change. On a very attentive examination of a number of bodies passed to this state, Fourcroy remarked, that the conversion appeared in different stages of advancement, so that, in various bodies, the fibrous texture and colour, more or less red, were discernible within the fatty matter; that the masses covering the bones were entirely of the same nature, offering indistinctly in all the regions a gray substance, for the most part soft and ductile, sometimes dry, always easy to be separated in porous fragments, penetrated with cavities, and no longer exhibiting any traces of membranes, muscles, tendons, vessels, or nerves. On the first inspection of these white masses, it might have been concluded that they were simply the cellular tissue, the compartments and vesicles of which they very well represented.

"By examining this substance in the different regions of the body; it was found that the skin is particularly disposed to this remarkable alteration. It was afterwards perceived that the ligaments and tendons no longer existed, or at least had lost their tenacity; so that the bones were entirely unsupported, and left to the action of their own weight. Whence their relative places were preserved in a certain degree by mere juxtaposition; the least effort being sufficient to separate them. The grave-diggers availed themselves of this circumstance in the removal of the bodies. For they rolled them up from head to feet, and by that means separated from each other the extremities of the bones, which had formerly been articulated. In all those bodies which were changed into the fatty matter, the abdominal cavity had disappeared. The teguments and muscles of this region being converted into the white matter, like the other soft parts, had subsided upon the vertebral column, and were so flattened as to leave no place for the viscera; and accordingly there was scarcely ever any trace observed in the almost obliterated cavity. This observation was for a long time matter of astonishment to the investigators. In vain did they seek, in the greater number of bodies, the place and substance of the stomach, the intestines, the bladder, and even the liver, the spleen, the kidneys, and the matrix in females. All these viscera were confounded together, and for the most part no traces of them were left. Sometimes only certain irregular masses were found, of the same nature as the white matter, of different bulks, from that of a nut to two or three inches in diameter, in the regions of the liver or of the spleen.

"The thorax likewise offered an assemblage of facts no less singular and interesting. The external part of this cavity was flattened and compressed like the rest of the organs; the ribs, spontaneously luxated in their articulations with the vertebræ, were settled upon the dorsal column; their arched part left only a small space on each side between them and the vertebræ. The pleura, the mediastinum, the large vessels, the aspera arteria, and even the lungs and the heart, were no longer distinguishable; but for the most part had entirely disappeared, and in their place nothing was seen but some parcels of the fatty substance. In this case, the matter which was the product of decomposition of the viscera charged with blood and various humours, differs from that of the surface of the body, and the long bones, in the red or brown colour possessed by the former. Sometimes the observers found in the thorax a mass irregularly rounded, of the same nature as the latter, which appeared to them to have arisen from the fat and fibrous substance of the heart. They supposed that this mass, not constantly found in all the subjects, owed its existence to a superabundance of fat in this viscus, where it was found. For the general observation presented itself, that, in similar circumstances, the fat parts undergo this conversion more evidently than the others, and afford a larger quantity of the white matter.

"The external region in females exhibited the glandular and adipose mass of the breast converted into the fatty matter, very white and very homogeneous.

"The head was, as has already been remarked, environed with the fatty matter; the face was no longer distinguishable in the greatest number of subjects; the mouth, disorganized, exhibited neither tongue nor palate; and the jaws, luxated and more or less displaced, were environed with irregular layers of the white matter. Some pieces of the same matter usually occupied the place of the parts situated in the mouth; the cartilages of the nose participated in the general alteration of the skin; the orbits, instead of eyes, contained white masses; the ears were equally disorganized; and the hairy scalp, having undergone a similar alteration to that of the other organs, still retained the hair. Fourcroy remarks incidentally, that the hair appears to resist every alteration much longer than any other part of the body. The cranium constantly contained the brain contracted in bulk; blackish at the surface, and absolutely changed like the other organs. In a great number of subjects which were examined, this viscus was never found wanting, and it was always in the above-mentioned state; which proves that the substance of the brain is greatly disposed to be converted into the fat matter.

"Such was the state of the bodies found in the burial-ground des Innocens. Its modifications were also various. Its consistence in bodies lately changed, that is to say, from three to five years, was soft and very ductile, containing a great quantity of water. In other subjects converted into this matter for a long time, such as those which occupied the cavities which had been closed thirty or forty years, this matter is drier, more brittle, and in denser flakes. In several, which were deposited in dry earth, various portions of the fatty matter had become semitransparent. The aspect, the granulated texture, and brittleness of this dried matter, bore a considerable resemblance to wax.

"The period of the formation of this substance had likewise an influence on its properties. In general, all that which had been formed for a long time was white, uniform, and contained no foreign substance, or fibrous remains; such, in particular, was that afforded by the skin of the extremities. On the contrary, in bodies recently changed, the fatty matter was neither so uniform nor so pure as in the former; but it was still found to contain portions of muscles, tendons, and ligaments, the texture of which, though already altered and changed in its colour, was still distinguishable. Accordingly, as the conversion was more or less advanced, these fibrous remains were more or less penetrated with the fatty matter, interposed as it were between the interstices of the fibres. This observation shows, that it is not merely the fat which is thus changed, as was natural enough to think at first sight. Other facts confirm this assertion. The skin, as has been remarked, becomes easily converted into very pure white matter, as does likewise the brain, neither of which has been considered by anatomists to be fat. It is true, nevertheless, that the unctuous parts, and bodies charged with fat, appear more easily and speedily to pass to the state under consideration. This was seen in the marrow, which occupied the cavities of the longer bones. And again, it is not to be supposed but that the greater part of these bodies had been emaciated by the illness which terminated their lives; notwithstanding which, they were all absolutely turned into this fatty substance.

"An experiment made by Poulletier de la Salle, and Fourcroy likewise, evinced that a conversion does not take place in the fat alone. Poulletier had suspended in his laboratory a small piece of the human liver, to observe what would arise to it by the contact of the air. It partly putrefied, without, however, emitting any very noisome smell. Larvæ of the dermestes and bruchus attacked and penetrated it in various directions; at last it became dry, and after more than ten years' suspension, it was converted into a white friable substance resembling dried agaric, which might have been taken for an earthy substance. In this state it had no perceptible smell. Poulletier was desirous of knowing the state of this animal matter, and experiment soon convinced him and Fourcroy that it was far from being in the state of an earth. It melted by heat, and exhaled in the form of vapour, which had the smell of a very fetid fat; spirit of wine separated a concrescible oil, which appeared to possess all the properties of spermaceti. Each of the three alcalies converted it into soap; and, in a word, it exhibited all the properties of the fatty matter of the burial-ground of the Innocents exposed for several months to the air. Here then was a glandular organ, which in the midst of the atmosphere had undergone a change similar to that of the bodies in the burying-place; and this fact sufficiently shows, that an animal substance which is very far from being of the nature of grease, may be totally converted into this fatty substance.

"Among the modifications of this remarkable substance in the burying-ground before mentioned, it was observed that the dry, friable, and brittle matter, was most commonly found near the surface of the earth, and the soft, ductile matter at a greater depth. Fourcroy remarks, that this dry matter did not differ from the other merely in containing less water, but likewise by the volatilization of one of its principles."

The grave-diggers assert, that near three years are required to convert a body into this fatty substance. But Dr. Gibbes of Oxford found, that lean beef secured in a running stream, was converted into this fatty matter at the end of a month. He judges from facts, that running water is most favourable to this process. He took three lean pieces of mutton, and poured on each a quantity of the three common mineral acids. At the end of three days, each was much changed: that in the nitric acid was very soft, and converted into the fatty matter; that in the muriatic acid was not in that time so much altered; the sulphuric acid had turned the other black. Lavoisier thinks that this process may hereafter prove of great use in society. It is not easy to point out what animal substance, or what situation, might be the best adapted for an undertaking of this kind.

The result of Fourcroy's inquiries into the ordinary changes of bodies recently deposited in the earth, was not very extensive. The grave-diggers informed him, that these bodies interred do not perceptibly change colour for the first seven or eight days; that the putrid process disengages elastic fluid, which inflates the abdomen, and at length bursts it; that this event instantly causes vertigo, faintness, and nausea in such persons as unfortunately are within a certain distance of the scene where it takes place; but that when the object of its action is nearer, a sudden privation of sense, and frequently death, is the consequence. These men are taught by experience, that no immediate danger is to be feared from the disgusting business they are engaged in, excepting at this period, which they regard with the utmost terror. They resisted every inducement and persuasion which these philosophers made use of, to prevail on them to assist their researches into the nature of this active and pernicious vapour. Fourcroy takes occasion from these facts, as well as from the pallid and unwholesome appearance of the grave-diggers, to reprobate burials in great towns or their vicinity.

Such bodies as are interred alone, in the midst of a great quantity of humid earth, are totally destroyed by passing through the successive degrees of the ordinary putrefaction; and this destruction is more speedy, the warmer the temperature. But if these insulated bodies be dry and emaciated; if the place of deposition be likewise dry, and the locality and other circumstances such, that the earth, so far from receiving moisture from the atmosphere, becomes still more effectually parched by the solar rays;—the animal juices are volatilized and absorbed, the solids contract and harden, and a peculiar species of mummy is produced. But every circumstance is very different in the common burying-grounds. Heaped together almost in contact, the influence of external bodies affects them scarcely at all, and they become abandoned to a peculiar disorganization, which destroys their texture, and produces the new and most permanent state of combination here described. From various observations, it was found, that this fatty matter was capable of enduring in these burying-places for thirty or forty years, and is at length corroded and carried off by the aqueous putrid humidity which there abounds.

Among other interesting facts afforded by the chemical examination of this substance are the following from experiments by Fourcroy.

1. This substance is fused at a less degree of heat than that of boiling water, and may be puri-

fied by pressure through a cloth, which disengages a portion of fibrous and bony matter. 2. The process of destructive distillation by a very graduated heat was begun, but not completed on account of its tediousness, and the little promise of advantage it afforded. The products which came over were water charged with volatile alcali, a fat oil, concrete volatile alcali, and no elastic fluid during the time the operation was continued. 3. Fragments of the fatty matter exposed to the air during the hot and dry summer of 1786 became dry, brittle, and almost pulverulent at the surface. On a careful examination, certain portions were observed to be semitransparent, and more brittle than the rest. These possessed all the apparent properties of wax, and did not afford volatile alcali by distillation. 4. With water this fatty matter exhibited all the appearances of soap, and afforded a strong lather. The dried substance did not form the saponaceous combination with the same facility or perfection as that which was recent. About two-thirds of this dried matter separated from the water by cooling, and proved to be the semitransparent substance resembling wax. This was taken from the surface of the soapy liquor, which being then passed through the filter, left a white soft shining matter, which was fusible and combustible. 5. Attempts were made to ascertain the quantity of volatile alcali in this substance, by the application of lime, and of the fixed alcalies, but without sucess: for it was difficult to collect and appreciate the first portions which escaped, and likewise to disengage the last portions. The caustic volatile alcali, with the assistance of a gentle heat, dissolved the fatty matter, and the solution became perfectly clear and transparent at the boiling temperature of the mixture, which was at 185° F. 6. Sulphuric acid, of the specific gravity of 2.0, was poured upon six times its weight of the fatty matter, and mixed by agitation. Heat was produced, and a gas or effluvium of the most insupportable putrescence was emitted, which infected the air of an extensive laboratory for several days. Fourcroy says, that the smell cannot be described, but that it is one of the most horrid and repulsive that can be imagined. It did not, however, produce any indisposition either in himself or his assistants. By dilution with water, and the ordinary processes of evaporation and cooling, properly repeated, the sulphates of ammonia and of lime were obtained. A substance was separated from the liquor, which appeared to be the waxy matter, somewhat altered by the action of the acid. 7. The nitrous and muriatic acids were also applied, and afforded phenomena worthy of remark, but which for the sake of conciseness are here omitted. 8. Alcohol does not act on this matter at the ordinary temperature of the air. But by boiling it dissolves one-third of its own weight, which is almost totally separable by cooling as low as 55°. The alcohol, after this process, affords by evaporation a portion of that waxy matter which is separable by acids, and is therefore the only portion soluble in cold alcohol. The quantity of fatty matter operated on was 4 ounces, or 2304 grains, of which the boiling spirit took up the whole except 26 grains, which proved to be a mixture of 20 grains of ammoniacal soap, and 6 or 8 grains of the phosphates of soda and of lime. From this experiment, which was three times repeated with similar results, it appears that alcohol is well suited to afford an analysis of the fatty matter. It does not dissolve the neutral salts; when cold, it dissolves that portion of concrete animal oil from which the volatile alcali had flown off; and when heated, it dissolves the whole of the truly saponaceous matter, which is afterwards completely separated by cooling. And accordingly it was found, that a thin plate of the fatty matter, which had lost nearly the whole of its volatile alcali, by exposure to the air for three years, was almost dissolved by the cold alcohol.

The concrete oily or waxy substance obtained in these experiments constitutes the leading object of research, as being the peculiar substance with which the other well-known matters are combined. It separates spontaneously by the action of the air, as well as by that of acids. These last separate it in a state of greater purity, the less disposed the acid may be to operate in the way of combustion. It is requisite, therefore, for this purpose, that the fatty matter should be previously diffused in 12 times its weight of hot water; and the muriatic or acetous acid is preferable to the sulphuric or the nitrous. The colour of the waxy matter is grayish; and though exposure to the air, and also the action of the oxygenated muriatic acid did produce an apparent whiteness, it nevertheless disappeared by subsequent fusion. No method was discovered by which it could be permanently bleached.

The nature of this wax or fat is different from that of any other known substance of the like kind. When slowly cooled after fusion, its texture appears crystalline or shivery, like spermaceti; but a speedy cooling gives it a semitransparency resembling wax. Upon the whole, nevertheless, it seems to approach more nearly to the former than to the latter of these bodies. It has less smell than spermaceti, and melts at 127° F.; Dr. Bostock says 92°. Spermaceti requires 6° more of heat to fuse it, (according to Dr. Bostock 20°.) The spermaceti did not so speedily become brittle by cooling as the adipocire. One ounce of alcohol of the strength between 39 and 40 degrees of Baume's aerometer, dissolved when boiling hot 12 gros of this substance, but the same quantity in like circumstances dissolved only 30 or 36 grains of spermaceti. The separation of these matters was also remarkably different, the spermaceti being more speedily deposited, and in a much more regular and crystalline form. Ammonia dissolves with singular facility, and even in the cold, this concrete oil separated from the fatty matter; and by heat it forms a transparent solution, which is a true soap. But no excess of ammonia can produce such an effect with spermaceti.

Fourcroy concludes his memoir with some speculations on the change to which animal substances in peculiar circumstances are subject In the modern chemistry, soft animal matters are considered as a composition of the oxydes of hydrogen and carbonated azote, more complicated than those of vegetable matters, and therefore more incessantly tending to alteration. If then the carbon be conceived to unite with the oxygen, either of the water which is present, or of the other animal matters, and thus escape in large quantities in the form of carbonic acid gas, we shall perceive the reason why this conversion is attended with so great a loss of weight, namely, about nine-tenths of the whole. The azote, a principle so abundant in animal matters, will form ammonia by combining with the hydrogen; part of this will escape in the vaporous form, and the rest will remain fixed in the fatty matter. The residue of the animal matters deprived of a great part of their carbon, of their oxygen, and the whole of their azote, will consist of a much greater proportion of hydrogen, together with carbon and a minute quantity of oxygen. This, according to the theory of Fourcroy, constitutes the waxy matter, or adipocire, which, in combination with ammonia, forms the animal soap, into which the dead bodies are thus converted.

Muscular fibre, macerated in dilute nitric acid, and afterwards well washed in warm water, affords pure adipocire, of a light yellow colour, nearly of the consistence of tallow, of a homogeneous texture, and of course free from ammonia. This is the mode in which it is now commonly procured for chemical experiment.

Ambergris appears to contain adipocire in large quantity, rather more than half of it being of this substance.

Adipocire has been more recently examined by Chevreul. He found it composed of a small quantity of ammonia, potassa, and lime, united to much margarine, and to a very little of another fatty matter different from that. Weak muriatic acid seizes the three alcaline bases. On treating the residue with a solution of potassa, the margarine is precipitated in the form of a pearly substance, while the other fat remains dissolved. Fourcroy being of opinion that the fatty matter of animal carcasses, the substance of biliary calculi, and spermaceti, were nearly identical, gave them the same name of adipocire; but it appears from the researches of Chevreul that these substances are very different from each other.

In the Philosophical Transactions for 1813, there is a very interesting paper on the above subject by Sir E. Home and Mr. Brande. He adduces many curious facts to prove that adipocire is formed by an incipient and incomplete putrefaction. Mary Howard, aged 44, died on the 12th May 1790, and was buried in a grave ten feet deep at the east end of Shoreditch church-yard, ten feet to the east of the great common sewer, which runs from north to south, and has always a current of water in it, the usual level of which is eight feet below the level of the ground, and two feet above the level of the coffins in the graves. In August 1811, the body was taken up, with some others buried near it, for the purpose of building a vault, and the flesh in all of them was converted into adipocire or spermaceti. At the full and new moon the tide raises water into the graves, which at other times are dry. To explain the extraordinary quantities of fat or adipocire formed by animals of a certain intestinal construction, Sir E. observes, that the current of water which passes through their colon, while the loculated lateral parts are full of solid matter, places the solid contents in somewhat similar circumstances to dead bodies in the banks of a common sewer.

The circumstance of ambergris, which contains 60 per cent. of fat, being found in immense quantities in the lower intestines of the spermaceti whales, and never higher up than seven feet from the anus, is an undeniable proof of fat being formed in the intestines; and as ambergris is only met with in whales out of health, it is most probably collected there from the absorbents, under the influence of disease, not acting so as to take it into the constitution. In the human colon, solid masses of fat are sometimes met with in a diseased state of that canal. A description and analysis by Doctor Ure of a mass of ambergris, extracted in Perthshire from the rectum of a living woman, were published in a London Medical Journal in September, 1817. There is a case communicated by Dr. Babington, of fat formed in the intestines of a girl four and a half years old, and passing off by stool. Mr. Brande found, on the suggestion of Sir E. Home, that muscle digested in bile, is convertible into fat, at the temperature of about 100°. If the substance, however, pass rapidly into putrefaction, no fat is formed. Fæces voided by a gouty gentleman after six days' constipation, yielded, on infusion in water, a fatty film. This process of forming fat in the lower intestines by means of bile, throws considerable light upon the nourishment derived from clysters, a fact well ascertained, but which could not be explained. It also accounts for the wasting of the body, which so invariably attends all complaints of the lower bowels. It accounts too for all the varieties in the turns of the colon, which we meet with in so great a degree in different animals. This property of the bile explains likewise the formation of fatty concretions in the gall bladder so commonly met with, and which, from these experiments, appear to be produced by the action of the bile on the mucus secreted in the gall bladder; and it enables us to understand how want of the gall bladder in children, from mal-formation, is attended with excessive leanness, notwithstanding a great appetite, and leads to an early death. Fat thus appears to be formed in the intestines, and from thence received into the circulation, and deposited in almost every part of the body. And as there appears to be no direct channel by which any superabundance of it can be thrown out of the body, whenever its supply exceeds the consumption, its accumulation becomes a disease, and often a very distressing one.

ADI′POSE. (*Adiposus*; from *adeps*, fat.) Fatty; as adipose membrane, &c.

ADIPOSE MEMBRANE. *Membrana adiposa.* The fat collected in the cells of cellular membrane.

ADI′PSA. (From α, neg. and διψα, thirst. 1. So the Greeks called medicines, &c. which abate thirst.

2. Hippocrates applied this word to oxymel.

ADI′PSIA. (From α, neg. and διψα, thirst.) A want of thirst. A genus of disease in the class *locales*, and order *dysorexiæ* of Cullen's Nosology. It is mostly symptomatic of some disease of the brain.

ADI′PSOS. So called because it allays thirst.) 1. The Egyptian palm-tree, the fruit of which is said to be the *Myrobalans*, which quench thirst.

2. Also a name for liquorice.

ADI′RIGE. Ammoniacal salt.

ADGUTO′RIUM. (From *ad* and *juvo*, to help.) A name of the *humerus*, from its usefulness in lifting up the fore-arm.

ADJUVA′NTIA. Whatever assists in preventing or curing disease.

ADNATA TUNICA. *Albuginea oculi; Tunica albuginea oculi.* A membrane of the eye mostly confounded with the *conjunctiva.* It is, however, thus formed: five of the muscles which move the eye, take their origin from the bottom of the orbit, and the sixth arises from the edge of it; they are all inserted, by a tendinous expansion, into the anterior part of the *tunica sclerotica,* which expansion forms the adnata and gives the whiteness peculiar to the fore-part of the eye. It lies betwixt the *sclerotica* and *conjunctiva.*

ADNA′TUS. (From *adnescor*, to grow to.) A term applied to some parts which appear to grow to others: as *tunica adnata, stipulæ adnatæ, folium adnatum.*

A′DOC. Milk.

ADOLESCE′NTIA. See *Age.*

ADO′NION. (From Αδωνις, the youth from whose blood it was feigned to have sprung.) *Adonium.* See *Artemisia abrotanum.*

ADONIUM. See *Adonion.*

ADO′PTER. *Tubus intermedius.* A chemical vessel with two necks used to combine retorts to the cucurbits or matrasses in distillation, with retorts instead of receivers.

A'dor. A sort of corn, called also spelta.

A'dos. Forge water, or water in which red-hot iron is extinguished.

AD PONDUS OMNIUM. The weight of the whole. These words are inserted in pharmaceutical preparations, or prescriptions, when the last ingredient ought to weigh as much as all the others put together.

ADPRESSUS. Approximated. A term in botany, applied to branches of leaves when they rise in a direction nearly parallel to the stem, and are closely applied to them, as in the branches of the *Genista tinctoria* and leaves of the *Thlaspi campestris*.

Adra rhi'za. Blancard says the root of the Aristolochia is thus named.

Adra'chne. The strawberry bay-tree. A species of *Arbutus*.

A'dram. Fossil salt.

Adrara'gi. An Indian name for our garden-saffron.

ADROBO'LON. (From *αδρος*, large, and *βωλος*, a globe, bole, or mass.) Indian bdellium, which is coarser than the Arabian. See *Bdellium*.

ADSCENDENS. See *Ascendens*.

ADSTRICTION. Costiveness.

ADSTRINGENT. See *Astringent*.

ADUSTION. *Adustio*. 1. An inflammation about the brain, and its membranes, with a hollowness of the eyes, a pale colour, and a dry body; obsolete.

2. In surgery adustion signifies the same as cauter isation, and means the application of any substance to the animal body, which acts like fire. The ancient surgeons, especially the Arabians, were remarkably fond of having recourse to adustion in local diseases; but the use of actual heat is very rarely admitted by the moderns.

ADVENTITIOUS. (*Adventitius*; from *advenio*, to come to.) Any thing that accidentally, and not in the common course of natural causes, happens to make a part of another. Something accruing or befalling a person or thing from without. It is used in medicine in opposition to hereditary; as when diseases may be transmitted from the parent and also acquired, as is the case with gout and scrofula. They are sometimes hereditary, and very often adventitious.

ADVERSIFO'LIA. (From *adversus*, opposite, and *folium*, a leaf.) A plant with alternate leaves.

Adversifo'liæ plantæ. 1. Plants the leaves of which stand opposite to each other on the same stem or branch.

2. The name of a class in Sauvages' *Methodus Foliorum*. Valerian, teasel, honey-suckle, &c. are examples.

ADVERSUS. Opposite. Applied in natural history to parts which stand opposite to each other; as *plantæ adversifoliæ*, the leaves standing opposite to each other on the same stem, as in valerian, teasel, honey-suckle, &c.

ADYNA'MIA. (*Adynamia*, *æ*, f. *Αδυναμια*; from *α*, priv. and *δυναμις*, power.) A defect of vital power.

Adyna'miæ. (The plural of *Adynamia*.) The second order of the class *neuroses* of Cullen's Nosology: it comprehends *syncope*, *dyspepsia*, *hypochondriasis*, and *chlorosis*.

Ady'namon. (From *α*, neg. and *δυναμις*, strength.) *Adynamum*. Among ancient physicians, it signified a kind of weak factitious wine, prepared from must, boiled down with water; to be given to patients to whom pure or genuine wine might be hurtful.

Adynamum. See *Adynamon*.

ÆDOI'A. (From *αιδως*, modesty; or from *α*, neg. and *αδω*, to see, as not being decent to the sight.) The pudenda, or parts of generation.

ÆDOPSO'PHIA. (From *αιδοια*, *pudenda*; and *ψοφεω*, to break wind.) A term used by Sauvages and Sagar, to signify a flatus from the bladder, or from the womb, making its escape through the vagina.

ÆDOPTO'SIS. (*Ædoptosis*; from *αιδοιον*, the groin: pl. *αιδοια*, *pudenda*; and *πτωσις*, a falling down.) Genital prolapsi. The name of a genus of diseases in Good's Nosology.

ÆGAGRO'PILUS. (From *αιγαγρος*, a wild goat, and *pila*, a ball.) *Ægagropila*.

1. A ball found in the stomach of deer, goats, hogs, horned cattle, as cows, &c. It consists of hairs which they have swallowed from licking themselves. They are of different degrees of hardness, but have no medicinal virtues. Some rank these balls among the *Bezoars*. Hieronymus Velschius wrote a treatise on the virtues of this.

2. A species of conferva found in Wallenfenmoor, from its resembling these concretions, is also so named.

Æ'GIAS. A white speck on the pupil of the eye, which occasions a dimness of sight.

ÆGI'DES. *Aglia*. A disorder of the eyes mentioned by Hippocrates. Foesius thinks the disease consists of small cicatrices in the eye, caused by an afflux of corrosive humours upon the part. But in one passage of Hippocrates, Foësius says it signifies small white concretions of humours which stick upon the pupil, and obscure the sight.

ÆGI'DION. A collyrium or ointment for inflammations and defluxions of the eyes.

Æ'GILOPS. 1. The same as *Ægylops*.

2. Wild fescue grass, so called from its supposed virtue in curing the disorder named Ægylops. It is a species of *Bromus* in the Linnean system.

ÆGINE'TA, Paulus. A celebrated surgeon of the island of Ægina, from which he derived his name. He is placed by Le Clerc in the fourth century; by others in the seventh. He was eminently skilled in his profession, and his works are frequently cited by Fabricius ab Aquapendente. He is the first author that notices the cathartic quality of rhubarb. He begins his book with the description of the diseases of women; and is said to be the first that deserves the appellation of a man midwife.

Ægine'tia. Malabrian broom rape. A species of *Orobanche*.

Æ'GIS. A film on the eye.

ÆGO'CERAS. (From *αιξ*, a goat, and *κερας*, a horn; so called, because the pods were supposed to resemble the horns of a goat.) Fœnugreek. See *Trigonella Fænumgræcum*.

ÆGO'LETHRON. (From *αιξ*, a goat, and *ολεθρος*, destruction: so named from the opinion of its being poisonous to goats.) Tournefort says it is the *Chamærododendron*, now the *Azelæa pontica* of Linnæus.

ÆGO'NYCHON. (From *αιξ*, a goat, and *ονυξ*, a hoof; because of the hardness of the seed.) See *Lithospermum officinale*.

ÆGOPO'DIUM. (*Ægopodium*, *i*, n.; from *αιξ*, a goat, and *πους*, a foot: from its supposed resemblance to a goat's foot.) A genus of plants in the Linnæan system. Class, *Pentandria*; Order, *Digynia*. Goatweed. The following species was formerly much esteemed.

ÆGOPODIUM PODAGRARIA. Goatweed. This plant is sedative, and was formerly applied to mitigate pains of gout, and to relieve piles, but not now employed. In its earlier state it is tender and esculent.

ÆGOPROSO'PON. (From αιξ, a goat, and ὦροσωπον, a face: so called because goats are subject to defects in the eyes, or from having in it some ingredients named after the goat.) A name of a lotion for the eyes, when inflamed.

Æ'GYLOPS. (*Ægylops, opis*, m.; from αιξ, a goat, and ωψ, an eye.) *Anchilops.* A disease so named from the supposition that goats were very subject to it. The term means a sore just under the inner angle of the eye. The best modern surgeons seem to consider the ægylops only as a stage of the fistula lachrymalis. Paulus Ægineta calls it anchilops, before it bursts, and ægylops after. When the skin covering the lachrymal sac has been for some time inflamed, or subject to frequent returning inflammations, it most commonly happens that the puncta lachrymalia are affected by it; and the fluid, not having an opportunity of passing off by them, distends the inflamed skin, so that at last it becomes sloughy, and bursts externally. This is that state of the disease which is called perfect *aigylops*, or *ægylops.*

ÆGY'PTIA MUSCATA. See *Hibiscus abelmoschus.*

ÆGYPTI'ACUM. A name given to different unguents of the detergent or corrosive kind. We meet with a black, a red, a white, a simple, a compound, and a magistral ægyptiacum. The simple ægyptiacum, which is that usually found in our shops, is a composition of verdigris, vinegar, and honey, boiled to a consistence. It is usually supposed to take its name from its dark colour, wherein it resembles that of the natives of Egypt. It is improperly called an unguent, as there is no oil, or rather fat, in it.

ÆGY'PTIUM PHARMACUM AD AURES. Aëtius speaks of this as excellent for deterging fœtid ulcers of the ears, which he says it cures, though the patient were born with them.

AEI'GLUCES. (From αει, always, and γλυκυς, sweet.) A sweetish wine, or must.

AEIPATHEI'A. (From αει, always, and παθος, a disease. Diseases of long duration.

ÆNEA. (From *æs*, brass, so called because it was formerly made of brass.) A catheter.

Æ'ON. The spinal marrow.

ÆONE'SIS. A washing, or sprinkling of the whole body.

ÆO'NION. The common house leek. See *Sempervivum tectorum.*

ÆO'RA. (From αιωρεω, to lift up, to suspend on high.) Exercise without muscular action; as swinging. A species of exercise used by the ancients, and of which Aëtius gives the following account. Gestation, while it exercises the body, the body seems to be at rest. Of this motion there are several kinds. First, swinging in a hammock, which, at the decline of a fever, is beneficial. Secondly, being carried in a litter, in which the patient either sits or lies along. It is useful when the gout, stone, or such other disorder attends, as does not admit of violent motions. Thirdly, riding in a chariot, which is of service in most chronical disorders; especially before the more violent exercises can be admitted. Fourthly, sailing in a ship or boat. This produces various effects, according to the different agitation of the waters, and, in many tedious chronical disorders, is efficacious beyond what is observed from the most skilful administration of drugs. These are instances of a passive exercise.

Æ'POS. An excrescence, or protuberance.

ÆQUA'LIS. Equal. Applied by botanists to distinguish length; as, *filimenta æqualia; pedunculi æquales*, &c.

Æ'QUE. Equally. The same as *ana.*

ÆQUIVALVIS. *Æquivalve.* A botanical term, implying, composed of equal valves.

A'ER. (*Aer, eris*, m.; from αηρ.) The fluid which surrounds the globe. See *Air* and *Atmosphere.*

Æ'RA. Darnel, or lolium.

Ærated alkaline water. Water impregnated with carbonic acid.

ÆRIAL. Belonging to air.

Ærial acid. See *Carbonic acid.*

Ærial plants. Those plants are so called which, after a certain time, do not require that their roots should be fixed to any spot in order to maintain their life, which they do by absorption from the atmosphere. Such are a curious tropical tribe of plants called cacti, the epidendrum, flos æris, and the ficus australis.

ÆRI'TIS. The *Anagallis*, or pimpernell.

ÆROLITE. A meteoric stone.

AEROLO'GICE. See *Aerology.*

AEROLO'GY. (*Aerologia, æ*, f.; from αηρ, the air, and λογος, a discourse.) *Aerologice.* That part of medicine which treats of the nature and properties of air.

AERO'MELI. Honey dew; also a name for manna.

ÆROMETER. An instrument for making the necessary corrections in pneumatic experiments to ascertain the mean bulk of the gases.

AEROPHO'BIA. Fear of air or wind.

1. Said to be a symptom of phrenitis.

2. A name of *Hydrophobia.*

AERO'PHOBUS. (From αηρ, air, and φοβος, fear.) According to Cœlius Aurelianus, some phrenctic patients are afraid of a lucid, and others of an obscure air: and these he calls *aerophobi.*

AERO'SIS. The aerial vital spirit of the ancients.

ÆROSTATION. *Ærostatio.* A name commonly, but not very correctly, given to the art of raising heavy bodies into the atmosphere, by buoyancy of heated air, or gases of small specific gravity, enclosed in a bag, which from being usually of a spherical form, is called a balloon.

ÆRO'SUS LAPIS. So Pliny calls the *Lapis calaminaris*, upon the supposition that it was a copper ore.

ÆRU'CA. Verdigris.

ÆRU'GO. (*Ærugo, ginis*, f.; from *æs*, copper.) 1. The rust of any metal, particularly of copper.

2. Verdigris. See *Verdigris.*

ÆRUGO ÆRIS. Rusts of copper or verdigris. See *Verdigris.*

ÆRUGO PRÆPARA'TA. See *Verdigris.*

ÆS. Brass.

ÆSCHROMYTHE'SIS. The obscene language of the delirious.

ÆSCULA'PIUS, said to be the son of Apollo, by the nymph Coronis, born at Epidaurus, and educated by Chiron, who taught him to cure the most dangerous diseases, and even raise the dead; worshipped by the ancients as the god of medicine. His history is so involved in fable, that it is useless to trace it minutely. His two sons, Machaon and Podalirius, who ruled over a small city in Thessaly, after his death accompanied the Greeks to the siege of Troy: but Homer speaks merely of their skill in the treatment of wounds; and divine honours were not paid to their father till a latter period. In the temples raised to him, votive tablets were hung up, on which were recorded the diseases cured, as they imagined, by his assistance.

ÆSCULUS. (*Æsculus, i,* m.; from *esca,* food.) The name of a genus of plants in the Linnæan system. Class, *Heptandria;* Order, *Monogynia.* Horse-chesnut.

ÆSCULUS HIPPOCASTANUM. The systematic name for the common horse-chesnut tree. *Castanea equina, pavina. Æsculus—foliolis septenis* of Linnæus. The fruit of this tree, when dried and powdered, is recommended as an errhine. The bark is highly esteemed on the Continent as a febrifuge; and is, by some, considered as being superior in quality to the Peruvian bark. The bark intended for medical use is to be taken from those branches which are neither very young nor very old, and to be exhibited under similar forms and doses, as directed with respect to the Peruvian bark. It rarely disagrees with the stomach; but its astringent effects generally require the occasional administration of a laxative. During the late scarcity of grain, some attempts were made to obtain starch from the horse-chesnut, and not without success.

ÆSECA'VUM. Brass.

ÆSTA'TES. Freckles in the face; sunburnings.

ÆSTHE'TICA. (From *αισθανομαι,* to feel, or perceive.) Diseases affecting the sensation. The name of an order of diseases in Good's Nosology. See *Nosology.*

ÆSTIV'ALIS. (From *æstas,* summer.) Æstival; belonging to summer. Diseases of animals and plants which appear in the summer.

ÆSTIVALES PLANTÆ. Plants which flower in summer. A division according to the seasons of the year.

ÆSTIVA'TIO. Æstivation; the action of the summer, or its influence on things.

ÆSTPHARA. Incineration, or burning of the flesh, or any other part of the body.

ÆSTUA'RIUM. A stove for conveying heat to all parts of the body at once. A kind of vapour bath. Ambrose Parey calls an instrument thus, which he describes for conveying heat to any particular part. Palmarius, De Morbis Contagiosis, gives a contrivance under this name, for sweating the whole body.

ÆSTUA'TIO. The boiling up, or rather the fermenting of liquors when mixed.

Æ'STUS. *Æstus, ûs,* m.; from the Hebrew *esh,* heat. Heat; applied to the feeling merely of heat, and sometimes to that of inflammation in which there is heat and redness.

ÆSTUS VOLATICUS. 1. Sudden heat, or scorching, which soon goes off, but which for a time reddens the part.

2. According to Vogel, synonymous with phlogosis.

3. *Erythema volaticum* of Sauvages.

ÆTAS. See *Age.*

ÆTAS CREPITA. See *Age.*

ÆTAS VIRILIS. See *Age.*

Æ'THER. (*Æther, eris,* m.; from *αιθηρ*: a supposed fine subtile fluid. Æther. A volatile liquor, obtained by distillation, from a mixture of alcohol and a concentrated acid.

The medical properties of æther, when taken internally, are antispasmodic, cordial, and stimulant. Against nervous and typhoid fevers, all nervous diseases, but especially tetanic affections, soporose diseases from debility, asthma, palsy, spasmodic colic, hysteria, &c. it always enjoys some share of reputation. Regular practitioners seldom give so much as empirics, who sometimes venture upon large quantities, with incredible benefit. Applied externally, it is of service in the headache, toothache, and other painful affections. Thus employed, it is capable of producing two very opposite effects, according to its management; for, if it be prevented from evaporating, by covering the place to which it is applied closely with the hand, it proves a powerful stimulant and rubefacient, and excites a sensation of burning heat, as is the case with solutions of camphor in alkohol, or turpentine. In this way it is frequently used for removing pains in the head or teeth. On the contrary, if it be dropped on any part of the body, exposed freely to the air, its rapid evaporation produces an intense degree of cold; and, as this is attended with a proportional diminution of bulk in the part, applied in this way, it has frequently contributed to the reduction of the intestine, in cases of strangulated hernia.

ÆTHER RECTIFICATUS. *Æther vitriolicus.* Rectified æther. Take of sulphuric æther, fourteen fluid ounces. Fused potash, half an ounce. Distilled water, eleven fluid ounces.

First dissolve the potash in two ounces of the water, and add thereto the æther, shaking them well together, until they are mixed. Next, at a temperature of about 200 degrees, distil over twelve fluid ounces of rectified æther, from a large retort into a cooled receiver. Then shake the distilled æther well with nine fluid ounces of water, and set the liquor by, so that the water may subside. Lastly, pour off the supernatant rectified æther, and keep it in a well-stopped bottle.

Sulphuric æther is impregnated with some sulphureous acid, as is evident in the smell, and with some ætherial oil: and these require a second process to separate them. Potash unites to the acid, and requires to be added in a state of solution, and in sufficient quantities, for the purpose of neutralising it; and it also forms a soap with the oil. It is advantageous also to use a less quantity of water than exists in the ordinary solution of potash; and therefore the above directions are adopted in the last London Pharmacopœia. For its virtues, see *Æther.*

ÆTHER SULPHURICUS. *Naphtha vitrioli; Æther vitriolicus.* Sulphuric æther. Take of rectified spirit, sulphuric acid, of each, by weight, a pound and a half. Pour the spirit into a glass retort, then gradually add to it the acid, shaking it after each addition, and taking care that their temperature, during the mixture, may not exceed 120 degrees. Place the retort very cautiously into a sand bath, previously heated to 200 degrees, so that the liquor may boil as speedily as possible, and the æther may pass over into a tubulated receiver, to the tubulure of which another receiver is applied, and kept cold by immersion in ice, or water. Continue the distillation until a heavier part also begins to pass over, and appear under the æther in the bottom of the receiver. To the liquor which remains in the retort, pour twelve fluid ounces more of rectified spirit, and repeat the distillation in the same manner.

It is mostly employed as an excitant, nervine, antispasmodic, and diuretic, in cases of spasms, cardialgia, enteralgia, fevers, hysteria, cephalagia, and spasmodic asthma. The dose is from min. xx to ʒij. Externally, it cures toothache, and violent pains in the head. See *Æther.*

ÆTHER VITRIOLICUS. See *Æther sulphuricus* and *Æther rectificatus.*

ÆTHE'REA HERBA. The plant formerly so called is supposed to be the Eryngium.

ÆTHERIAL OIL. See *Oleum Ætherium.*

Æ'THIOPS. A term applied formerly to several preparations, because of a black colour, like the skin of an Æthiopian.

ÆTHIOPS ANTIMONIA'LIS. A preparation of

antimony and mercury, once in high repute, and still employed by some practitioners in cutaneous diseases. A few grains are to be given at first, and the quantity increased as the stomach can bear it.

ÆTHIOPS MARTIALIS. A preparation of iron, formerly in repute, but now neglected.

Æthiops mineral. The substance heretofore known by this name, is called by the London College, *Hydrargyri sulphuretum nigrum.*

ÆTHMOID. See *Ethmoid.*

Æthmoid Artery. See *Ethmoid Artery.*

Æthmoid Bone. See *Ethmoid Bone.*

Æ′THNA. A chemical furnace.

Æ′THOCES. *Ætholices.* Superficial pustules in the skin, raised by heat; as boils; fiery pustules.

ÆTHU′SA. (*Æthusa, æ,* f.; from αιθουσα, beggarly.) The name of a genus of plants of the Linnæan system. Class, *Pentandria;* Order, *Digynia.*

ÆTHUSA MEUM. The systematic name of the *meum* of the Pharmacopœias. Called also *Meum athamanticum; Meu; Spignel; Baldmoney.* The root of this plant is recommended as a carminative, stomachic, and for attenuating viscid humours, and appears to be nearly of the same nature as lovage, differing in its smell, being rather more agreeable, somewhat like that of parsnips, but stronger, and being in its taste less sweet, and more warm, or acrid.

ÆTHYA. A mortar.

Æ′TIOI PHLEBES. Eagle veins. The veins which pass through the temples to the head, were so called formerly by Rufus Ephesius.

ÆTIOLOGY. (*Ætiologia, æ,* f.; αιτιολογια: from αιʇια, a cause, and λογος, a discourse.) The doctrine of the causes of diseases.

ÆTITES. Eagle stone. A stone formed of oxyde of iron, containing in its cavity some concretion which rattles on shaking the stone. Eagles were said to carry them to their nest, whence their name: and superstition formerly ascribed wonderful virtues to them.

AE′TIUS. A physician, called also *Amidenus,* from the place of his birth. He flourished at Alexandria, about the end of the fifth century, and left sixteen books, divided into four *tetrabiblia,* on the practice of physic and surgery, principally collected from Galen and other early writers, but with some original observations. He appears very partial to the use of the cautery, both actual and potential, especially in palsy; which plan of treatment Mr. Pott revived in paraphlegia; and it has since often been adopted with success. Aëtius is the earliest writer who ascribed medical efficacy to the external use of the magnet, particularly in gout and convulsions; but rather on the report of others, than as what he had personally experienced.

ÆTO′CION. *Ætolium.* The granum cnidium. See *Daphne mezereon.*

ÆTOLIUM. See *Ætocion.*

ÆTO′NYCHUM. See *Lithospermum.*

AFFECTION. (*Affectio, onis,* f. This is expressed in Greek by ϖαθος: hence *pathema, passio.*) Any existing disorder of the whole body, or a part of it; as hysterics, leprosy, &c. Thus, by adding a descriptive epithet to the term affection, most distempers may be expressed. And hence we say febrile affection, cutaneous affection, &c. using the word affection synonymously with disease.

AFFINITY. (*Affinitas, atis,* f.; a proximity of relationship.) The term affinity is used indifferently with attraction. See *Attraction.*

AFFINITY OF AGGREGATION. See *Attraction.*

AFFINITY, APPROPRIATE. See *Affinity, intermediate.*

AFFINITY OF COMPOSITION. See *Attraction.*

AFFINITY, COMPOUND. When three or more bodies, on account of their mutual affinity, unite and form one homogeneous body, then the affinity is termed compound affinity or attraction: thus, if to a solution of sugar and water be added spirits of wine, these three bodies will form an homogeneous liquid by compound affinity.

AFFINITY, DIVELLENT. See *Affinity, quiescent.*

AFFINITY, DOUBLE. *Double elective attraction.* When two bodies, each consisting of two elementary parts, come into contact, and are decomposed, so that their elements become reciprocally united, and produce two new compound bodies, the decomposition is then termed decomposition by double affinity: thus, if we add common salt, which consists of muriatic acid and soda, to nitrate of silver, which is composed of nitric acid and oxyde of silver, these two bodies will be decompounded; for the nitric acid unites with the soda, and the oxyde of silver with the muriatic acid, and thus may be obtained two new bodies. The common salt and nitrate of silver therefore mutually decompose each other by what is called double affinity.

AFFINITY, INTERMEDIATE. *Appropriate affinity.* Affinity of an intermedium is, when two substances of different kinds, that show to one another no component affinity, do, by the assistance of a third, combine, and unite into an homogeneous whole: thus, oil and water are substances of different kinds, which, by means of alcali, combine and unite into a homogeneous substance: hence the theory of lixiviums, of washing, &c. See *Attraction.*

AFFINITY, QUIESCENT. Mr. Kirwan employs the term *Quiescent affinity* to mark that, by virtue of which, the principles of each compound, decomposed by double affinity, adhere to each other; and *Divellent affinity,* to distinguish that by which the principles of one body unite and change order with those of the other: thus, sulphate of potash is not completely decomposed by the nitric acid or by lime, when either of these principles is separately presented; but if the nitric acid be combined with lime, this nitrate of lime will decompose the sulphate of potash. In this last case, the affinity of the sulphuric acid with the alcali is weakened by its affinity to the lime. This acid, therefore, is subject to two affinities, the one which retains it to the alcali, called *quiescent,* and the other which attracts it towards the lime, called *divellent* affinity.

AFFINITY, RECIPROCAL. When a compound of two bodies is decomposed by a third, the separated principle being in its turn capable of decomposing the new combination: thus, ammonia and magnesia will separate each other from muriatic acid.

AFFINITY, SIMPLE. *Single elective attraction.* If a body, consisting of two component parts, be decomposed on the approach of a third, which has a greater affinity with one of those component parts than they have for each other, then the decomposition is termed decomposition by *simple* affinity: for instance, if pure potash be added to a combination of nitric acid and lime, the union which existed between these two bodies will cease, because the potash combines with the nitric acid, and the lime, being disengaged, is precipitated. The reason is, that the nitric acid has a greater affinity for the pure potash than for the lime, therefore it deserts the lime, to combine with the potash. When two bodies only enter into chemical union, the affinity, which was the cause of it, is also termed *simple* or *single elective* attraction; thus the solution of sugar in water is produced by simple affinity, because there are but two bodies.

A'FFION. An Arabic name for opium.

A'FFIUM. An Arabic name for opium.

AFFLA'TUS. (From *ad* and *flare*, to blow.) A vapour or blast. A species of erysipelas, which attacks people suddenly, so named upon the erroneous supposition that it was produced by some unwholesome wind blowing on the part.

AFFUSION. (*Affusio*; from *ad*, and *fundo*, to pour upon.) Pouring a liquor upon something. The affusion of cold water, or pouring two or three quarts on the patient's head and body, is sometimes practised by physicians, but lately introduced by Dr. Currie, of Liverpool, in the treatment of typhus fever, and which appears to possess an uniformity of success, which we look for in vain in almost any other branch of medical practice. The remedy consists merely in placing the patient in a bathing-tub, or other convenient vessel, and pouring a pailful of cold water upon his body; after which he is wiped dry, and again put to bed. It should be noted,

First, That it is the *low contagious fever* in which the cold affusion is to be employed: the first symptoms of which are a dull head-ache, with restlessness and shivering; pains in the back, and all over the body, the tongue foul, with great prostration of strength; the head-ache becoming more acute, the heat of the body, by the thermometer, 102° to 105°, or more; general restlessness, increasing to delirium, particularly in the night.

Secondly, That it is *in the early stage of the disease* we must employ the remedy; and generally *in the state of the greatest heat and exacerbation.*

Thirdly, It is *affusion*, not *immersion*, that must be employed.

Since the first publication of Dr. Currie's work, the practice of affusion has been extended throughout England; and its efficacy has been established in some stages of the disease, from which the author had originally proscribed the practice of it. One of the cautionary injunctions which had been given for the affusion of cold water in fever, was, *never to employ it in cases where the patient had a sense of chilliness upon him*, even if the thermometer, applied to the trunk of the body, indicated a preternatural degree of heat. In his last edition of Reports, however, Dr. Currie has given the particulars of a case of this kind, in which the cold affusion was so managed as to produce a successful event.

In fevers *arising from*, or *accompanied by, topical inflammation*, his experience does not justify the use of cold affusion; though, in a great variety of these cases, the warm affusion may be used with advantage. "And," says, he, "though I have used the cold affusion in some instances, so late as the twelfth or fourteenth day of contagious fever, with safety and success, yet it can only be employed, at this advanced period, in the instances in which the heat keeps up steadily above the natural standard, and the respiration continues free. In such cases, I have seen it appease agitation and restlessness, dissipate delirium, and, as it were, snatch the patient from impending dissolution. But it is in the *early stages* of fever (let me again repeat) that it ought always to be employed, if possible; and where, without any regard to the heat of the patient, it is had recourse to in the last stage of fever, after every other remedy has failed, and the case appears desperate, (of which I have heard several instance,) can it appear surprising that the issue should sometimes be unfavourable?"

Numerous communications from various practitioners, in the West and East Indies, in Egypt and America, also show the efficacy of affusion in the raging fevers of hot countries.

AFORA. (From *α*, priv. and *fores*, a door.) Having a door or valve: applied to plants, the seed vessel of which is not furnished with a valvule.

AFTER-BIRTH. See *Placenta.*

A'GA CRETENSIUM. The small Spanish milk-thistle.

AGALACTA'TIO. See *Agalactia.*

AGALA'CTIA. (Αγαλακτια; from *α*, priv. and γαλα, milk.) *Agalaxis; Agalactio; Agalactatio.* A defect of milk in childbirth.

AGALA'CTOS. (From *α*, priv. and γαλα, milk.) An epithet given to women who have no milk when they lie in.

AGALA'XIS. See *Agalactia.*

AGALLOCHUM. See *Lignum aloes.*

AGALLOCHUM VERUM. See *Lignum aloes.*

AGA'LLUGE. See *Lignum aloes.*

AGALLUGUM. See *Lignum aloes.*

AGALMATOLITE. See *Figurestone.*

AGARIC. See *Agaricus.*

AGARICOI'DES. (From αγαρικος, the agaric, and ειδος, resemblance.) A species of fungus like the agaric.

AGA'RICUS. (*Agaricus, i. m.* αγαρικος: from *Agaria*, a town in Asia; or from *Agarus*, a river in Sarmatia, now Malowouda.) Agaric. The name of a genus of plants in the Linnæan system. Class, *Cryptogamia;* Order, *Fungi.* The plants of this genus appear to approach nearer to the nature of animal matter than any other productions of the vegetable kingdom, as, beside hydrogen, oxygen, and carbon, they contain a considerable portion of nitrogen, and yield ammonia by distillation. Prof. Proust has likewise discovered in them the benzoic acid, and phosphate of lime.

The mushrooms, remarkable for the quickness of their growth and decay, as well as for the fœtor attending their spontaneous decomposition, were unaccountably neglected by analytical chemists, though capable of rewarding their trouble, as is evinced by the recent investigations and discoveries of Messrs. Vauquelin and Braconnot. The insoluble fungous portion of the mushroom, though it resembles woody fibre in some respects, yet being less soluble than it in alcalies, and yielding a nutritive food, is evidently a peculiar product, to which accordingly the name of *fungin* has been given. Two new vegetable acids, the boletic and fungic, were also fruits of these researches.

The six following species have been submitted to chemical analysis; the results are affixed to each. 1. *Agaricus campestris*, an ordinary article of food, analysed by Vauquelin, gave the following constituents: 1. Adipocire. On expressing the juice of the agaric, and subjecting the remainder to the action of boiling alkohol, a fatty matter is extracted, which falls down in white flakes as the alkohol cools. It has a dirty white colour; a fatty feel, like spermaceti; and, exposed to heat, soon melts, and then exhales the odour of grease. 2. An oily matter. 3. Vegetable albumen. 4. The sugar of mushrooms. 5. An animal matter soluble in water and alkohol: on being heated, it evolves the odour of roasting meat, like osmazome. 6. An animal matter not soluble in alkohol. 7. Fungin. 8. Acetate of potash.

2. *Agaricus volvaceus* afforded Braconnot

fungin, gelatin, vegetable albumen, much phosphate of potash, some acetate of potash, sugar of mushrooms, a brown oil, adipocire, wax, a very fugacious deleterious matter, uncombined acid, supposed to be the acetic, benzoic acid, muriate of potash, and a deal of water; in all 14 ingredients.

3. *Agaricus acris*, or *piperatus*, was found by Braconnot, after a minute analysis, to contain nearly the same ingredients as the preceding, without the wax and benzoic acid, but with more adipocire.

4. *Agaricus stypticus.* From twenty parts of this Braconnot obtained of resin and adipocire 1.8, fungin 16.7, of an unknown gelatinous substance, a potash salt, and a fugacious acrid principle 1.5.

5. *Agaricus bulbosus*, was examined by Vauquelin, who found the following constituents: an animal matter insoluble in alkohol; osmazone; a soft fatty matter of a yellow colour and acrid taste; an acid salt, (not a phosphate.) The insoluble substance of the agaric yielded an acid by distillation.

6. *Agaricus theogolus.* In this, Vauquelin found sugar of mushrooms; osmazone; a bitter acrid fatty matter; an animal matter not soluble in alkohol; a salt containing a vegetable acid.

Agaricus albus. See *Boletus laricis.*

Agaricus campestris. There are several species of the agaric, which go by the term mushroom; as the *Agaricus chantarellus, deliciosus, violaceus*, &c.; but that which is eaten in this country is the *Agaricus campestris* of Linnæus. Similar to it in quality is the champignon, or *Agaricus pratensis.* Broiled with salt and pepper, or stewed with cream and some aromatic, they are extremely delicious, and, if not eaten to excess, salubrious. Great care should be taken to ascertain that they are the true fungus, and not those of a poisonous nature. Catchup is made by throwing salt on mushrooms, which causes them to part with their juice.

Agaricus chantarellus. A species of fungus, esteemed a delicacy by the French. Broiled with salt and pepper, it has much the flavour of a roasted cockle.

Agaricus chirurgorum. See *Boletus igniarius.*

Agaricus cinnamomeus. Brown mushroom. This species of agaric is of a pleasant smell. When broiled, it gives a good flavour.

Agaricus deliciosus. This fungus, well seasoned, and then broiled, has the exact flavour of a roasted muscle. It is in season in September.

Agaricus mineralis. A mineral; the mountain milk, or mountain meal, of the Germans. It is one of the purest of the native carbonates of lime, found chiefly in the clefts of rocks, and at the bottom of some lakes, in a loose or semi-indurated form. It has been used internally in hæmorrhages, strangury, gravel, and dysenteries; and externally as an application to old ulcers, and weak and watery eyes.

Agaricus muscarius. Bug Agaric; so called from its known virtue in destroying bugs. This reddish fungus is the *Agaricus—stipitatus, lamellis dimidiatis solitarus, stipite volvato, apice dilatato, basi ovato*, of Linnæus. It is not much known in this country. Haller relates that six persons of Lithuania perished at one time, by eating this kind of mushroom; and that in others it has caused delirium. The following account from Orfila, of the effects of this species in the animal economy, is interesting. Several French soldiers ate, at two leagues from Polosck, in Russia, mushrooms of the above kind. Four of them, of a robust constitution, who conceived themselves proof against the consequences under which their feebler companions were beginning to suffer, refused obstinately to take an emetic. In the evening, the following symptoms appeared. Anxiety, sense of suffocation, ardent thirst, intense griping pains, a small and irregular pulse, universal cold sweats, changed expression of countenance, violet tint of the nose and lips, general trembling, fœtid stools. These symptoms becoming worse, they were carried to the hospital. Coldness and livid colour of the limbs, a dreadful delirium, and acute pains, accompanied them to the last moment. One of them sunk a few hours after his admission into the hospital; the three others had the same fate in the course of the night. On opening their dead bodies, the stomach and intestines displayed large spots of inflammation and gangrene; and putrefaction seemed advancing very rapidly. It is employed externally to strumous phagedenic, and fistulous ulcers, as an escharotic.

Agaricus piperatus. The plant thus named by Linnæus, is the pepper mushroom; also called pepper agaric. It is the *Fungus piperatus albus, lacteo-succo turgens* of Ray. *Fungus albus acris.* When freely taken, fatal consequences are related by several writers to have been the result. When this vegetable has even lost its acrid juice by drying, its caustic quality still remains.

Agaricus pratensis. The champignon of Hudson's Flora Anglica. This plant has but little smell, and is rather dry, yet when broiled and stewed, communicates a good flavour.

Agaricus violaceus. Violet mushroom. This fungus requires much broiling, but when sufficiently done and seasoned, it is as delicious as an oyster. Hudson's *bulbosus* is only a variety of this.

AGATE. A mineral found chiefly in Siberia and Saxony, which consists of calcedony blended with variable proportions of jasper, amethyst, quartz, opal, heliotrope, and carnelion.

AGE. *Ætas.* The ancients reckoned six stages of life.

1. *Pueritia*, childhood, which is to the fifth year of our *age.*

2. *Adolescentia*, youth, reckoned to the eighteenth, and youth properly so called, to the twenty-fifth year.

3. *Juventus*, reckoned from the twenty-fifth to the thirty-fifth year.

4. *Virilis ætas*, manhood, from the thirty-fifth to the fiftieth year.

5. *Senectus*, old *age*, from fifty to sixty.

6. *Crepita ætas*, decrepid age, which ends in death.

AGENE'SIA. (Αγενησια; from α, neg. γεννάω, or γινομαι, to beget.) Male sterility, or impotency in man. A term employed by Vogel and Good. See *Nosology.*

A'GER. (*Ager, gri.* m.; from αγρος.) The common earth or soil.

Ager naturæ. The womb.

AGE'RATUM. (Αγηρατον; from α, priv. and γηρας, *senectus*: never old, ever green; because its flowers preserve their beauty a long time.) See *Achillæa ageratum.*

Agera'tus lapis. (*Ageratus*, common.) A stone used by cobblers.

A'GES. (From αγης, wicked; so called because it is generally the instrument of wicked acts.) The palm of the hand.

AGEU'STIA. (From α, neg. and γευομαι, *gusto*, to taste.) *Agheustia; Apogeustia; Apo-*

geusis. A defect or loss of taste. A genus of disease in the class *locales*, and order *dysæsthesiæ* of Cullen. The causes are fever or palsy, whence he forms two species: the latter he calls *organic*, arising from some affection in the membrane of the tongue, by which relishing things, or those which have some taste, are prevented from coming into contact with the nerves; the other *atonic*, arising without any affection of the tongue.

AGGLUTINA'NTIA. Adhesive medicines which heal by causing the parts to stick together.

AGGLUTINA'TION. (*Agglutinatio*; from *ad* and *glutino*, to glue together.) The adhesive union or sticking together of substances.

AGGLUTI'TIO. Obstruction in the œsophagus, or a difficulty in swallowing.

AGGREGATE. (*Aggregatus*; from *aggrego*, to assemble together.) Aggregated or added together. 1. When bodies of the same kind are united, the only consequence is, that one larger body is produced. In this case, the united mass is called an aggregate, and does not differ in its chemical properties from the bodies from which it was originally made. Elementary writers call the smallest parts into which an aggregate can be divided without destroying its chemical properties, integrant parts. Thus the integrant parts of common salt are the smallest parts which can be conceived to remain without change; and beyond these, any further subdivision cannot be made without developing the component parts, namely, the alcali and the acid; which are still further resolvable into their constituent principles.

2. A term applied to glands, flowers, gems, &c. An aggregate flower is one which consists of a number of smaller flowers or fructifications, collected into a head by means of some part common to them all. In this view aggregate flowers are opposed to simple flowers which have a single fructification, complete in its parts, nine of which are common to many flowers.

AGGREGATE GEM. A term applied in botany when two, three, or even more gems appear at the same time.

AGGREGATE GLANDS. (From *aggrego*, to assemble together.) *Glandulæ aggregatæ.* An assemblage of glands, as those on some parts of the internal surface of the intestines.

AGGREGATE PEDUNCLE. Clustered flower stalks, so called when several grow together, as in *verbascum nigrum.*

Aggregation, affinity of. See *Attraction.*

Aggregation, attraction of. See *Attraction.*

AGGREGATUS. See *Aggregate.*

AGHEU'STIA. See *Ageustia.*

A'GIS. The thigh or femur.

AGITATO'RIA. Convulsive diseases.

AGLACTA'TIO. Defect of milk.

AGLA'XIS. Defect of milk.

AGLIUM. 1. A shining tubercle or pustule on the face.

2. A white speck on the eye. See *Ægides.*

A'GMA. *Agme,* A fracture.

A'GNACAL. A tree, which, according to Ray, grows about the isthmus of Darien, and resembles a pear-tree, the fruit of which is a great provocative to venery.

AGNA'TA. See *Adnata tunica.*

AGNI'NA. (*Agnina*; from *agnus*, a lamb.) Aëtius calls one of the membranes which involve the fœtus by the name of *membrana agnina*, which he derives from its tenderness. See *Amnios.*

AGNOI'A. (From α, priv. and γινωσκω, to know.) Forgetfulness.

A'GNUS. A lamb.

AGNUS CASTUS. (Called *agnus*, from the down upon its surface, which resembles that upon a lamb's skin; and *castus*, because the chaste matrons, at the feasts of Ceres, strewed them upon their beds and lay upon them.) See *Vitex agnus castus.*

AGO'CE. 1. The deduction or reasoning upon diseases from their symptoms and appearances.

2. The order, state, or tenour of a disease or body.

AGOMPHI'ASIS. A looseness of the teeth.

A'GONE. (Αγονη; from α, neg. and γονος, offspring: so called because it was supposed to cause barrenness.) Henbane. See *Hyosciamus niger.*

AGO'NIA. Sterility, impotence, agony.

AGONI'STICUM. (Αγωνιςικον; from αγωνιαω, to struggle.) A term used by ancient physicians to signify water extremely cold, which was directed to be given in large quantities, in acute erysipelatous fevers, with a view of overpowering or struggling with the febrile heat of the blood.

A'GONOS. (From α, priv. and γονος, or γονη, an offspring.) Barren. Hippocrates calls those women so who have not children, though they might have if the impediment were removed.

AGO'STOS. (From αγω, to bring, or lead.) That part of the arm from the elbow to the fingers; also, the palm or hollow of the hand.

AGRE'STA. (Αγριος, wild.) 1. The immature fruit of the vine.

2. Verjuice, which is made from the wild apple.

AGRE'STEN. Common tartar.

AGRE'STIS. 1. Pertaining to the field; the trivial name of many plants.

2. In the works of some old writers, it expresses an ungovernable malignity in a disease.

A'GRIA. 1. A name of the *Ilex aquifolium,* or common holly.

2. A malignant pustule, of which the ancient surgeons, and particularly Celsus, describe two sorts; one, which has been so called, is small, and casts a roughness or redness over the skin, slightly corroding it; smooth about its centre; spreads slowly; and is of a round figure. The second ulcerates, with a violent redness and corrosion, so as to make the hair fall off; it is of an unequal form, and turns leprous.

AGRIA'MPELOS. (From αγριος, wild, and αμπελος, a vine.) The wild vine, or white bryony. See *Bryonia.*

AGRIELÆ'A. (From αγριος, wild, and ελαια, the olive-tree.) The oleaster, or wild olive.

AGRI'FOLIUM. (From ακις, a prickle, and φυλλὸν, a leaf.) The holly-tree. Which should rather be called *acifolium*, from its prickly leaves.

AGRIMO'NIA. (*Agrimonia, æ,* f.; from αγρος, a field, and μονος, alone: so named from its being the chief of all wild herbs.) Agrimony.

1. The name of a genus of plants in the Linnæan system. Class *Dodecandria*; Order, *Digynia.*

2. The pharmacopœial name of the common agrimony. See *Agrimonia eupatoria.*

AGRIMONIA EUPATORIA. The systematic name of the common agrimony. *Agrimonai* of the pharmacopœias; *Agrimonia—foliis caulinis pinnatis, foliolis undique serratis, omnibus minutis interstinctis, fructibus hispidis* of Linnæus. It is common in fields about hedges and shady places, flowering in June and July. It has been principally regarded in the character of a mild astringent and corroborant, and many authors recommend it as a deobstruent, especially in hepatic and other visceral obstructions. Chomel relates two instances of its successful use in cases where the liver was much enlarged and indurated. It has been used with advantage in hæmorrhagic affections, and to give tone to a lax and weak state of the solids. In cutaneous disorders, particularly in scabies, we have been told that it manifests great efficacy. For this purpose it was given infused with liquorice in the form of tea; but, according to Alston, it should be always exhibited in the state of powder. It is best used while fresh, and the tops, before the flowers are formed, possess the most virtue. Cullen observes that the agrimony has some astringent powers, but they are feeble; and pays little attention to what has been said in its favour.

AGRIMONY. See *Agrimonia.*

Agrimony hemp. See *Bidens tripartita.*

AGRIOCA′RDAMUM. (From *αγριος*, wild, and *καρδαμον*, the nasturtium.) Sciatica cresses, or wild garden cress.

AGRIOCA′STANUM. (From *αγριος*, wild, and *καςανον*, the chestnut.) Earth of pig-nut. See *Bunium bulbo-castanum.*

AGRIOCI′NARA. (From *αγριος*, wild, and *κιναρα*, artichoke.) Wild artichoke; not so good as the cultivated for any purpose. See *Cinara scolymus.*

AGRIOCOCCIME′LA. (From *αγριος*, wild, *κοκκος*, a berry, and *μηλεα*, an apple-tree.) The *Prunus spinosa* of Linnæus.

AGRIOME′LA. The crab-apple.

A′GRION. *Agriophyllon.* The *peucedanum silaus*, or hog's fennel.

AGRIOPASTINA′CA. (From *αγριος*, wild, and *pastinaca*, a carrot.) Wild carrot, or parsnip.

AGRIOPHY′LLON. See *Agrion.*

AGRIORI′GANUM. (From *αγριος*, wild, and *οριγανον*, marjoram.) Wild marjoram. See *Origanum vulgare.*

AGRIOSELI′NUM. (From *αγριος*, wild, and *σελινον*, parsley.) Wild parsley. See *Smyrnium olusatrum.*

AGRIOSTA′RI. (From *αγριος*, wild, and *ςαις*, wheat.) Field-corn, a species of Triticum.

AGRIPA′LMA. (From *αγριος*, wild, and *ϖαλμα*, a palm-tree.) *Agripalma gallis.* The herb mother-wort, or wild-palm.

AGRIPA′LMA GALLIS. See *Agripalma.*

AGRI′PPÆ. Those children which are born with their feet foremost are so called, because that was said to be the case with Agrippa the Roman, who was named *ab ægro partu*, from his difficult birth.

A′GRIUM. An impure sort of natron. The purer sort was called *halmyrhaga.*

AGROSTEMMA. (*Αγρου ςεμμα*, the garland of the field.) The name of a genus of plants. Class, *Decandria*; Order, *Pentagynia.* Cockle.

AGROSTEMMA GITHAGO. This plant has been called *Nigellastrum*; *Pseudo melanthium*; *Lychnis segetum major*; *Githago*; *Nigella officinarum*; *Lychnoides segetum.* Cockle. It has no particular virtues, and is fallen into disuse.

AGROSTIS. (From *αγρος*, a field.) The name of a genus of plants. Class, *Triandria*; Order, *Digynia.* Bentgrass.

AGRU′MINA. Leeks; wild onions.

AGRY′PNIA. (From *α*, priv. and *υπνος*, sleep.) Watchfulness; sleeplessness. The name of a genus in Good's Nosology. See *Nosology.*

AGRYPNOCO′MA. (From *αγρυπνος*, without sleep, and *κωμα*, a lethargy.) A lethargic kind of watchfulness, in which the patient is stupidly drowsy, and yet cannot sleep.

AGUE. See *Febris Intermittens.*

Ague cake. The popular name for a hard tumour, most probably the spleen on the left side of the belly, lower than the false ribs in the region of the spleen, said to be the effect of intermittent fevers. However frequent it might have been formerly, it is now very rare, and although then said to be owing to the use of bark, it is now less frequent since the bark has been generally employed.

Ague drop. A medicine sold for the cure of agues, composed of arsenite of potassa in solution in water. The regular substitute for the quack medicine called the tasteless ague drop, which has cured thousands of that complaint, is the liquor arsenicalis.

Ague-free. A name given by some to sassafras, on account of its supposed febrifuge virtue.

AGUI′A. (From *α*, priv. and *γυιον*, a member.) Paralytic weakness of a limb. Where the use of the members is defective or lost.

A′GUL. *Alhagi.* An Arabian name for the Syrian thorn. The leaves are purgative.

AGUSTINE. (From *α*, priv. and *γευςια*, taste, that is tasteless.) *Augustina.* A new earth discovered in the Saxon beryl, or beryl of Georgien Stadt, (a stone greatly resembling the beryl of Siberia,) by Professor Tromsdorff, of Erfurth, in Germany, to which he has given the name of *agustine*, on account of the property of forming salts which are nearly destitute of taste. This earth is white and insipid: when moistened with water, it is somewhat ductile, but is not soluble in that fluid. Exposed to a violent heat, it becomes extremely hard, but acquires no taste. It combines with acids, forming salts which have little or no taste. It does not combine either in the humid or dry way with alcalies, or with their carbonates. It retains carbonic acid but feebly. It dissolves in acids equally well after having been hardened by exposure to heat, as when newly precipitated. With sulphuric acid it forms a salt which is insipid, and scarcely soluble, but an excess of acid renders it soluble, and capable of crystallizing in stars. With an excess of phosphoric acid it forms a very soluble salt. With nitrous acid it forms a salt scarcely soluble.

AGUTIGUEPOO′BI BRAZILIENSIS. An Indian name of the arrow-root. See *Maranta.*

AGYION. See *Aguia.*

AGY′RTÆ. (From *αγυρις*, a crowd of people, or a mob; or from *αγειρω*, to gather together.) It formerly expressed certain strollers, who pretended to strange things from supernatural assistances; it was afterwards applied to all illiterate dabblers in medicine. Now obsolete.

AHALOTH. The Hebrew name of lignum aloes. See *Lignum aloes.*

AHAME′LLA. See *Achmella.*

AHO′VAI THEVETICLUSH. A chestnut-like fruit of Brazil, of a poisonous nature.

AHU′SAL. Orpiment.

AI′LMAD. Antimony.

AIMATEI′A. A black bilious and blood-like discharge from the bowels.

AIMORRHŒ′A. See *Hæmorrhagia.*

AIMO′RRHOIS. See *Hæmorrhois.*

AIPATHEI′A. (From *αει*, always, and *ϖαθος*, a disease.) Diseases of long continuance.

AI′PI. *Aipima coxera. Aipipoca.* Indian words for Cassada. See *Jatropha manihot.*

AIR. This term was, till lately, used as the generic name for such invisible and exceedingly rare fluids as possess a very high degree of elasticity, and are not condensible into the liquid state by any degree of cold hitherto produced; but as this term is commonly employed to signify that compound of aëriform fluids which constitues our atmosphere, it has been deemed advisable to restrict it to this signification, and to employ as the generic term the word Gas, for the different kinds of air, except what relates to our atmospheric compound.

Air, atmospheric. "The immense mass of permanently elastic fluid which surrounds the globe we inhabit," says Dr. Ure, "must consist of a general assemblage of every kind of air which can be formed by the various bodies that compose its surface. Most of these, however, are absorbed by water; a number of them are decomposed by combination with each other; and some of them are seldom disengaged in considerable quantities by the processes of nature. Hence it is that the lower atmosphere consists chiefly of oxygen and nitrogen, together with moisture and the occasional vapours or exhalations of bodies. The upper atmosphere seems to be composed of a large proportion of hydrogen, a fluid of so much less specific gravity than any other, that it must naturally ascend to the highest place, where, being occasionally set on fire by electricity, it appears to be the cause of the aurora borealis and fire-balls. It may easily be understood, that this will only happen on the confines of the respective masses of common atmospherical air, and of the inflammable air; that the combustion will extend progressively, though rapidly, in flashings from the place where it commences; and that when by any means a stream of inflammable air, in its progress toward the upper atmosphere, is set on fire at one end, its ignition may be much more rapid than what happens higher up, where oxygen is wanting, and at the same time more definite in its figure and progression, so as to form the appearance of a fire-ball.

That the air of the atmosphere is so transparent as to be invisible except by the blue colour it reflects when in very large masses, as is seen in the sky or region above us, or in viewing extensive landscapes; that it is without smell, except that of electricity, which it sometimes very manifestly exhibits; altogether without taste, and impalpable; not condensible by any degree of cold into the dense fluid state, though easily changing its dimensions with its temperature; that it gravitates and is highly elastic; are among the numerous observations and discoveries which do honour to the sagacity of the philosophers of the seventeenth century. They likewise knew that this fluid is indispensably necessary to combustion, but no one, except the great, though neglected, John Mayow, appears to have formed any proper notion of its manner of acting in that process.

The air of the atmosphere, like other fluids, appears to be capable of holding bodies in solution. It takes up water in considerable quantities, with a diminution of its own specific gravity: from which circumstance, as well as from the consideration that water rises very plentifully in the vaporous state *in vacuo*, it seems probable, that the air suspends vapour, not so much by a real solution, as by keeping its particles asunder, and preventing their condensation. Water likewise dissolves or absorbs air.

Mere heating or cooling does not affect the chemical properties of atmospherical air; but actual combustion, or any process of the same nature, combines its oxygen, and leaves its nitrogen separate. Whenever a process of this kind is carried on in a vessel containing atmospherical air, which is enclosed either by inverting the vessel over mercury or by stopping its aperture in a proper manner, it is found that the process ceases after a certain time; and that the remaining air (if a combustible body capable of solidifying the oxygen, such as phosphorus, have been employed,) has lost about a fifth part of its volume, and is of such a nature as to be incapable of maintaining any combustion for a second time, or of supporting the life of animals. From these experiments it is clear, that one of the following deductions must be true:—1. The combustible body has emitted some principle, which, by combining with the air, has rendered it unfit for the purpose of further combustion; or, 2. It has absorbed part of the air which was fit for that purpose, and has left a residue of a different nature; or, 3. Both events have happened; namely, that the pure part of the air has been absorbed, and a principal has been emitted, which has changed the original properties of the remainder.

The facts must clear up these theories. The first induction cannot be true, because the residual air is not only of less bulk, but of less specific gravity, than before. The air cannot therefore have received so much as it has lost. The second is the doctrine of the philosophers who deny the existence of phlogiston, or a principle of inflammability; and the third must be adopted by those who maintain that such a principle escapes from bodies during combustion. This residue was called phlogisticated air, in consequence of such an opinion.

In the opinion that inflammable air is the phlogiston, it is not necessary to reject the second inference that the air has been no otherwise changed than by the mere subtraction of one of its principles; for the pure or vital part of the air may unite with inflammable air supposed to exist in a fixed state in the combustible body; and if the product of this union still continues fixed, it is evident, that the residue of the air, after combustion, will be the same as it would have been if the vital part had been absorbed by any other fixed body. Or, if the vital air be absorbed while inflammable air or phlogiston is disengaged, and unites with the aëriform residue, his residue will not be heavier than before, unless the inflammable air it has gained exceeds in weight the vital air it has lost; and if the inflammable air falls short of that weight, the residue will be lighter.

These theories it was necessary to mention; but it has been sufficiently proved by various experiments, that combustible bodies take oxygen from the atmosphere, and leave nitrogen; and that when these two fluids are again mixed in due proportions, they compose a mixture not differing from atmospherical air.

The respiration of animals produces the same effect on atmospherical air as combustion does, and their constant heat appears to be an effect of the same nature. When an animal is included in a limited quantity of atmospherical air, it dies as soon as the oxygen is consumed; and no other air will maintain animal life but oxygen, or a mixture which contains it. Pure oxygen maintains the life of animals much longer than atmospherical air, bulk for bulk.

It is to be particularly observed, however, that, in many cases of combustion, the oxygen of the air, in combining with the combustible body, produces a compound, not solid or liquid, but aëriform. The residual air will therefore be a mixture of the nitrogen of the atmosphere with the consumed oxygen, converted into another gas. Thus, in burning charcoal, the carbonic acid gas generated, mixes with the residual nitrogen, and makes up exactly, when the effect of heat ceases, the bulk of the original air. The breathing of animals, in like manner, changes the oxygen into carbonic acid gas, without altering the atmospherical volume.

There are many provisions in nature by which the proportion of oxygen in the atmosphere, which is continually consumed in respiration and combustion, is again restored to that fluid. In fact there appears as far as an estimate can be formed of the great and general operations of nature, to be at least as great an emission of oxygen as is sufficient to keep the general mass of the atmosphere at the same degree of purity. Thus, in volcanic eruptions, there seems to be at least as much oxygen emitted or extricated by fire from various minerals, as is sufficient to maintain the combustion, and perhaps even to meliorate the atmosphere. And in the bodies of plants and animals, which appear in a great measure to derive their sustenance and augmentation from the atmosphere and its contents, it is found that a large proportion of nitrogen exists. Most plants emit oxygen in the sunshine, from which it is highly probable that they imbibe and decompose the air of the atmosphere, retaining carbon, and emitting the vital part. Lastly, if to this we add the decomposition of water, there will be numerous occasions in which this fluid will supply us with disengaged oxygen; while, by a very rational supposition, its hydrogen may be considered as having entered into the bodies of plants for the formation of oils, sugars, mucilages, &c. from which it may be again extricated.

To determine the respirability or purity of air, it is evident that recourse must be had to its comparative efficacy in maintaining combustion, or some other equivalent process.

From the latest and most accurate experiments, the proportion of oxygen in atmospheric air is by measure about 21 per cent.; and it appears to be very nearly the same, whether it be in this country or on the coast of Guinea, on low plains or lofty mountains, or even at the height of 7250 yards above the level of the sea, as ascertained by Gay Lussac, in his aërial voyage in September 1805. The remainder of the air is nitrogen, with a small portion of aqueous vapour, amounting to about 1 per cent. in the driest weather, and a still less portion of carbonic acid, not exceeding a thousandth part of the whole.

As oxygen and nitrogen differ in specific gravity in the proportion of 135 to 121, according to Kirwan, and of 139 to 120, according to Davy, it has been presumed, that the oxygen would be more abundant in the lower regions, and the nitrogen in the higher, if they constituted a mere mechanical mixture, which appears contrary to the fact. On the other hand, it has been urged, that they cannot be in the state of chemical combination, because they both retain their distinct properties unaltered, and no change of temperature or density takes place on their union. But perhaps it may be said, that, as they have no repugnance to mix with each other, as oil and water have, the continual agitation to which the atmosphere is exposed, may be sufficient to prevent two fluids, differing not more than oxygen and nitrogen in gravity, from separating by subsidence, though simply mixed. On the contrary, it may be argued, that to say chemical combination cannot take place without producing new properties, which did not exist before in the component parts, is merely begging the question; for though this generally appears to be the case, and often in a very striking manner, yet combination does not always produce a change of properties, as appears in M. Biot's experiments with various substances; of which we may instance water, the refraction of which is precisely the mean of that of the oxygen and hydrogen, which are indisputably combined in it.

To get rid of the difficulty, Mr. Dalton of Manchester framed an ingenious hypothesis, that the particles of different gases neither attract nor repel each other; so that one gas expands by the repulsion of its own particles, without any more interruption from the presence of another gas, than if it were in a vacuum. This would account for the state of atmospheric air, it is true; but it does not agree with certain facts. In the case of the carbonic acid gas in the Grotto del Cano, and over the surface of brewers' vats, why does not this gas expand itself freely upward, if the superincumbent gases do not press upon it? Mr. Dalton himself, too, instances as an argument for his hypothesis, that oxygen and hydrogen gases, when mixed by agitation, do not separate on standing. But why should either oxygen or dydrogen require agitation, to diffuse it through a vacuum, in which, according to Mr. Dalton, it is placed?

The theory of Berthollet appears consistent with all the facts, and sufficient to account for the phenomenon. If two bodies be capable of chemical combination, their particles must have a mutual attraction for each other. This attraction, however, may be so opposed by concomitant circumstances, that it may be diminished in any degree. Thus we know, that the affinity of aggregation may occasion a body to combine slowly with a substance for which it has a powerful affinity, or even entirely prevent its combining with it; the presence of a third substance may equally prevent the combination; and so may the absence of a certain quantity of caloric. But in all these cases the attraction of the particles must subsist, though diminished or counteracted by opposing circumstances. Now we know that oxygen and nitrogen are capable of combination; their particles, therefore, must attract each other; but in the circumstances in which they are placed in our atmosphere, that attraction is prevented from exerting itself, to such a degree as to form them into a chemical compound, though it operates with sufficient force to prevent their separating by their difference of specific gravity. Thus the state of the atmosphere is accounted for, and every difficulty obviated, without any new hypothesis.

The exact specific gravity of atmospherical air, compared to that of water, is a very nice and important problem. By reducing to 60° Fahr. and to 30 inches of the barometer, the results obtained with great care by Biot and Arago, the specific gravity of atmospherical air, appears to be 0.001220, water being represented by 1.000000. This relation expressed fractionally is 1 : 820, or water is 820 times denser than atmospherical air. Mr. Rice, in the 77th and 78th numbers of the Annals of Philosophy, deduces from Sir George Shuckburgh's experiments 0.00120855 for the specific gravity of air. This number gives water to air as 827.437 to 1. If with Mr. Rice we take the cubic inch of water = 252.525 gr., then 100 cubic inches of air by Biot's experiments will weigh 30.808 grains, and by Mr. Rice's estimate 30.519. He considers with Dr. Prout the atmosphere to be a compound of 4 volumes of nitrogen, and 1 of oxygen; the specific gravity of the first being to that of the second as 1.1111 to 0.9722. Hence

0.8 vol. nitr. sp. gr. 0.001166 = 0.000933
0.2 oxy. 0.001340 = 0.000268

0.001201

The numbers are transposed in the Annals of Philosophy by some mistake.

Biot and Arago found the specific gravity of
oxygen to be - - 1.10359
and that of nitrogen, - - 0.96913
air being reckoned, - - 1.00000

Or compared to water as unity,—
Nitrogen is 0.001182338
Oxygen, 0.001346379

And 0.8 nitrogen = 0.00094587
0.2 oxygen = 0.00026927

0.00121514

And 0.79 nitrogen = 0.000934
0.21 oxygen = 0.000283

0.001217

A number which approaches very nearly to the result of experiment. Many analogies, it must be confessed, favour Dr. Prout's proportions; but the greater number of experiments on the composition and density of the atmosphere agree with Biot's results. Nothing can decide these fundamental chemical proportions, except a new, elaborate, and most minutely accurate series of experiments. We shall then know whether the atmosphere contains in volume 20 or 21 per cent. of oxygen."—*Ure's Chem. Dict.*

Air, alcaline. See *Ammonia.*

Air, azotic. See *Nitrogen.*

Air, fixed. See *Carbonic acid.*

Air, fluoric. See *Fluoric acid.*

Air, hepatic. See *Hydrogen sulphuretted.*

Air, heavy inflammable. See *Carburetted hydrogen.*

Air, inflammable. See *Hydrogen.*

Air, marine. See *Muriatic acid.*

Air, nitrous. See *Nitrous.*

Air, phlogisticated. See *Nitrogen.*

Air, phosphoric. See *Hydrogen phosphuretted.*

Air, sulphureous. See *Sulphureous acid.*

AISTHETE'RIUM. (From αισθανομαι, to perceive.) The sensorium commune, or common sensory, or seat, or origin of sensation.

AITHMAD. Antimony.

AIX LA CHAPE'LLE. Called Aken by the Germans. A town in the south of France, where there is a sulphureous water, Thermæ Aquis-granensis, the most striking feature of which, and what is almost peculiar to it, is the unusual quantity of sulphur it contains: the whole, however, is so far united to a gaseous basis, as to be entirely volatilized by heat; so that none is left in the residuum after evaporation. In colour it is pellucid, in smell sulphureous, and in taste saline, bitterish, and rather alcaline. The temperature of these waters varies considerably, according to the distance from the source and the spring itself. In the well of the hottest bath, it is, according to Lucas, 136°, Monet, 146°; at the fountain where it is drank, it is 112°. This thermal water is much resorted to on the Continent for a variety of complaints. It is found essentially serviceable in the numerous symptoms of disorders in the stomach and biliary organs, that follow a life of high indulgence in the luxuries of the table; in nephritic cases, which produce pain in the loins, and thick mucous urine with difficult micturition. As the heating qualities of this water are as decided as in any of the mineral springs, it should be avoided in cases of a general inflammatory tendency, in hectic fever and ulceration of the lungs; and in a disposition to active hæmorrhagy. As a hot bath, this water is even more valuable and more extensively employed than as an internal remedy. The baths of Aix la Chapelle may be said to be more particularly medicated than any other that we are acquainted with. They possess both temperature of any degree that can be borne; and a strong impregnation with sulphur in its most active forms; and a quantity of alcali, which is sufficient to give it a very soft soapy feel, and to render it more detergent than common water. From these circumstances, these baths will be found of particular service in stiffness and rigidity of the joints and ligaments, which is left by the inflammation of gout and rheumatism, and in the debility of palsy, where the highest degree of heat which the skin can bear is required. The sulphureous ingredient renders it highly active in almost every cutaneous eruption, and in general in every foulness of the skin; and here the internal use of the water should attend that of the bath. These waters are also much employed in the distressing debility which follows a long course of mercury and excessive salivation. Aken water is one of the few natural springs that are hot enough to be employed as a vapour bath, without the addition of artificial heat. It is employed in cases in which the hot bath is used; and is found to be a remarkably powerful auxiliary in curing some of the worst species of cutaneous disorders. With regard to the dose of this water to be begun with, or the degree of heat to bathe in, it is in all cases best to begin with small quantities and low degrees of heat, and gradually increase them, agreeably to the effects and constitution of the patient. The usual time of the year for drinking these waters is from the beginning of May to the middle of June, or from the middle of August to the latter end of September.

AIZO'ON. (From αει, always, and ζω, to live.) *Aizoum.* 1. An evergreen aquatic plant, like the aloe, said to possess antiscorbutic virtues.

2. The house leek. See *Sempervivum tectorum.*

AIZOUM. See *Aizoon.*

AJA'VA. An Indian name of a seed used in the East as a remedy for the colic.

AJUGA. (From α, priv. and ζυγον, a yoke.) 1. The name of a genus of plants in the Linnæan system.

2. The pharmacopœial name of the creeping bugloss. See *Ajuga pyramidalis.*

AJUGA PYRAMIDALIS. *Consolida media. Bugula.* Upright bugloss. Middle consound. This plant, *Ajuga—caule tetragono foliis radicalibus maximis*, of Linnæus, possesses subadstringent and bitter qualities: and has been recommended in *phthisis*, *aphthæ*, and *cynanche.*

AJURA'RAT. Lead.

A'KENSIDE, MARK. An English physician, born at Newcastle-upon-Tyne, in 1721; but more distinguished as a poet, especially for his "Pleasures of the Imagination." After studying at Edinburgh, and graduating at Leyden, he settled in practice; but though appointed physician to the Queen, as well as to St. Thomas's Hospital, he is said not to have been very successful. He died of a putrid fever, in his 49th year. He has left a Dissertation on Dysentery in Latin, admired for its elegance; and several small Tracts in the Philosophical and London Medical Transactions.

AL. The Arabian article, which signifies *the*; it is applied to a word by way of eminence, as the Greek *o* is. The Easterns express the superlative by adding *God* thereto, as *the mountain of God*, for the highest mountain; and it is probable that *Al* relates to the word *Alla*, God: so *Alchemy*, may be *the chemistry of God*, or the most exalted perfection of chemical science.

A'LA. 1. The wing of a bird.

2. The arm-pit, so called because it answers to the pit under the wing of a bird.

3. An accidental part of the seed of a plant; consisting of a membraneous prolongation from the side of the seed, and distinguished by the number into

Semina monoterygia: one-winged, as in *Bignonia.*

Dipterygia: two-winged, as in *Betula.*

Tripterygia: three-winged.

Tetrapterygia; four-winged.

Polypterigia: many-winged, or *Molendinacea*: windmill-winged, for so the many-winged seeds of some umbelliferous plants are termed.

4. The two lateral or side petals of a papilionaceous or butterfly-shaped flower.

ALA AURIS. The upper part of the external ear.

ALA INTERNA MINOR. See *Nymphæ.*

ALA NASI. 1. The cartilage of the nose which forms the outer part of the nostrils.

2. The sides of the nose are called *alæ nasi.*

ALA VESPERTILIONIS. That part of the ligament of the womb, which lies between the tubes and the ovarium; so called from its resemblance to the wing of a bat.

ALA′BARI. Lead.

ALABASTER. Among the stones which are known by the name of marble, and have been distinguished by a considerable variety of denominations by statuaries and others, whose attention is more directed to their external character and appearance than their component parts, alabasters are those which have a greater or less degree of imperfect transparency, a granular texture, are softer, take a duller polish than marble, and are usually of a white colour. Some stones, however, of a veined and coloured appearance, have been considered as alabasters, from their possessing the first-mentioned criterion; and some transparent and yellow sparry stones have also received this appellation.

A′LACAR. Sal ammoniac.

ALÆFO′RMIS. (*Alæformis*; from *Ala*, a wing, and *forma*, resemblance.) Wing-like. Any thing like a wing.

A′LAFI. *Alafor.* *Alafort.* Alcaline.

ALAI′A PHTHI′SIS. (From ἀλαιὸς, blind, and φθισις, a wasting.) A consumption from a flux of humours from the head.

A′LAMAD. *Alamed.* Antimony.

ALA′MBIC. Mercury.

ALANDAHLA. The Arabian for bitter. The bitter apple. See *Cucumis colocynthis.*

ALANFU′TA. An Arabian name of a vein between the chin and lower lip, which was formerly opened to prevent fœtid breath.

ALAPOU′LI. See *Bilimbi.*

ALARIA OSSA. The wing-like processes of the sphenoid bone.

ALA′RIS. (*Alaris*; from *ala*, a wing.) Formed like, or belonging to a wing.

ALARIS EXTERNUS. *Musculus alaris externus.* A name of the external pterygoid muscle; so called because it takes its rise from the wing-like process of the sphenoid bone.

ALARIS VENA. The innermost of the three veins in the bend of the arm.

ALASALET. *Alaset.* Ammoniacum.

ALASI. *Alafor.* An alcaline salt.

ALA′STROB. Lead.

A′LATAN. Litharge.

ALATE′RNUS. A species of rhamnus.

ALA′TUS. (From *ala*, a wing.) Winged. 1. Applied to stems and leaf-stalks, when the edges or angles are longitudinally expanded into leaf-like borders; as in *Ænopordium acanthium*; *Lathyrus latifolius*, &c. and the leaf-stalk of the orange tribe, citrus, &c.

2. One who has prominent scapulæ like the wings of birds.

ALAU′RAT. Nitre.

ALBADAL. An Arabic name for the sesamoid bone of the first joint of the great toe.

ALBAGE′NZI. *Albagiazi.* Arabic names for the os sacrum.

ALBAGRAS NIGRA. So Avicenna names the *Lepra ichthyosis*, or *Lepra Græcorum.*

ALBAME′NTUM. (From *albus*, white.) The white of an egg.

ALBA′NUM. Urinous salt.

ALBA′RA. (Chaldean.) The white leprosy.

ALBARAS. 1. Arsenic.

2. A white pustule.

ALBA′TIO. (From *albus*, white.) *Albificatio.* The calcination or whitening of metals.

A′LBERAS. (Arabian.) White pustules on the face: also, staphisagria, because its juice was said to remove these pustules.

ALBE′STON. Quick lime.

A′LBETAD. Galbanum.

A′LBI SUBLIMATI. Muriated mercury.

A′LBICANS. (From *albico*, to grow white.) Inclining to white. Whitish.

ALBICA′NTIA CO′RPORA. *Corpora albicantia Willisii.* Two small round bodies or projections from the base of the brain, of a white colour.

A′LBIMEC. Orpiment. See *Arsenic.*

ALBIN. A mineral found in Bohemia; so called from its white colour.

ALBI′NUM. See *Gnaphalium dioicum.*

ALBI′NUS BERNARD SIEGFRED, son of a physician, and professor at Leyden of the same name, was born near the end of the 17th century, and prosecuted his studies with so much zeal and success, that he was appointed, on the recommendation of Boerhaave, professor of anatomy and surgery, when only 20 years old. This office he filled for half a century, and acquired a greater reputation than any of his predecessors. He has left several valuable anatomical works; and particularly very accurate descriptions, and plates of the muscles and bones, which are still highly esteemed.

A′LBOR. Urine.

A′LBORA. A sort of itch; or rather of leprosy. Paracelsus says, it is a complication of the morphew, serpigo, and leprosy. When cicatrices appear in the face like the serpigo, and then turn to small blisters of the nature of the morphew, it is the albora. It terminates without ulceration, but by fœtid evacuations in the mouth and nostrils; it is also seated in the root of the tongue.

ALBO′REA. Quicksilver.

A′LBOT. A crucible.

ALBO′TAI. Turpentine.

A′LBOTAR. Turpentine.

A′LBOTAT. White lead.

A′LBOTIM. Turpentine.

A′LBOTIS. A cutaneous phlegmon or boil.

ALBUCA′SIS, an Arabian physician and surgeon of considerable merit, who lived about the beginning of the twelfth century. He has copied much from preceding writers, but added also many original observations; and his works may be still perused with pleasure. He insisted on the necessity of a surgeon being skilled in anatomy to enable him to operate with success, as well as acquainted with the materia medica, that he may apply his remedies with propriety. He appears to have extracted polypi from the nose, and performed the operation of bronchotomy. He is the first who left distinct descriptions and delineations of the instruments used in surgery, and of the manner of employing them.

ALBUGI′NEA. (*Albuginia*; from *albus*, white: so called on account of its white colour.)

The name of a membrane of the eye and of the testicle.

ALBUGINEA OCULI. See *Adnata tunica.*

ALBUGINEA TESTIS. *Tunica albuginea testis.* The innermost coat of the testicle. A strong, white, and dense membrane, immediately covering the body or substance of the testicle. On its outer surface it is smooth, but rough and uneven on the inner. See *Testicle.*

ALBU'GO. A white opacity of the cornea of the eye. The Greeks named it *leucoma;* the Latins, *albugo*, *nebula*, and *nubecula.* Some ancient writers have called it *pterygium*, *janua oculi*, *onyx*, *unguis*, and *ægides.* It is a variety of Cullen's *Caligo corneæ.*

ALBUHAR. White lead.

ALBUM BALSAMUM. The balsam of copaiba. See *Copaiba.*

ALBUM GRÆCUM. The white dung of dogs. It was formerly applied as a discutient, to the inside of the throat, in quinsies, being first mixed with honey; medicines of this kind have long since justly sunk into disuse.

ALBUM OLUS. See *Valeriana locusta.*

ALBU'MEN. *Albumine.* 1. Coagulable lymph. This substance, which derives its name from the Latin for the white of an egg, in which it exists abundantly, and in its purest natural state, is one of the chief constituent principles of all the animal solids. Beside the white of egg, it abounds in the serum of blood, the vitreous and crystalline humours of the eye, and the fluid of dropsy. Fourcroy claims to himself the honour of having discovered it in the green feculæ of plants in general, particularly in those of the cruciform order, in very young ones, and in the fresh shoots of trees, though Rouelle appears to have detected it there long before. Vauquelin says it exists also in the mineral water of Plombieres.

Seguin has found it in remarkable quantity in such vegetables as ferment without yeast, and afford a vinous liquor; and from a series of experiments, he infers, that albumen is the true principle of fermentation, and that its action is more powerful in proportion to its solubility, three different degrees of which he found it to possess.

The chief characteristic of albumen is its coagulability by the action of heat. If the white of an egg be exposed to a heat of about 134° F. white fibres begin to appear in it, and at 160° it coagulates into a solid mass. In a heat not exceeding 212 it dries, shrinks, and assumes the appearance of horn. It is soluble in cold water before it has been coagulated, but not after; and when diluted with a very large portion, it does not coagulate easily. Pure alcalies dissolve it, even after coagulation. It is precipitated by muriate of mercury, nitro-muriate of tin, acetate of lead, nitrate of silver, muriate of gold, infusion of galls, and tannin. The acids and metallic oxydes coagulate albumen. On the addition of concentrated sulphuric acid, it becomes black, and exhales a nauseous smell. Strong muriatic acid gives a violet tinge to the coagulum, and at length becomes saturated with ammonia. Nitric acid, at 70° F. disengages from it abundance of azotic gas; and if the heat be increased, prussic acid is formed; after which carbonic acid and carburetted hydrogen are evolved, and the residue consists of water containing a little oxalic acid, and covered with a lemon-coloured fat oil. If dry potassa or soda be triturated with albumen, either liquid or solid, ammoniacal gas is evolved, and the calcination of the residuum yields an alcaline prussiate.

On exposure to the atmosphere in a moist state, albumen passes at once to the state of putrefaction.

Solid albumen may be obtained by agitating white of egg with ten or twelve times its weight of alcohol. This seizes the water which held the albumen in solution; and this substance is precipitated under the form of white flocks or filaments, which cohesive attraction renders insoluble, and which consequently may be freely washed with water. Albumen thus obtained is like fibrine, solid, white, insipid, inodorous, denser than water, and without action or vegetable colours. It dissolves in potassa and soda more easily than fibrine; but in acetic acid and ammonia, with more difficulty. When these two animal principles are separately dissolved in potassa, muriatic acid added to the albuminous, does not disturb the solution, but it produces a cloud in the other.

Fourcroy and several other chemists have ascribed the characteristic coagulation of albumen by heat to its oxygenation. But cohesive attraction is the real cause of the phenomenon. In proportion as the temperature rises, the particles of water and albumen recede from each other, their affinity diminishes, and then the albumen precipitates However, by uniting albumen with a large quantity of water, we diminish its coagulating property to such a degree, that heat renders the solution merely opalescent. A new-laid egg yields a soft coagulum by boiling; but when, by keeping, a portion of the water has transuded so as to leave a void space within the shell, the concentrated albumen affords a firm coagulum.

An *analogous phenomenon* is exhibited by acetate of alumina, a solution of which, being heated, gives a precipitate in flakes, which redissolve as the caloric which separated the particles of acid and base escapes, or as the temperature falls. A solution containing 1-10 of dry albumen forms by heat a solid *coagulum;* but when it contains only 1-15, it gives a glary liquid. One-thousandth part, however, on applying heat, occasions opalescence. Putrid white of egg, and the *pus* of ulcers, have a similar smell. According to Dr. Bostock, a drop of a saturated solution of corrosive sublimate let fall into water containing 1-2000 of albumen, occasions a milkiness and curdy precipitate. On adding a slight excess of the mercurial solution to the albuminous liquid, and applying heat, the precipitate which falls, being dried, contains in every 7 parts 5 of albumen. Hence that salt is the most delicate test of this animal product. The yellow pitchy precipitate occasioned by tannin, is brittle when dried, and not liable to putrefaction. But tannin, or infusion of galls, is a much nicer test of gelatin than of albumen.

The cohesive attraction of coagulated albumen makes it resist putrefaction. In this state it may be kept for weeks under water without suffering change. By long digestion in weak nitric acid, albumen seems convertible into gelatin. By the analysis of Gay Lussac and Thénard, 100 parts of albumen are formed of 52.883 carbon, 23.872 oxygen, 7.540 hydrogen, 15.705 nitrogen; or, in other terms, of 52.883 carbon, 27.127 oxygen and hydrogen, in the proportions for constituting water, 15.705 nitrogen, and 4.285 hydrogen in excess. The negative pole of a voltaic pile in high activity coagulates albumen; but if the pile be feeble, coagulation goes on only at the positive surface. Albumen, in such a state of concentration as it exists in serum of blood, can dissolve some metallic oxydes, particularly the protoxide of iron. Orfila has found white of egg to be the best antidote to the poisonous effects of corrosive sublimate on the human stomach. As albumen occasions precipitates with the solutions of almost every metallic salt, probably it may act beneficially against other species of mineral poison.

From its coagulability albumen is of great use in clarifying liquids.

It is likewise remarkable for the property of rendering leather supple, for which purpose a solution of whites of eggs in water is used by leather-dressers.—*Ure's Chem. Dict.*

2. In botany, the term *albumen* is applied to a farinaceous, fleshy, or horny substance, which makes up the chief bulk of some seeds, as grapes, corn, palms, lilies, never rising out of the ground, nor assuming the office of leaves, being destined solely to nourish the germinating embryo, till its roots perform their office. In the date palm, this part is nearly as hard as stone, in *mirabilis* it is like wheat-flour. It is wanting in several tribes of plants, as those with compound or with cruciform flowers, and the cucumber or gourd kind, according to Gardner. Some few leguminous plants have it, and a great number of others, which, like them, have cotyledons besides. We are not, however, to suppose, that so important an organ is altogether wanting, even in the above-mentioned plants. The farinaceous matter destined to nourish their embryos, is unquestionably lodged in their cotyledons, the sweet taste of which, as they begin to germinate, often evinces its presence, and that it has undergone the same change as in barley. The albumen of the nutmeg is remarkable for its eroded variegated appearance, and aromatic quality; the cotyledons of this plant are very small.—*Smith.*

ALBUMEN OVI. *Albugo ovi; Albumen albor ovi; Ovi albus liquor; Ovi candidum albumentum; Clareta.* The white of an egg.

ALBURNUM. (From *albus*, white.) The soft white substance, which, in trees, is found between the liber, or inner bark, and the wood. In process of time it acquires solidity, becoming itself the wood. While soft, it performs a very important part of the functions of growth, which ceases when it becomes hard. A new circle of alburnum it annually formed over the old, so that a transverse section of the trunk presents a pretty correct register of the tree's age, each zone marking one year. From its colour and comparative softness, it has been called by some writers, the *adeps arborum.* The alburnum is found in largest quantities in trees that are vigorous. In an oak six inches in diameter, this substance is nearly equal in bulk to the wood.

A'LBUS, White. This term is applied to many parts from their white colour; as *linea alba, lepra alba, macula alba,* &c.

A'LCAHEST. An Arabic word to express an universal dissolvent, which was pretended to by Paracelsus and Helmont. Some say that Paracelsus first used this word, and that it is derived from the German words *al* and *geest*, i. e. *all spirit:* and that Van Helmont borrowed the word, and applied it to his invention, which he called the universal dissolvent.

A'LCALI. (Arabian.) This word is spelt indifferently with a *c* or a *k*. See *Alkali.*

ALCALIZATION. The impregnating any spirituous fluid with an alcali.

ALCANNA. (Indian word.) See *Anchusa.*

A'LCAOL. The solvent for the preparation of the philosopher's stone.

ALCARRAZES. A species of porous pottery made in Spain.

A'LCEA. (*Alcea, æ.* f.; from αλκη, strength.) The name of a genus of plants in the Linnæan system. Class, *Monadelphia;* Order, *Polyandria.* Hollyhock.

ALCEA ÆGYPTIACA VILLOSA. See *Hibiscus Abelmoschus.*

ALCEA INDICA. See *Hibiscus Abelmoschus.*

ALCEA ROSEA. Common hollyhock. The flowers of this beautiful tree are said to possess adstringent and mucilaginous virtues. They are seldom used medicinally.

A'LCEBAR. See *Lignum aloes.*

A'LCEBRIS VIVUM. This signifies, according to Rulandus, Sulphur vivum.

A'LCHABRIC. Sulphur vivum.

A'LCHACHIL. Rosemary.

A'LCHARITH. Quicksilver.

ALCHEMIA. See *Alchemy.*

ALCHEMI'LLA. (*Alchemilla, æ.* f. So called because it was celebrated by the old alchemists.)

1. The name of a genus of plants in the Linnæan system. Class, *Tetrandria;* Order, *Monogynia.* Ladies' mantle.

2. The pharmacopœial name of the plant called ladies' mantle. See *Alchemilla vulgaris.*

ALCHEMILLA VULGARIS. Ladies' mantle. This plant, *Alchemilla:—Foliis lobatis* of Linnæus, was formerly esteemed as an adstringent in hæmorrhages, fluor albus, &c. given internally. It is fallen into disuse.

ALCHEMIST. One who practises the mystical art of alchemy.

A'LCHEMY. *Alchemia; Alchimia; Alkima.* That branch of chemistry which relates to the transmutation of metals into gold;—the forming a panacea or universal remedy,—an alcahest, or universal menstruum,—an universal ferment, and many other absurdities.

A'LCHIBRIC. Sulphur.

A'LCHIEN. This word occurs in the Theatrum Chemicum, and seems to signify that power in nature by which all corruption and generation are effected.

ALCHIMELEC. (Hebrew.) The Egyptian melilot.

ALCHIMIA. See *Alchemy.*

ALCHIMI'LLA. See *Alchemilla.*

A'LCHITRON. 1. Oil of Juniper.

2. Also the name of a dentifrice of Messue.

A'LCHLYS. A speck on the pupil of the eye, somewhat obscuring vision.

A'LCHUTE. The mulberry.

A'LCHYMY. Alchemy.

A'LCIMAD. Antimony.

A'LCOB. Sal-ammoniac.

ALCO'CALUM. Most probably the Indian name of the artichoke.

A'LCOFOL. Antimony.

A'LCOHOL. See *Alkohol.*

A'LCOLA. (Hebrew.) 1. The thrush.

2. Paracelsus gives this name to tartar, or excrement of urine, whether it appears as sand, mucilage, &c.

ALCOLI'TA. Urine.

ALCO'NE. Brass.

A'LCOR. Æs ustum.

A'LCTE. The name of a plant mentioned by Hippocrates, supposed to be the elder.

ALCU'BRITH. Sulphur.

ALCYO'NIUM. It is difficult to say what the Greeks called by this name. Dioscorides speaks of five sorts of it. It is a spongy plant-like substance, met with on the sea-shore, of different shapes and colours. This bastard sponge is calcined with a little salt, as a dentifrice, and is used to remove spots on the skin.

ALDER. See *Betula alnus.*

Alder, berry-bearing. See *Rhamnus frangula.*

Alder wine. See *Betula alnus.*

ALDRUM. See *Alzum.*

ALDUM. See *Alzum.*

ALE. *Cerevisia; Liquor cereris; Vinum hordeaceum.* A fermented liquor made from malt and hops, and chiefly distinguished from beer, made from the same ingredients, by the quantity of hops used therein, which is greater in beer, and therefore renders the liquor more bitter, and fitter for keeping. Ale, when well fermented, is a wholesome beverage, but seems to disagree with those subject to asthma, or any disorder of the respiration, or irregularity in the digestive organs. The old dispensatories enumerate several medicated ales, such as *cerevisia oxydorica*, for the eyes; *cerevisia antiarthritica*, against the gout; *cephalica*, *epileptica*, &c. See *Beer.*

ALEARA. A cucurbit.

ALE′BRIA. (From *alo*, to nourish.) An obsolete term for that which is nourishing.

A′LEC. *Alech.* Vitriol.

ALE′CHARITH. Mercury.

ALEI′MMA. (From αλειφω, to anoint.) An ointment.

ALEI′ON. (Αλειον, copious.) Hippocrates uses this word as an epithet for water.

ALEI′PHA. (From αλειφω, to anoint.) Any medicated oil.

ALELAI′ON. From αλς, salt, and ελαιον, oil.) Oil beat up with salt, to apply to tumours. Galen frequently used it.

ALE′MA. (From α, priv. and λιμος, hunger.) Meat, food, or any thing that satisfies the appetite.

ALE′MBIC. (*Alembicus.* Some derive it from the Arabian particle *al*, and αμβιξ; from αμβαινω, to ascend. Avicenna declares it to be Arabian.) Moorshead. A chemical utensil made of glass, metal, or earthenware, and adapted to receive volatile products from retorts. It consists of a body to which is fitted a conical head, and out of this head descends laterally a beak to be inserted into the receiver.

ALE′MBROTH. (A Chaldee word, importing the key of art.) 1. Some explain it as the name of a salt, *sal mercurii*, or *sal philosophorum & artis*; others say it is named *alembrot* and *sal fusionis* or *sal fixionis*. *Alembroth desiccatum* is said to be the *sal tartari*; hence this word seems to signify alkaline salt, which opens the bodies of metals by destroying their sulphurs, and promoting their separation from the ores. From analogy, it is supposed to have the same effect in conquering obstructions and attenuating viscid fluids in the human body.

2. A peculiar earth, probably containing a fixed alkali, found in the island of Cyprus, has also this appellation.

3. A solution of the corrosive sublimate, to which the muriate of ammonia has been added, is called sal alembroth.

ALE′MZADAR. Sal ammoniac.

ALE′MZADAT. Sal ammoniac.

ALEPE′NSIS. A species of ash-tree which produces manna.

A′LES. (From αλς, salt.) A compound salt.

ALEU′RON. (From αλεω, to grind.) Meal.

ALEXANDERS. See *Smyrnium olusatrum.*

Alexanders, round-leaved. See *Smyrnium perfoliatum.*

ALEXA′NDRIA. (*Alexandria.*) *Alexandrina.* The bay-tree, or laurel, of Alexandria.

ALEXA′NDRIUM. *Emplastrum virile.* A plaster described by Celsus, made with wax, alum, &c.

ALEXICA′CUM. (From αλεξω, to drive away, and κακον, evil.) An antidote or amulet, to resist poison.

ALEXIPHA′RMIC. (*Alexipharmicum*; from αλεξω to expel, and φαρμακον, a poison.) *Antipharmicum; Caco-alexiteria.* A medicine supposed to preserve the body against the power of poisons, or to correct or expel those taken. The ancients attributed this property to some vegetables and even waters distilled from them. The term, however, is now very seldom used.

ALEXIPYRE′TICUM. (From αλεξω, to drive away, and ϖυρετος, fever.) A febrifuge.

ALEXIPY′RETOS. *Alexipyretum.* A remedy for a fever.

ALE′XIR. An elixir.

ALEXITE′RIUM. (*Alexiterium, i. n.*; from αλεξω, to expel, and τηρεω, to preserve.) A preservative medicine against poison, or contagion.

ALFA′CTA. Distillation.

A′LFADAS. *Alfides.* Cerusse.

ALFA′SRA. *Alphesara.* Arabic terms for the vine.

ALFA′TIDE. Sal ammoniac.

A′LFOL. Sal ammoniac.

A′LFUSA. Tutty.

ALGA. A sea weed.

ALGÆ. 1. The name of an *order* or division of the class *Cryptogamia* in the Linnæan system of plants. The name of one of the seven *families* or natural tribes into which the whole vegetable kingdom is divided by Linnæus in his Philosophia Botanica. He defines them plants, the roots, leaves, and stems of which are all in one. Under this description are comprehended all the sea-weeds and some other aquatic plants.

2. In the sexual system of plants *Algæ* constitute the third *order* of the class, Cryptogamia. From their admitting of little distinction of root, leaf, or stem, and the parts of their flowers being equally incapable of description, the genera are distinguished by the situation of what is supposed to be the flowers or seeds, or by the resemblance which the whole plant bears to some other substance.

The parts of fructification of the algæ are in *calycules* of which there are three varieties:—

1. *Pelta*, target; a flat, oblong fruit, seen in the *Lichen caninus.*

2. *Scutella*, the saucer; a round, hollow, or flat fruit, as in *Lichen stellaris.*

3. *Tuberculum*, the tubercle; an hemispherical fruit, observable in *Lichen geographicus.*

In the fuci, the parts of fructification are sometimes in hollow bladders; and in some of the ulvæ, it is dispersed through the whole substance of the plant.

A′LGALI. A catheter. Also nitre.

A′LGARAH. See *Anchilops.*

A′LGAROTH. (So called from Victorious Algaroth, a physician of Verona, and its inventor.) *Algarot; Algaroth; Mercurius vitæ; Pulvis Algarothi; Pulvis angelicus; Mercurius mortis.* The antimonial part of the butter of antimony, separated from some of its acid by washing it in water. It is violently emetic in doses of two or three grains, and is preferred by many for making the emetic tartar.

ALGE′DO. (From αλγος, pain.) A violent pain about the anus, perinæum, testes, urethra, and bladder, arising from the sudden stoppage of a virulent gonorrhœa. A term very seldom used.

ALGE′MA. (From αλγεω, to be in pain.) *Algemodes; Algematodes.* Uneasiness; pain of any kind.

ALGE'RIÆ. *Algirie.* Lime.

A'LGEROTH. See *Algaroth.*

A'LGIBIC. Sulphur vivum.

A'LGOR. A sudden chillness or rigor.

ALGOSAREL. The Arabian term for the wild carrot. See *Daucus sylvestris.*

ALGUADA. A white leprous eruption.

ALHA'GI. (Arabian.) A species of *Hedysarum.* The leaves are hot and pungent, the flowers purgative.

ALHA'NDALA. An Arabian name for the colocynth, or bitter apple.

ALHA'SEF. (Arabian.) *Alhasaf.* A sort of fœtid pustule, called also *Hydroa.*

A'LIA SQUILLA. (From αλιος, belonging to the sea, and σκιλλα, a shrimp.) The prawn. A species of the genus *cancer.*

A'LICA. (From *alo,* to nourish.) In general signification, a grain, a sort of food admired by the ancients. It is not certain whether it is a grain or a preparation of some kind thereof.

ALICASTRUM. (From *alica,* as *siliquastrum* from *siliqua.*) A kind of bread mentioned by Celsus.

A'LICES. (From αλιζω, to sprinkle.) Little red spots in the skin, which precede the eruption of pustules in the small-pox.

ALIENA'TIO MENTIS. Estrangement of the mind.

ALIENA'TION. (*Alienatio;* from *alieno,* to estrange.) A term applied to any wandering of the mind.

ALIENA'TUS. Alienated. A leaf is so termed when the first leaves give way to others totally different from them, and the natural habit of the genus, as is the case in many of the *mimosæ* from New Holland.

ALIFO'RMIS. Alæform or wing-like. A name given by anatomists and naturalists to some parts from their supposed resemblance, as aliform muscles, &c. See *Alæformis.*

ALIMENT. (*Alimentum;* from *alo,* to nourish.) The name of aliment is given generally to every substance, which being subjected to the action of the organs of digestion, is capable by itself of affording nourishment. In this sense an aliment is extracted necessarily from vegetables or animals: for only those bodies that have possessed life are capable of serving usefully in the nutrition of animals during a certain time. This manner of regarding aliments appears rather too confined. Why refuse the name of aliments to substances which, in reality, cannot of themselves afford nourishment, but which contribute efficaciously to nutrition, since they enter into the composition of the organs, and of the animal fluids? Such are the muriate of soda, the oxyde of iron, silicia, and particularly water, which is found in such abundance in the bodies of animals, and is so necessary to them. It appears preferable to consider as an aliment every substance which can serve in nutrition; establishing, however, the important distinction between substances which can nourish of themselves, and those which are useful to nutrition only in concert with the former.

In respect to their nature, aliments are different from each other, by the proximate principles which predominate in their composition. They may be distinguished into nine classes:—

1st, Farinaceous aliments: wheat, barley, oats, rice, rye, maize, potatoe, sago, salep, peas, haricots, lentils, &c.

2d, Mucilaginous aliments: carrots, salsafy, (goatsbeard,) beet-root, turnip, asparagus, cabbage, lettuce, artichoke, cardoons, pumpoins, melons, &c.

3d, Sweet aliments: the different sorts of sugar, figs, dates, dried grapes, apricots, &c.

4th, Acidulous aliments: oranges, gooseberries, cherries, peaches, strawberries, raspberries, mulberries, grapes, prunes, pears, apples, sorrel, &c.

5th, Fatty and oily aliments: cocoa, olives, sweet almonds, nuts, walnuts, the animal fats, the oils, butter, &c.

6th, Caseous aliments: the different sorts of milk, cheese, &c.

7th, Gelatinous aliments: the tendons, the aponeurosis, the chorion, the cellular membrane, young animals, &c.

8th, Albuminous aliments: the brain, the nerves, eggs, &c.

9th, Fibrinous aliments: the flesh and the blood of different animals.

We might add to this list a great number of substances that are employed as medicines, but which doubtless are nutritive, at least in some of their immediate principles: such are manna, tamarinds, the *pulp of cassia,* the extracts and saps of vegetables, the animal or vegetable decoctions.

Amongst aliments there are few employed such as nature presents them; they are generally prepared, and disposed in such a manner as to be suitable for the action of the digestive organs. The preparations which they undergo are infinitely various, according to the sort of aliment, the people, the climates, customs, the degree of civilization: even fashion is not without its influence on the art of preparing aliments.

In the hand of the skilful cook, alimentary substances almost entirely change their nature: —form, consistence, odour, taste, colour, composition, &c., every thing is so modified that it is impossible for the most delicate tastes to recognise the original substance of certain dishes.

The useful object of cookery is to render aliments agreeable to the senses, and of easy digestion; but it rarely stops here: frequently with people advanced in civilization its object is to excite delicate palates, or difficult tastes, or to please vanity. Then, far from being a useful art, it becomes a real scourge, which occasions a great number of diseases, and has frequently brought on premature death.

We understand by *drink,* a liquid which, being introduced into the digestive organs, quenches thirst, and so by this repairs the habitual losses of our fluid humours: the drinks ought to be considered as real aliments.

The drinks are distinguished by their chemical composition:—

1st, Water of different sorts, spring water, river water, water of wells, &c.

2d, The juices and infusions of vegetables and animals, juices of lemon, of gooseberries, whey, tea, coffee, &c.

3d, Fermented liquors: the different sorts of wine, beer, cyder, perry, &c.

4th, The alcoholic liquours: brandy, alcohol, ether, rum, sack, ratafia.

ALIMENTARY. *Alimentarius.* Nourishing or belonging to food.

ALIMENTARY CANAL. *Canalis alimentarius.* Alimentary duct. A name given to the whole of those passages which the food passes through from the mouth to the anus. This duct may be said to be the true characteristic of an animal; there being no animal without it, and whatever has it, being properly ranged under the class of animals. Plants receive their nourishment by the numerous fibres of their roots, but have no common receptacle for digesting the food received, or for carrying off the excrements. But in all, even the lowest degree of animal life, we may observe a stomach, if not also intestines, even where we cannot perceive the least formation of any organs of the senses, unless that common one of feeling, as in oysters.

ALIMENTARY DUCT. 1. The alimentary canal. See *Alimentary canal.*

2. The thoracic duct is sometimes so called. See *Thoracic duct.*

ALIMOS. Common liquorice.

A′LIMUM. A species of arum.

ALINDE′SIS. (Αλινδησις; from *αλινδουμαι*, to be turned about.) A bodily exercise, which seems to be rolling on the ground, or rather in the dust, after being anointed with oil. Hippocrates says it hath nearly the same effect as wrestling.

ALIPÆ′NOS. (From *α*, neg. and *λιπαινω*, to be fat.) *Alipænum; Alipantos.* An external remedy, without fat or moisture.

ALIPA′SMA. (From *αλειφω*, to anoint.) An ointment rubbed upon the body, to prevent sweating.

ALIPE. Remedies for wounds in the cheek, to prevent inflammation.

ALIPOW. A species of turbith, found near Mount Ceti, in Languedoc. It is a powerful purgative, used instead of senna, but is much more active.

ALI′PTÆ. (From *αλειφω*, to anoint.) Those who anointed persons after bathing.

Alisanders. The same as alexanders.

ALI′SMA. (*Alisma;* from *αλς*, the sea.) The name of a genus of plants in the Linnæan system. Class, *Hexandria;* Order, *Polygynia.* Water-plantain.

ALISMA PLANTAGO AQUATICA. The systematic name of the water plantain, now fallen into disuse.

ALI′STELIS. (From *αλς*, the sea,) Sal Ammoniac.

A′LIT. *Alith.* Asafœtida.

ALKAFI′AL. Antimony.

A′LKAHAT GLAUBE′RI. An alkaline salt.

A′LKAHEST. An imaginary universal menstruum, or solvent. See *Alcahest.*

A′LKAHEST GLAUBE′RI. An alkaline salt.

ALKALESCENT. *Alkalescens.* Any substance in which alkaline properties are beginning to be developed, or to predominate, is so termed.

A′LKALI. (*Alcali*, in Arabic, signifies burnt; or from *al* and *kali*, i. e. the essence, or the whole of kali, the plant from which it was originally prepared, though now derived from plants of every kind.) *Alcali; alifi; alafor; alafort, calcadis.*

Alkalies may be defined, those bodies which combine with acids, so as to neutralise or impair their activity, and produce salts. Acidity and alkalinity are therefore two correlative terms of one species of combination. When Lavoisier introduced oxygen as the acidifying principle, Morveau proposed hydrogen as the alkalifying principle, from its being a constituent of volatile alkali or ammonia. But the splendid discovery by Sir H. Davy, of the metallic basis of potassa and soda, and of their conversion into alkalies, by combination with oxygen, has banished for ever that hypothetical conceit. It is the mode in which the constituents are combined, rather than the nature of the constituents themselves, which gives rise to the acid or alkaline condition. Some metals combined with oxygen in one proportion, produce a body possessed of alkaline properties; in another proportion, of acid properties. And on the other hand, ammonia and prussic acid prove that both the alkaline and acid conditions can exist independent of oxygen. These observations, by generalising our notions of acids and alkalies, have rendered the definitions of them very imperfect. The difficulty of tracing a limit between the acids and alkalies is still increased, when we find a body sometimes performing the functions of an acid, sometimes of an alkali. Nor can we diminish this difficulty by having recourse to the beautiful law discovered by Sir H. Davy, that oxygen and acids go to the positive pole, and hydrogen alkalies, and inflammable bases to the negative pole. We cannot in fact give the name of acid to all the bodies which go to the first of these poles, and that of alkali to those that go to the second; and if we wished to define the alkalies by bringing into view their electric energy, it would be necessary to compare them with the electric energy which is opposite to them. Thus we are always reduced to define alkalinity by the property which it has of saturating acidity, because alkalinity and acidity are two correlative and inseparable terms. M. Gay Lussac conceives the alkalinity which the metallic oxides enjoy, to be the result of two opposite properties, the alkalifying property of the metal, and the acidifying of oxygen, modified both by the combination and by the proportions.

The alkalies may be arranged into three classes: 1st, Those which consist of a metallic basis combined with oxygen. These are three in number, potassa, soda, and lithia. 2d, That which contains no oxygen, viz. ammonia. 3d, Those containing oxygen, hydrogen, and carbon. In this class we have aconita, atropia, brucia, cicuta, datura, delphia, hyosciama, morphia, strychnia, and perhaps some other *truly vegetable* alkalies. The order of vegetable alkalies may be as numerous as that of vegetable acids. The earths, lime, barytes, and strontites, were enrolled among the alkalies by Fourcroy, but they have been kept apart by other systematic writers, and are called alkaline earths.

Besides neutralising acidity, and thereby giving birth to salts, the first four alkalies having the following properties:—

1st, They change the purple colour of many vegetables to a green, the reds to a purple, and the yellows to a brown. If the purple have been reddened by acid, alkalies restore the purple.

2d, They possess this power on vegetable colours *after* being saturated with carbonic acid, by which criterion they are distinguishable from the alkaline earths.

3d, They have an acrid and urinous taste.

4th, They are powerful solvents or corrosives of animal matter; with which as well as with oils in general, they combine, so as to produce neutrality.

5th, They are decomposed, or volatilised, at a strong red heat.

6th, They combine with water in every proportion, and also largely with alcohol.

7th, They continue to be soluble in water when neutralised with carbonic acid; while the alkaline earths thus become insoluble.

It is needless to detail at length Dr. Murray's speculations on alkalinity. They seem to flow from a partial view of chemical phenomena. According to him, either oxygen or hydrogen may generate alkalinity, but the combination of both principles is necessary to give this condition its utmost energy. "Thus the class of alkalies will exhibit the same relations as the class of acids. Some are compounds of a base with oxygen; such are the greater number of the metallic oxydes, and probably of the earths.

Ammonia is a compound of a base with hydrogen. Potassa, soda, barytes, strontites, and probably lime, are compounds of bases with oxygen and hydrogen; and these last, like the analogous order among the acids, possess the highest power." Now, perfectly dry and caustic barytes, lime, and strontites, as well as the dry potassa and soda obtained by Gay Lussac and Thenard, are not inferior in alkaline power to the same bodies after they are slacked or combined with water. 100 parts of lime destitute of hydrogen, that is, pure oxyde of calcium, neutralise 78 parts of carbonic acid. But 132 parts of Dr. Murray's *strongest* lime, that it is the hydrate, are required to produce the same alkaline effect. If we ignite nitrate of barytes, we obtain as is well known, a perfectly dry barytes, or protoxyde of barium; but if we ignite crystallised barytes, we obtain the same alkaline earth combined with a prime equivalent of water. These two different states of barytes were demonstrated by M. Berthollet in an excellent paper published in the 2d volume of the Memoirs D'Arcueil, so far back as 1809. "The first barytes," (that from crystallised barytes,) says he, "presents all the characters of a combination; it is engaged with a substance which *diminishes* its action on other bodies, which renders it more fusible, and which gives it by fusion the appearance of glass. This substance is nothing else but water; but in fact, by adding a little water to the second barytes (that from ignited nitrate,) and by urging it at the fire, we give it the properties of the first." Page 47. 100 parts of barytes void of hydrogen, or dry barytes, neutralise 28½ of dry carbonic acid. Whereas 111⅔ parts of the hydrate, or what Dr. Murray has styled the most energetic, are required to produce the same effect. In fact, it is not hydrogen which combines with the pure barytic earth, but hydrogen and oxygen in the state of water. The proof of this is, that when carbonic acid and that hydrate unite, the exact quantity of water is disengaged. The protoxyde of barium, or pure barytes, has never been combined with hydrogen by any chemist.—*Ure's Chem. Dict.*

ALKALI CAUSTICUM. Caustic alkali. An alkali is so called when deprived of the carbonic acid it usually contains, for it then becomes more caustic, and more violent in its action.

Alkali, caustic volatile. See *Ammonia.*

Alkali, phlogisticated. Prussian alkali. When a fixed alkali is ignited with bullock's blood or other animal substances and lixiviated, it is found to be in a great measure saturated with prussic acid: from the theories formerly adopted respecting this combination, it was called phlogisticated alkali.

ALKALI FIXUM. Fixed alkali. Those alkalies are so called that emit no characteristic smell, and cannot be volatilised, but with the greatest difficulty. Two kinds of fixed alkalies have only hitherto been made known, namely, potassa and soda. See *Potassa* and *Soda.*

Alkali, fossile. See *Soda.*

Alkali, mineral. See *Soda.*

Alkali, Prussian. See *Alkali, phlogisticated.*

Alkali, vegetable. See *Potassa.*

Alkali, volatile. See *Ammonia.*

ALKALI'NA. Alkalines. A class of substances described by Cullen as comprehending the substances otherwise termed *antacida.* They consist of alkalies, and other substances which neutralise acids. The principal alkalines in use, are the carbonates and subcarbonates of soda and potassa, the subcarbonate of ammonia, lime-water, chalk, magnesia and its carbonate.

ALKALIZATION. *Alkalizatio.* The impregnating any thing with an alkaline salt, as spirit of wine, &c.

ALKALOMETER. The name of an instrument for determining the quantity of alkali in commercial potassa and soda.

A'LKANET. (*Alkanah,* a reed, Arabian.) See *Anchusa tinctoria.*

ALKA'NNA. See *Anchusa.*

ALKA'NNA VE'RA. See *Lawsonia inermis.*

A'LKANT. Quicksilver.

ALKA'NTHUM. Arsenic.

ALKASA. A crucible.

ALKEKE'NGI. (Arabian.) The winter-cherry. See *Physalis alkekengi.*

ALKE'RMES. A term borrowed from the Arabs, denoting a celebrated remedy, of the form and consistence of a confection, whereof the kermes is the basis. See *Kermes.*

ALKE'RVA. (Arabian.) Castor oil.

A'LKI PLUMBI. Supposed to be the sugar or acetate of lead.

ALKIMA. See *Alchemy.*

A'LKOHOL. (An Arabian word, which signifies antimony: so called from the usage of the Eastern ladies to paint their eyebrows with antimony, reduced to a most subtle powder; whence it at last came to signify any thing exalted to its highest perfection.) *Alcohol; Alkol; Spiritus vinosus rectificatus; Spiritus vini rectificatus; spiritus vini concentratus; Spiritus vini rectificatissimus.*

1. This term is applied in strictness only to the pure spirit obtainable by distillation and subsequent rectification from all liquids that have undergone vinous fermentation, and from none but such as are susceptible of it. But it is commonly used to signify this *spirit* more or less imperfectly freed from water, in the state in which it is usually met with in the shops, and in which, as it was first obtained from the juice of the grape, it was long distinguished by the name of spirit of wine. At present it is extracted chiefly from grain or melasses in Europe, and from the juice of the sugar cane in the West Indies; and in the diluted state in which it commonly occurs in trade, constitutes the basis of the several spirituous liquors called brandy, rum, gin, whisky, and cordials, however variously denominated or disguised.

As we are not able to compound alkohol immediately from its ultimate constituents, we have recourse to the process of fermentation, by which its principles are first extricated from the substances in which they were combined, and then united into a new compound; to distillation, by which this new compound, the alkohol, is separated in a state of dilution with water, and contaminated with essential oil; and to rectification, by which it is ultimately freed from these.

It appears to be essential to the fermentation of alkohol, that the fermenting fluid should contain saccharine matter, which is indispensable to that species of fermentation called vinous. In France, where a great deal of wine is made, particularly at the commencement of the vintage, that is too weak to be a saleable commodity, it is a common practice to subject this wine to distillation, in order to draw off the spirit; and as the essential oil that rises in this process is of a more pleasant flavour than that of malt or melasses, the French brandies are preferred to any other; though even in the flavour of these there is a difference, according to the wine from which they are produced. In the West Indies a spirit is obtained from the juice of the sugar-cane, which is highly impregnated with its essential oil, and well known by the name of *rum.* The distillers in this country use grain, or melasses, whence they distinguish the products by the name of *malt spirits*, and *melasses spirits.* It is said that a very good spirit may be extracted from the husks of gooseberries or currants, after wine has been made from them.

As the process of malting develops the saccharine principle of grain, it would appear to render it fitter for the purpose; though it is the common practice to use about three parts of raw grain with one of malt. For this two reasons may be assigned: by using raw grain, the expense of malting is saved, as well as the duty on malt; and the process of malting requires some nicety of attention, since, if it be carried too far, part of the saccharine matter is lost, and if it be stopped too soon, this matter will not be wholly developed. Besides, if the malt be dried too quickly, or by an unequal heat, the spirit it yields will be less in quantity, and more unpleasant in flavour. Another object of economical consideration is, what grain will afford the most spirit in proportion to its price, as well as the best in quality. Barley appears to produce less spirit than wheat; and if three parts of raw wheat be mixed with one of malted barley, the produce is said to be particularly fine. This is the practice of the distillers in Holland for producing a spirit of the finest quality; but in England they are expressly prohibited from using more than one part of wheat to two of other grain. Rye, however, affords still more spirit than wheat.

Other articles have been employed, though not generally, for the fabrication of spirit, as carrots and potatoes; and we are lately informed by Professor Proust, that from the fruit of the carob tree he has obtained good brandy in the proportion of a pint from five pounds of the dried fruit.

To obtain pure alcohol, different processes have been recommended; but the purest rectified spirit obtained as above described, being that which is least contaminated with foreign matter, should be employed. Rouelle recommends to draw off half the spirit in a water bath; to rectify this twice more, drawing off two-thirds each time; to add water to this alcohol, which will turn it milky by separating the essential oil remaining in it; to distil the spirit from this water; and finally rectify it by one more distillation.

Baumé sets apart the first running, when about a fourth is come over, and continues the distillation till he has drawn off about as much more, or till the liquor runs off milky. The last running he puts into the still again, and mixes the first half of what comes over with the preceding first product. This process is again repeated, and all the first products being mixed together, are distilled afresh. When about half the liquor is come over, this is to be set apart as pure alcohol.

Alcohol in this state, however, is not so pure as when, to use the language of the old chemists, it has been *dephlegmated*, or still further freed from water, by means of some alkaline salt. Boerhaave recommended, for this purpose, the muriate of soda, deprived of its water of crystallisation by heat, and added hot to the spirit. But the subcarbonate of potassa is preferable. About a third of the weight of the alcohol should be added to it in a glass vessel, well shaken, and then suffered to subside. The salt will be moistened by the water absorbed from the alkohol; which being decanted, more of the salt is to be added, and this is to be continued till the salt falls dry to the bottom of the vessel. The alkohol in this state will be reddened by a portion of the pure potassa, which it will hold in solution, from which it must be freed by distillation in a water bath. Dry muriate of lime may be substituted advantageously for the alkali.

As alkohol is much lighter than water, its specific gravity is adopted as the test of its purity. Fourcroy considers it as rectified to the highest point when its specific gravity is 829, that of water being 1000; and perhaps this is nearly as far as it can be carried by the process of Rouelle or Baumé simply. Borics found the first measure that came over from twenty of spirit at 836 to be 820, at the temperature of 71° F. Sir Charles Blagden, by the addition of alkali, brought it to 813, at 60° F. Chaussier professes to have reduced it to 798; but he gives 998.35 as the specific gravity of water. Lowitz asserts that he has obtained it at 791, by adding as much alkali as nearly to absorb the spirit; but the temperature is not indicated. In the shops, it is about 835 or 840: according to the London College it should be 815.

It is by no means an easy undertaking to determine the strength or relative value of spirits, even with sufficient accuracy for commercial purposes. The following requisites must be obtained before this can be well done: the specific gravity of a certain number of mixtures of alcohol and water must be taken so near each other, as that the intermediate specific gravities may not perceptibly differ from those deduced from the supposition of a mere mixture of the fluids; the expansions or variations of specific gravity in these mixtures must be determined at different temperatures; some easy method must be contrived of determining the presence and quantity of saccharine or oleaginous matter which the spirit may hold in solution, and the effect of such solution on the specific gravity; and lastly, the specific gravity of the fluid must be ascertained by a proper floating instrument with a graduated stem or set of weights; or, which may be more convenient, with both.

The most remarkable characteristic property of alcohol, is its solubility or combination in all proportions with water; a property possessed by no other combustible substance, except the acetic spirit obtained by distilling the dry acetates. When it is burned in a chimney which communicates with the worm-pipe of a distilling apparatus, the product, which is condensed, is found to consist of water, which exceeds the spirit in weight about one-eighth part; or more accurately, 100 parts of alkohol, by combustion, yield 136 of water. If alcohol be burned in closed vessels with vital air, the product is found to be water and carbonic acid. Whence it is inferred that alkohol consists of hydrogen, united either to carbonic acid, or its acidifiable base; and that the oxygen uniting on the one part with the hydrogen, forms water; and on the other with the base of the carbonic acid, forms that acid.

The most exact experiments on this subject are those recently made by De Saussure. The alkohol he used had, at 62.8°, a specific gravity of 0.8302; and by Richter's proportions, it consists of 13.8 water, and 86.2 of absolute alcohol. The vapour of alcohol was made to traverse a narrow porcelain tube, ignited; from which the products passed along a glass tube about six feet in length, refrigerated by ice. A little charcoal was deposited in the porcelain, and a trace of oil in the glass tube. The resulting gas being analysed in an exploding eudiometer, with oxygen, was found to resolve itself into carbonic acid and water. Three volumes of oxygen disappeared for every two volumes of carbonic acid produced; a proportion which obtains in the analysis by oxygenation of olefiant gas. Now, as nothing resulted but a combustible gas of this peculiar constitution, and condensed water equal to 1000-4064 of the original weight of the alkohol, we may conclude that vapour of water and olefiant gas are the sole constituents of alkohol. Subtracting the 13.8 per cent. of water in the alkohol at the beginning of the experiment, the absolute alkohol of Richter will consist of 13.7 hydrogen, 51.98 carbon, and 34.32 oxygen. Hence Gay Lussac infers, that alkohol, in vapour, is composed of one volume olefiant gas, and one volume of the vapour of water, condensed by chemical affinity into one volume.

The sp. gr. of olefiant gas is 0.97804
Of aqueous vapour is 0.62500

Sum = 1.60304
And alkoholic vapour is = 1.6133

These numbers approach nearly to those which would result from two prime equivalents of olefiant gas, combined with one of water; or ultimately, three of hydrogen, two of carbon, and one of oxygen.

The mutual action between alkohol and acids produces a light, volatile, and inflammable substance, called ether. Pure alkalies unite with spirit of wine, and form alkaline tinctures. Few of the neutral salts unite with this fluid, except such as contain ammonia. The carbonated fixed alkalies are not soluble in it. From the strong attraction which exists between alkohol and water, it unites with this last in saline solutions, and in most cases precipitates the salt. This is a pleasing experiment, which never fails to surprise those who are unacquainted with chemical effects. If, for example, a saturated solution of nitre in water be taken, and an equal quantity of strong spirit of wine be poured upon it, the mixture will constitute a weaker spirit, which is incapable of holding the nitre in solution; it therefore falls to the bottom instantly, in the form of minute crystals.

The degree of solubility of many neutral salts in alkohol have been ascertained by experiments made by Macquer, of which an account is published in the Memoirs of the Turin Academy.

All deliquescent salts are soluble in alkohol. Alkohol holding the strontitic salts in solution, gives a flame of a rich purple. The cupreous salts and boracic acid give a green; the soluble calcareous, a reddish; the barytic, a yellowish.

The alkohol of 0.825 has been subjected to a cold of — 91° without congealing.

When potassium and sodium are put in contact with the strongest alkohol, hydrogen is evolved. When chlorine is made to pass through alkohol in a Woolfe's apparatus, there is a mutual action. Water, an oily-looking substance, muriatic acid, a little carbonic acid, and carbonaceous matter, are the products. This oily substance does not redden turnsole, though its analysis by heat shows it to contain muriatic acid. It is white, denser than water, has a cooling taste analogous to mint, and a peculiar, but not ethereous odour. It is very soluble in alkohol, but scarcely in water. The strongest alkalies hardly operate on it.

It was at one time maintained, that alkohol did not exist in wines, but was generated and evolved by the heat of distillation. On this subject Gay Lussac made some decisive experiments. He agitated wine with litharge in fine powder, till the liquid became as limpid as water, and then saturated it with subcarbonate of potassa. The alkohol immediately separated and floated on the top. He distilled another portion of wine *in vacuo*, at 59° Fahr. a temperature considerably below that of fermentation. Alkohol came over. Mr. Brande proved the same position by saturating wine with subacetate of lead, and adding potassa.

Adem and Duportal have substituted for the redistillations used in converting wine or beer into alkohol, a single process of great elegance. From the capital of the still a tube is led into a large copper recipient. This is joined by a second tube to a second recipient, and so on through a series of four vessels, arranged like a Woolfe's apparatus. The last vessel communicates with the worm of the first refrigeratory. This, the body of the still, and the two recipients nearest it, are charged with the wine or fermented liquor. When ebullition takes place in the still, the vapour issuing from it communicates soon the boiling temperature to the liquor in the two recipients. From these the volatilised alkohol will rise and pass into the third vessel, which is empty. After communicating a certain heat to it, a portion of the finer or less condensable spirit will pass into the fourth, and thence, in a little, into the worm of the first refrigeratory. The wine round the worm will likewise acquire heat, but more slowly. The vapour that in that event may pass uncondensed through the first worm, is conducted into a second, surrounded with cold water. Whenever the still is worked off, it is replenished by a stopcock from the nearest recipient, which, in its turn, is filled from the second, and the second from the first worm tub. It is evident, from this arrangement, that by keeping the third and fourth recipients at a certain temperature, we may cause alkohol, of any degree of lightness, to form directly at the remote extremity of the apparatus. The utmost economy of fuel and time is also secured, and a better flavoured spirit is obtained. The *arrière gout* of bad spirit can scarcely be destroyed by infusion with charcoal and redistillation. In this mode of operating, the taste and smell are excellent, from the first. Several stills on the above principle have been constructed at Glasgow for the West India distillers, and have been found extremely advantageous. The excise laws do not permit their employment in the home trade.

If sulphur in sublimation meet with the vapour of alkohol, a very small portion combines with it, which communicates a hydrosulphurous smell to the fluid. The increased surface of the two substances appears to favour the combination. It had been supposed, that this was the only way in which they could be united; but Favre has lately asserted, that having digested two drams of flowers of sulphur in an ounce of alkohol, over a gentle fire not sufficient to make it boil, for twelve hours, he obtained a solution that gave twenty-three grains of precipitate. A similar mixture left to stand for a month in a place exposed to the solar rays, afforded sixteen grains of precipitate; and another from which the light was excluded, gave thirteen grains. If alkohol be boiled with one-fourth of its weight of sulphur for an hour, and filtered hot, a small quantity of minute crystals will be deposited on cooling; and the clear fluid will assume an opaline hue on being diluted with an equal quantity of water, in which state it will pass the filter, nor will any sediment be deposited for several hours. The alkohol used in the last-mentioned experiment did not exceed 840.

Phosphorus is sparingly soluble in alkohol, but in greater quantity by heat than in cold. The addition of water to this solution affords an opaque milky fluid, which becomes clear by the subsidence of the phosphorus.

Earths seem to have scarcely any action upon alkohol. Quicklime, however, produces some alteration in this fluid, by changing its flavour, and rendering it of a yellow colour. A portion is probably taken up.

Soaps are dissolved with great facility in alkohol, with which they combine more readily than with water. None of the metals, or their oxydes, are acted upon by this fluid. Resins, essential oils, camphor, bitumen, and various other substances, are dissolved with great facility in alkohol, from which they may be precipitated by the addition of water. From its property of dissolving resins, it becomes the menstruum of some varnishes.

Camphor is not only extremely soluble in alkohol, but assists the solution of resins in it. Fixed oils, when rendered drying by metallic oxydes, are soluble in it, as well as when combined with alkalies.

Wax, spermaceti, biliary calculi, urea, and all the animal substances of a resinous nature, are soluble in alkohol; but it curdles milk, coagulates albumen, and hardens the muscular fibre and coagulum of the blood.

The uses of alkohol are various. As a solvent of resinous substances and essential oils, it is employed both in pharmacy and by the perfumer. When diluted with an equal quantity of water, constituting what is called proof spirit, it is used for extracting tinctures from vegetable and other substances, the alkohol dissolving the resinous parts, and the water the gummy. From giving a steady heat without smoke when burnt in a lamp, it was formerly much employed to keep water boiling on the tea-table. In thermometers, for measuring great degrees of cold, it is preferable to mercury, as we cannot bring it to freeze. It is in common use for preserving many anatomical preparations, and certain subjects of natural history; but to some it is injurious, the molluscæ for instance, the calcareous covering of which it in time corrodes. It is of considerable use, too, in chemical analysis, as appears under the different articles to which it is applicable.

From the great expansive power of alkohol, it has been made a question, whether it might not be applied with advantage in the working of steam engines. From a series of experiments made by Betancourt, it appears, that the steam of alkohol has, in all cases of equal temperature, more than double the force of that of water; and that the steam of alkohol at 174° F. is equal to that of water 212°: thus there is a considerable diminution of the consumption of fuel, and where this is so expensive as to be an object of great importance, by contriving the machinery so as to prevent the alkohol from being lost, it may possibly at some future time be used with advantage, if some other fluid of great expansive power, and inferior price, be not found more economical.

Alkohol may be decomposed by transmission through a red-hot tube: it is also decomposable by the strong acids, and thus affords that remarkable product, ETHER, and OLEUM VINI.—*Ure's Chem. Dict.*

2. The alkohol of the London Pharmacopœia is directed to be made thus:—Take of rectified spirit, a gallon; subcarbonate of potassa, three pounds. Add a pound of the subcarbonate of potassa, previously heated to 300°, to the spirit, and macerate for twenty-four hours, frequently stirring them; then pour off the spirit, and add to it the rest of the subcarbonate of potassa heated to the same degree; lastly, with the aid of a warm bath, let the alkohol distil over, keep it in a well-stopped bottle. The specific gravity of alkohol is to the specific gravity of distilled water, as 815 to 1,000.

A'LKOSOR. Camphire.

ALKSOAL. A crucible.

ALKYMIA. Powder of basilisk.

A'LLABOR. Lead.

ALLAGITE. A carbosilicate of manganese.

ALLANITE. A mineral, first recognised as a distinct species by Mr. Allan of Edinburgh. It is massive and of a brownish black colour.

ALLANTOI'DES. (From *αλλας*, a hog's pudding, and *ειδος*, likeness: because in some brutal animals it is long and thick.) *Membrana allantoides* A membrane of the fœtus, peculiar to brutes, which contains the urine discharged from the bladder.

ALLELUI'A. (Hebrew. *Praise the Lord.*) So named for its many virtues. See *Oxalis acetosella.*

ALL-GOOD. See *Chenopodium bonushenricus.*

ALL-HEAL. See *Heraclium* and *Stachys.*

ALLIA'CEOUS. (*Alliaceus;* from *allium,* garlick.) Pertaining to garlick.

ALLIA'RIA. (From *allium,* garlick: from its smell resembling garlick.) See *Erysimum alliaria.*

A'LLICAR. Vinegar.

ALLI'COA. Petroleum.

ALLIGATU'RA. A ligature, or bandage.

ALLIO'TICUM. (From *αλλιοω*, to alter, or vary.) An alterative medicine, consisting of various antiscorbutics.—*Galen.*

A'LLIUM. (*Allium, i.* n.; from *oleo,* to smell; because it stinks: or from *αλεω*, to avoid; as being unpleasant to most people.) Garlick.

1. The name of a genus of plants in the Linnæan system. Class, *Hexandria;* Order, *Monogynia.*

2. The pharmacopœial name of garlick. See *Allium sativum.*

ALLIUM CEPA. *Cepa.* *Allium:—scapo nudo inferne ventricoso longiore, foliis teretibus,* of Linnæus. The Onion. Dr. Cullen says, onions are acrid and stimulating, and possess very little nutriment. With bilious constitutions they generally produce flatulency, thirst, head-ache, and febrile symptoms: but where the temperament is phlegmatic, they are of infinite service, by stimulating the habit and promoting the natural secretions, particularly expectoration and urine. They are recommended in scorbutic cases, as possessing antiscorbutic properties. Externally, onions are employed in suppurating poultices, and suppression of urine in children is said to be relieved by applying them, roasted to the pubes.

ALLIUM PORRUM. The Leek or Porret. *Porrum.* Every part of this plant, but more particularly the root, abounds with a peculiar odour. The expressed juice possesses diuretic qualities, and is given in the cure of dropsical diseases, and calculous complaints, asthma, and scurvy. The fresh root is much employed for culinary purposes.

ALLIUM SATIVUM. *Allium; Theriaca rusticorum.* Garlick. *Allium:—caule planifolio bulbifero, bulbo composito, staminibus tricuspidatis,* of Linnæus. This species of garlick, according to Linnæus, grows spontaneously in Sicily; but, as it is much employed for culinary and medicinal purposes, it has been long very generally cultivated in gardens. Every part of the plant, but more especially the root, has a pungent acrimonious taste, and a peculiarly offensive strong smell. This odour is extremely penetrating and diffusive; for, on the root being taken into the stomach, the alliaceous scent impregnates the whole system, and is discoverable in the various excretions, as in the urine, perspiration, milk, &c. Garlick is generally allied to the onion, from which it seems only to differ in being more powerful in its effects, and in its active matter, being in a more fixed state. By stimulating the stomach, they both favour digestion, and, as a stimulus, are readily diffused over the system. They may, therefore, be considered as useful condiments with the food of phlegmatic people, or those whose circulation is languid, and secretions interrupted; but with those subject to inflammatory complaints, or where great irritability prevails, these roots, in their acrid state, may prove very hurtful. The medicinal uses of garlick are various; it has been long in estimation as an expectorant in pituitous asthmas, and other pulmonary affections, *unattended* with inflammation. In hot bilious constitutions, therefore, garlick is improper: for it frequently produces flatulence, head-ache, thirst, heat, and other inflammatory symptoms. A free use of it is said to promote the piles in habits disposed to this complaint. Its utility as a diuretic in dropsies is attested by unquestionable authorities; and its febrifuge power has not only been experienced in preventing the paroxysms of intermittents, but even in subduing the plague. Bergius says quartans have been cured by it; and he begins by giving one bulb, or clove, morning and evening, adding every day one more, till four or five cloves be taken at a dose: if the fever then vanishes, the dose is to be diminished, and it will be sufficient to take one or two cloves, twice a day, for some weeks. Another virtue of garlick is that of an anthelminthic. It has likewise been found of great advantage in scorbutic cases, and in calculous disorders, acting in these not only as a diuretic, but, in several instances, manifesting a lithontriptic power. That the juice of alliaceous plants, in general, has considerable effects upon human calculi, is to be inferred from the experiments of Lobb; and we are abundantly warranted in asserting that a decoction of the beards of leeks, taken liberally, and its use persevered in for a length of time, has been found remarkably successful in calculous and gravelly complaints. The penetrating and diffusive acrimony of garlick, renders its external application useful in many disorders, as a rubefacient, and more especially as applied to the soles of the feet, to cause a revulsion from the head or breast, as was successfully prastised and recommended by Sydenham. As soon as an inflammation appears, the garlick cataplasm should be removed, and one of bread and milk be applied, to obviate excessive pain. Garlick has also been variously employed externally, to tumours and cutaneous diseases: and, in certain cases of deafness, a clove, or small bulb of this root, wrapt in gauze or muslin, and introduced into the meatus auditorius, has been found an efficacious remedy. Garlick may be administered in different forms; swallowing the clove entire, after being dipped in oil, is recommended as the most effectual; where this cannot be done, cutting it into pieces without bruising it, and swallowing these may be found to answer equally well, producing thereby no uneasiness in the fauces. On being beaten up and formed into pills, the active parts of this medicine soon evaporate: this Dr. Woodville, in his Medical Botany, notices, on the authority of Cullen, who thinks that Lewis has fallen into a gross error, in supposing dried garlick more active than fresh. The syrup and oxymel of garlick, which formerly had a place in the British Pharmacopœias, are now expunged. The cloves of garlick are by some bruised, and applied to the wrists, to cure agues, and to the bend of the arm, to cure the toothache: when held in the hand, they are said to relieve hiccough; when beat with common oil into a poultice, they resolve sluggish humours; and, if laid on the navels of children, they are supposed to destroy worms in the intestines.

Allium victoriale. *Victorialis longa.* The root, which when dried loses its alliaceous smell and taste, is said to be efficacious in allaying the abdominal spasms of gravid females.

ALLO'CHOOS. (From *αλλος*, another, and *χεω*, to pour.) Hippocrates uses this word to mean delirious.

ALLOCHROITE. A massive opaque mineral of a grayish, yellowish, or reddish colour.

ALLOEO'SIS. (From *αλλος*, another.) Alteration in the state of a disease.

Alloeo'tica. (From *αλλος*, another.) Alteratives. Medicines which change the appearance of the disease.

ALLOGNO'SIS. (From *αλλος*, another, and *γινωσκω*, to know.) Delirium; perversion of the judgment; incapability of distinguishing persons.

ALLOPHANE. A mineral of a blue, and sometimes a green or brown colour.

ALLO'PHASIS. (From *αλλος*, another, and *φαω*, to speak.) According to Hippocrates, a delirium, where the patient is not able to distinguish one thing from another.

ALLOTRIOPHA'GIA. (From *αλλοτριος*, foreign, and *φαγω*, to eat.) In Vogel's Nosology, it signifies the greedily eating unusual things for food. See *Pica.*

ALLOY. Allay. 1. Where any precious metal is mixed with another of less value, the assayers call the latter the alloy, and do not in general consider it in any other point of view than as debasing or diminishing the value of the precious metal.

2. Philosophical chemists have availed themselves of this term to distinguish all metallic compounds in general. Thus brass is called an alloy of copper and zinc; bell metal an alloy of copper and tin.

Every alloy is distinguished by the metal which predominates in its composition, or which gives it its value. Thus English jewellery trinkets are ranked under alloys of gold, though most of them deserve to be placed under the head of copper. When mercury is one of the component metals, the alloy is called *amalgam.* Thus we have an amalgam of gold, silver, tin, &c. Since there are about thirty different permanent metals, independent of those evanescent ones that constitute the bases of the alkalies and earths, there ought to be about 870 different species of binary alloy. But only 132 species have been hitherto made and examined. Some metals have so little affinity for others, that as yet no compound of them has been effected, whatever pains have been taken. Most of these obstacles to alloying, arise from the difference in fusibility and volatility. Yet a few metals, the melting point of which is nearly the same, refuse to unite. It is obvious that two bodies will not combine, unless their affinity or reciprocal attraction be stronger than the cohesive attraction of their individual particles. To overcome this cohesion of the solid bodies, and render affinity predominant, they must be penetrated by caloric. If one be very difficult of fusion, and the other very volatile, they will not unite unless the reciprocal attraction be exceedingly strong. But if their degree of fusibility be almost the same, they are easily placed in the circumstances most favourable for making an alloy. If we are therefore far from knowing all the binary alloys which are possible, we are still further removed from knowing all the triple, quadruple, &c. which may exist. It must be confessed, moreover, that this department of chemistry has been imperfectly cultivated.

Besides, alloys are not, as far as we know, definitely regulated like oxydes in the proportions of their component parts. 100 parts of mercury will combine with 4 or 8 parts of oxygen, to form two distinct oxydes, the black and the red; but with no greater, less, or intermediate proportions. But 100 parts of mercury will unite with 1, 2, 3, or with any quantity up to 100 or 1000, of tin or lead. The alloys have the closest relations in their physical properties with the metals. They are all solid at the temperature of the atmosphere, except some amalgams: they possess metallic lustre, even when reduced to a coarse powder: are completely opaque, and more or less dense, according to the metals which compose them; are excellent conductors of electricity; crystallise more or less perfectly; some are brittle, others ductile and malleable; some have a peculiar odour; several are very sonorous and elastic. When an alloy consists of metals differently fusible, it is usually malleable while cold, but brittle while hot; as is exemplified in brass.

The density of an alloy is sometimes greater, sometimes less than the mean density of its components, showing that, at the instant of their union, a diminution or augmentation of volume takes place. The relation between the expansion of the separate metals and that of their alloys, has been investigated only in a very few cases. Alloys containing a volatile metal are decomposed, in whole or in part, at a strong heat. This happens with those of arsenic, mercury, tellurium, and zinc. Those that consist of two differently fusible metals, may often be decomposed by exposing them to a temperature capable of melting only one of them. This operation is called eliquation. It is practised on the great scale to extract silver from copper. The argentiferous copper is melted with $3\frac{1}{2}$ times its weight of lead; and the triple alloy is exposed to a sufficient heat. The lead carries off the silver in its fusion, and leaves the copper under the form of a spongy lump. The silver is afterwards recovered from the lead by another operation.

Some alloys oxydise more readily by heat and air, than when the metals are separately treated. Thus 3 of lead and 1 of tin, at a dull red, burn visibly, and are almost instantly oxydised. Each by itself, in the same circumstances, would oxydise slowly, and without the disengagement of light.

The formation of an alloy must be regulated by the nature of the particular metals.

The degree of affinity between metals may be in some measure estimated by the greater or less facility with which, when of different degrees of fusibility or volatility, they unite, or with which they can after union be separated by heat. The greater or less tendency to separate into different proportional alloys, by long-continued fusion, may also give some information on this subject. Mr. Hatchett remarked, in his admirable researches on metallic alloys, that gold made standard with the usual precautions by silver, copper, lead, antimony, &c. and then cast into vertical bars, was by no means a uniform compound; but that the top of the bar, corresponding to the metal at the bottom of the crucible, contained the larger proportion of gold. Hence, for thorough combination, two red-hot crucibles should be employed; and the liquefied metals should be alternately poured from the one into the other. And to prevent unnecessary oxydisement by exposure to air, the crucibles should contain, besides the metal, a mixture of common salt and pounded charcoal. The melted alloy should also be occasionally stirred up with a rod of pottery.

The most direct evidence of a chemical change having taken place in the two metals by combination, is when the alloy melts at a much lower temperature than the fusing points of its components. Iron, which is nearly infusible, when alloyed with gold acquires almost the fusibility of this metal. Tin and lead form solder, an alloy more fusible than either of its components; but the triple compound of tin, lead, and bismuth, is most remarkable on this account. The analogy is here strong, with the increase of solubility which salts acquire by mixture, as is exemplified in the uncrystallisable residue of saline solutions, or mother waters, as they are called. Sometimes two metals will not directly unite, which yet, by the intervention of a third, are made to combine. This happens with mercury and iron, as has been shown by Messrs. Aikin, who effected this difficult amalgamation by previously uniting the iron to tin or zinc.

The tenacity of alloys is generally, though not always, inferior to the mean of the separate metals. One part of lead will destroy the compactness and tenacity of a thousand of gold. Brass made with a small proportion of zinc, is more ductile than copper itself; but when one-third of zinc enters into its composition, it becomes brittle.

In common cases, the specific gravity affords a good criterion whereby to judge of the proportion in an alloy, consisting of two metals of different densities.—*Ure.*

ALLSPICE. See *Myrtus Pimenta.*

ALLUVIAL. That which is deposited in valleys, or in plains, from neighbouring mountains. Gravel, loam, clay, sand, brown coal, wood coal, bog iron ore, and calc tuff compose the alluvial deposits.

A'LMA. The first motion of a fœtus to free itself from its confinement.

2. Water.—*Rulandus.*

ALMABRI. A stone like Amber.

A'LMAGRA. *Bolum Cuprum.* 1. Red earth, or ochre, used by the ancients as an astringent.

2. Rulandus says it is the same as *Lotio.*

3. In the Theatrum Chymicum, it is a name for the white sulphur of the alchemists.

ALMA'NDA CATHARTICA. A plant growing on the shores of Cayenne and Surinam, used by the inhabitants as a remedy for the colic; supposed to be cathartic.

ALMARA'NDA. *Almakis.* Litharge.

ALMA'RCAB. An Arabian word for Litharge of Silver.

ALMARCA'RIDA. Litharge of Silver.

ALMA'RGEN. *Almarago.* Coral.

ALMARKASI'TA. Mercury.

ALMA'RTAK. Powder of litharge.

ALMATA'TICA. Copper.

ALMEAILE'TU. A word used by Avicenna, to express a preternatural heat less than that of fever, and which may continue after a fever.

ALMECA'SITE. *Almechasite.* Copper.

ALME'NE. Rock salt.

Almi'sa. Musk.

Almiza'dar. Sal Ammoniac.

Almiza'dir. Verdigris.

ALMOND. See *Amygdalus.*

Almond, bitter. See *Amygdalus.*

Almond, sweet. See *Amygdalus.*

Almond paste. This cosmetic for softening the skin and preventing chops, is made of four ounces of blanched bitter almonds, the white of an egg, rose water and rectified spirits, equal parts, as much as is sufficient.

Almonds of the Ears. A popular name for the tonsils, which have been so called from their resemblance to an almond in shape. See *Tonsils.*

Almonds of the Throat. A vulgar name for the tonsils. See *Tonsils.*

Alnabati. In Avicenna and Serapion, this word means the *siliqua dulcis*, a gentle laxative. See *Ceratonia siliqua.*

A'lnec. Tin.

A'lneric. Sulphur vivum.

A'LNUS. (*Alno*, Italian.) The alder. The pharmacopœial name of two plants, sometimes used in medicine, though rarely employed in the present practice.

1. *Alnus rotundifolia; glutinosa; viridis.* The common alder-tree. See *Betula alnus.*

2. *Alnus nigra.* The black or berry-bearing alder. See *Rhamnus Frangula.*

A'LOE. (*Aloë*, *ës.* fr. from *ahlah*, a Hebrew word, signifying growing near the sea.) The name of a genus of plants of the Linnæan system. Class, *Hexandria*; Order, *Monogynia.* The Aloe.

Aloë Caballina. See *Aloë perfoliata.*

Aloë Guineensis. See *Aloë perfoliata.*

Aloe perfoliata. *Aloë Succotorina; Aloë Zocotorina.* Succotorine aloes is obtained from a variety of the *Aloë perfoliata* of Linnæus:—*foliis caulinis dentatis, amplexicaulibus vaginantibus, floribus corymbosis cernuis, pedunculatis subcylindricis.* It is brought over wrapt in skins, from the Island of Socotora, in the Indian Ocean; it is of a bright surface and in some degree pellucid; in the lump of a yellowish red colour, with a purplish cast; when reduced into powder, it is of a golden colour. It is hard and friable in very cold weather; but in summer it softens very easily betwixt the fingers. It is extremely bitter, and also accompanied with an aromatic flavour, but not so much as to cover its disagreeable taste. Its scent is rather agreeable, being somewhat similar to that of myrrh. Of late this sort has been very scarce, and its place in a great measure supplied by another variety, brought from the Cape of Good Hope, which is said to be obtained from the *Aloë spicata* of Linnæus, by inspissating the expressed juice of the leaves, whence it is termed in the London Pharmacopœia *Extractum aloës spicatæ.*

The *Aloë hepatica, vel Barbadensis*, the common or Barbadoes or hepatic aloes, was thought to come from a variety of the *Aloë perfoliata* described:—*floribus pedunculatis, cernuis corymbosis, subcylindricis, foliis spinosis, confertis, dentatis, vaginantibus, planis, maculatis*: but Dr. Smith has announced, that it will be shown in Sibthorp's Flora Græca, to be from a distinct species, the *Aloë vulgaris*, or true *αλοη* of Dioscorides; and it is therefore termed in the London Pharmacopœia, *Aloës vulgaris extractum.* The best is brought from Barbadoes in large gourd-shells; an inferior sort in pots, and the worst in casks. It is darker coloured than the Socotorine, and not so bright; it is also drier and more compact, though sometimes the sort in casks is soft and clammy. To the taste it is intensely bitter and nauseous, being almost wholly without that aroma which is observed in the Socotorine. To the smell it is strong and disagreeable.

The *Aloë caballina, vel Guineensis*, or horse-aloes, is easily distinguished from both the foregoing, by its strong rank smell; in other respects it agrees pretty much with the hepatic, and is now not unfrequently sold in its place. Sometimes it is prepared so pure and bright as scarcely to be distinguishable by the eye, even from the Socotorine, but its offensive smell betrays it; and if this also should be dissipated by art, its wanting the aromatic flavour of the finer aloes will be a sufficient criterion. This aloe is not admitted into the materia medica, and is employed chiefly by farriers.

The general nature of these three kinds is nearly the same. Their particular differences only consist in the different proportions of gum to their resin, and in their flavour. The smell and taste reside principally in the gum, as do the principal virtues of the aloes. Twelve ounces of Barbadoes aloes yield nearly 4 ounces of resin, and 8 of gummy extract. The same quantity of Socotorine aloes yields 3 ounces of resin and 9 of gummy extract.

Aloes is a well-known stimulating purgative, a property which it possesses not only when taken internally, but also by external application. The cathartic quality of aloes does not reside in the resinous part of the drug, but in the gum, for the pure resin has little or no purgative power. Its medium dose is from 5 to 15 grains, nor does a larger quantity operate more effectually. Its operation is exerted on the large intestines; principally on the rectum. In small doses long continued, it often produces much heat and irritation, particularly about the anus, from which it sometimes occasions a bloody discharge; therefore, to those who were subject to piles, or of an hæmorrhagic diathesis, or even in a state of pregnancy, its exhibition has been productive of considerable mischief; but on the contrary, by those of a phlegmatic constitution, or those suffering from uterine obstructions (for the stimulant action of aloes, it has been supposed, may be extended to the uterus,) and in some cases of dyspepsia, palsy, gout, and worms, aloes may be employed as a laxative with peculiar advantage. In all diseases of the bilious tribe, aloes is the strongest purge, and the best preparations for this purpose are the pilula ex aloë cum myrrhâ, the tinctura aloës, or the extractum colocynthidis compositum. Its efficacy in jaundice is very considerable, as it proves a succedaneum to the bile, of which in that disease there is a defective supply to the intestine either in quantity or quality. Aloes therefore may be considered as injurious where inflammation or irritation exist in the bowels or neighbouring parts, in pregnancy, or in habits disposed to piles; but highly serviceable in all hypochondriac affections, cachectic habits, and persons labouring under oppression of the stomach caused by irregularity. Aromatics correct the offensive qualities of aloes the most perfectly. The canella alba answers tolerably, and without any inconvenience; but some rather prefer the essential oils for this purpose. Dr. Cullen says, "If any medicine be entitled to the appellation of a *stomach purge*, it is certainly aloes. It is remarkable with regard to it, that it operates almost to as good a purpose in a small as in a large dose; that one or two grains will produce one considerable dejection, and 20 grains will do no more, except it be that in the last dose the operation will be attended with gripes, &c. Its chief use is to render the peristaltic motion regular, and it is one of the best cures in habitual costiveness. There is a difficulty we meet with in the exhibition of purgatives, viz. that they will not act but in their full dose, and will not produce half their effect if given in half the dose. For this purpose we are chiefly confined to aloes. Neutral salts in half their dose will not have half their effect; although even from these, by large dilution, we may obtain this property; but besides them and our present medicine, I know no other which has any title to it, except sulphur. Aloes sometimes cannot be employed. It has the effect of stimulating the rectum more than other purges, and with justice has been accused of exciting hæmorrhoidal swellings, so that we ought to abstain from it in such cases, except when we want to promote them. Aloes has the effect of rarifying the blood and disposing to hæmorrhagy, and hence it is not recommended in uterine fluxes. Fœtid gums are of the same nature in producing hæmorrhagy, and perhaps this is the foundation of their emmenagogue power.” Aloes is administered either simply in powders, which is too nauseous, or else in composition:—1. With purgatives, as soap, scammony, colocynth, or rhubarb. 2. With aromatics, as canella, ginger, or essential oils. 3. With bitters, as gentian. 4. With emmenagogues, as iron, myrrh, wine, &c. It may be exhibited in pills as the most convenient form, or else dissolved in wine, or diluted alkohol. The officinal preparations of aloes are the following:—

1. Pilulæ Aloës.
2. Pilula Aloës Composita.
3. Pilulæ Aloës cum Assafœtidâ.
4. Pilula Aloës cum Colocynthide.
5. Pilula Aloës cum Myrrha.
6. Tinctura Aloës.
7. Tinctura Aloës Ætherialis.
8. Tinctura Aloës et Myrrha.
9. Vinum Aloës.
10. Extractum Aloës.
11. Decoctum Aloës Compositum.
12. Pulvis Aloës Compositus.
13. Pulvis Aloës cum Canella.
14. Pulvis Aloës cum Guaiaco.
15. Tinctura Aloës Composita.
16. Extractum Colocynthidis Compositum.
17. Tinctura Benzoini Composita.

Aloë Socotorina. See *Aloë perfoliata.*

Aloë Zocotorina. See *Aloë perfoliata.*

ALOEDA'RIA. (From *αλοη*, the aloe.) Compound purging medicines: so called from having aloes as the chief ingredient.

ALOEPHANGINA. Medicines formed by a combination of aloes and aromatics.

ALOES. *Fel naturæ.* The inspissated juice of the aloe plant. Aloes is distinguished into three species, *socotorine*, *hepatic*, and *caballine*; of which the two first are directed for officinal use in our pharmacopœias. See *Aloë perfoliata.*

ALOES LIGNUM. See *Lignum Aloës.*

ALOE'TIC. A medicine wherein aloes is the chief or fundamental ingredient.

ALOGOTRO'PHIA. (From *αλογος*, disproportionate, and *τρεφω*, to nourish.) Unequal nourishment, as in the rickets.

A'LOHAR. (Arabian.) *Alohoc.* Mercury.

ALO'MBA. (Arabian.) *Alooc.* Lead.

ALO'PECES. (From *αλωπηξ*, the fox.) The psoæ muscles are so called by Fallopius and Vesalius, because in the fox they are particularly strong.

ALOPE'CIA. (From *αλωπηξ*, a fox: because the fox is subject to a distemper that resembles it; or, as some say, because the fox's urine will occasion baldness.) Baldness, or the falling off of the hair. A genus of disease in Sauvages' Nosology.

ALOPECUROIDEA. (From *alopecurus*, the fox-tail grass.) Resembling the alopecurus. The name of a division of grasses.

ALO'SA. (From *αλισκω*, to take: because it is ravenous.) See *Clupea alosa.*

ALOSA'NTHI. (From *αλς*, salt, and *ανθος*, a flower.) *Alosanthum.* Flowers of salt.

A'LOSAT. Quicksilver.

ALOSOHOC. Quicksilver.

ALPHABE'TUM CHYMICUM. Raymond Lully hath given the world this alphabet, but to what end is difficult to say:—

A *significat Deum,*
B ——— *Mercurium.*
C ——— *Salis Petram.*
D ——— *Vitriolum.*
E ——— *Menstruale.*
F ——— *Lunam claram.*
G ——— *Mercurium nostrum.*
H ——— *Salem purum.*
I ——— *Compositum Lunæ.*
K ——— *Compositum Solis.*
L ——— *Terram compositi Lunæ.*
M ——— *Aquam compositi Lunæ.*
N ——— *Ærem compositi Lunæ.*
O ——— *Terram compositi Solis.*
P ——— *Aquam compositi Solis.*
Q ——— *Ærem compositi Solis.*
R ——— *Ignem compositi Solis.*
S ——— *Lapidem album.*
T ——— *Medicinam corporis rubei.*
U ——— *Calorem fumi secreti.*
X ——— *Ignem siccum cineris.*
Y ——— *Calorem balnei.*
Z ——— *Separationem liquorum.*
Z ——— *Alembicum cum cucurbitâ.*

A'LPHANIC. *Alphenic.* An Arabian word, signifying tender, for barley-sugar, or sugar-candy.

A'LPHITA. (*Alphita*, the plural of *αλφιτον*, the meal of barley in general.) By Hippocrates this term is applied to barley-meal either toasted or fried. Galen says that *κριμνα* is coarse meal, *αλευρον* is fine meal, and *αλφιτα* is a middling sort.

ALPHI'TIDON. *Alphitedum.* It is when a bone is broken into small fragments like *alphite* or bran.

ALPHO'NSIN. The name of an instrument for extracting balls. It is so called from the name of its inventor, Alphonso Ferrier, a Neapolitan physician. It consists of three branches, which separate from each other by their elasticity, but are capable of being closed by means of a tube in which they are included.

ALPHOSIS. The specific name of a disease in the genus *Epichrosis* of Good's Nosology.

A'LPHUS. (*Αλφος*; from *αλφαινω*, to change: because it changes the colour of the skin.) A species of leprosy, called by the ancients *vitilago*, and which they divided into *alphus*, *melas*, and *leuce*. See *Lepra.*

A'LPINI BALSAMUM. Balm of Gilead.

ALPI'NUS, PROSPER, a Venetian, born in 1553, celebrated for his skill in medicine and botany. After graduating at Padua, he went to Egypt, and during three years carefully studied the plants of that country, and the modes of treating diseases there; of which he afterwards published a very learned account. He has left also some other less important works. He was appointed physician to the celebrated Andrew Doria; and subsequently botanical professor at

Padua, which office he retained till his death in 1616.

A'LRACHAS. Lead.

ALRA'TICA. An Arabic word used by Albucasis, to signify a partial or a total imperforation of the vagina.

ALSA'MACH. An Arabic name for the great hole in the os petrosum.

A'LSINE. (*Alsine, es.* f.; from αλσος, a grove: so called because it grows in great abundance in woods and shady places.) The name of a genus of plants in the Linnæan system. Class, *Pentandria;* Order, *Trigynia.* Chickweed.

ALSINE MEDIA. *Morsus gallinæ centunculus.* The systematic name for the plant, called chickweed, which, if boiled tender, may be eaten like spinach, and forms also an excellent emollient poultice.

ALSTON, CHARLES, born in Scotland in 1683, was early attached to the study of botany, and distinguished himself by opposing the sexual system of Linnæus. He afterwards studied under Boerhaave at Leyden; then returning to his native country, was materially instrumental, in conjunction with the celebrated Alexander Monro, in establishing the medical school at Edinburgh, where he was appointed professor of botany and materia medica. He died in 1760. His "Lectures on the Materia Medica," a posthumous work, abound in curious and useful facts, which will long preserve their reputation.

A'LTAFOR. Camphire.

A'LTERATIVE. (*Alterans;* from *altero,* to change.) Alterative medicines are those remedies which are given with a view to re-establish the healthy functions of the animal economy, without producing any sensible evacution.

ALTERNÆ PLANTÆ. Alternate leaved plants. The name of a class of plants in Sauvages' Methodus foliorum.

ALTERNANS. Alternate; placed alternately. A term applied by botanists to leaves, gems, &c.

ALTERNUS. Alternate. In botany, this term is applied to branches and leaves when they stand singly on each side, in such a manner that between every two on one side there is but one on the opposite side, as on the branches of the *Althæa officinalis, Rhamnus catharticus,* and leaves of the *Malva rotundifolia.*

ALTHÆ'A. (*Althæa, æ.* f.; from αλθεω, to heal: so called from its supposed qualities in healing.) 1. The name of a genus of plants of the Linnæan system. Class, *Monadelphia;* Order, *Polyandria.* Marsh-mallow.

2. The pharmacopœial name of the marsh-mallow. See *Althea Officinalis.*

ALTHÆA OFFICINALIS. The systematic name of the marsh-mallow. *Malvaviscus; Aristalthæa. Althæa:—foliis simplicibus tomentosis.* The mucilaginous matter with which this plant abounds, is the medicinal part of the plant; it is commonly employed for its emollient and demulcent qualities in tickling coughs, hoarseness, and catarrhs, in dysentery, and difficulty and heat of urine. The leaves and root are generally selected for use. They relax the passages in nephritic complaints, in which last case a decoction is the best preparation. Two or three ounces of the fresh roots may be boiled in a sufficient quantity of water to a quart, to which one ounce of gum-arabic may be added. The following is given where it is required that large quantities should be used. An ounce of the dried roots is to be boiled in water, enough to leave two or three pints to be poured off for use: if more of the root be used, the liquor will be disagreeably slimy. If sweetened, by adding a little more of the root of liquorice, it will be very palatable. The root had formerly a place in many of the compounds in the pharmacopœias, but now it is only directed in the form of syrup.

ALTHA'NACA. *Althanacha.* Orpiment.

ALTHEBE'GIUM. An Arabian name for a sort of swelling, such as is observed in cachectic and leuco-phlegmatic habits.

ALTHE'XIS. (From αλθειν, to cure, or heal.) Hippocrates often uses this word to signify the cure of a distemper.

ALTIHIT. So Avicenna calls the *Laserpitium* of the ancients.

A'LUD. Arabian Aloes.

ALUDEL. A hollow sphere of stone, glass, or earthenware, with a short neck projecting at each end, by means of which one globe might be set upon the other. The uppermost has no opening at the top. They were used in former times for the sublimation of several substances.

ALUM. See *Alumen.*

ALUM EARTH. A massive mineral of a blackish brown colour, a dull lustre, an earthy and somewhat slaty fracture, sectile and rather soft, containing charcoal silica, alumina, oxyde of iron, sulphur, sulphates of lime, potassa, and iron, magnesia, muriate of potassa, and water.

ALUM SLATE. A massive mineral of a bluish black colour.

ALU'MEN. (*Alum,* an Arabian word.) *Assos; Azub; Aseb; Elanula; Sulphas aluminæ acidulus cum potassâ; Super-sulphas aluminæ et potassæ; Argilla vitriolata.* Alum. This important salt has been the object of innumerable researches both with regard to its fabrication and composition. It is produced, but in a very small quantity, in the native state; and this is mixed with heterogeneous matters. It effloresces in various forms upon ores during calcination, but it seldom occurs crystallised. The greater part of this salt is factitious, being extracted from minerals called alum ores, such as,

1. Sulphuretted clay. This constitutes the purest of all aluminous ores, namely, that of La Tolfa, near Civita Vecchia, in Italy. It is white, compact, and as hard as indurated clay, whence it is called *petra aluminaris.* It is tasteless and mealy; one hundred parts of this ore contain above forty of sulphur and fifty of clay, a small quantity of potassa, and a little iron. Bergman says it contains forty-three of sulphur in one hundred, thirty-five of clay, and twenty-two of siliceous earth. This ore is first torrefied to acidify the sulphur, which then acts on the clay, and forms the alum.

2. The pyritaceous clay, which is found at Schwemsal, in Saxony, at the depth of ten or twelve feet. It is a black and hard, but brittle substance, consisting of clay, pyrites, and bitumen. It is exposed to the air for two years, by which means the pyrites are decomposed, and the alum is formed. The alum ores of Hesse and Liege are of this kind; but they are first torrefied, which is said to be a disadvantageous method.

3. The schistus aluminaris contains a variable proportion of petroleum and pyrites intimately mixed with it. When the last are in a very large quantity, this ore is rejected as containing too much iron. Professor Bergman very properly suggested, that by adding a proportion of clay, this ore may turn out advantageously for producing alum. But if the petrol be considerable, it must be torrefied. The mines of Becket in Nor-

mandy, and those of Whitby in Yorkshire, are of this species.

4. Volcanic aluminous ore. Such is that of Solfaterra near Naples. It is in the form of a white saline earth, after it has effloresced in the air; or else it is in a stony form.

5. Bituminous alum ore is called shale, and is in the form of a schistus, impregnated with so much oily matter, or bitumen, as to be inflammable. It is found in Sweden, and also in the coal mines at Whitehaven, and elsewhere.

Chaptal has fabricated alum on a large scale from its component parts. For this purpose he constructed a chamber 91 feet long, 48 wide, and 31 high in the middle. The walls are of common masonry, lined with a pretty thick coating of plaster. The floor is paved with bricks, bedded in a mixture of raw and burnt clay; and this pavement is covered with another, the joints of which overlap those of the first, and instead of mortar, the bricks are joined with a cement of equal parts of pitch, turpentine, and wax, which, after having been boiled till it ceases to swell, is used hot. The roof is of wood, but the beams are very close together, and grooved lengthwise, the intermediate space being filled up by planks fitted into the grooves, so that the whole is put together without a nail. Lastly, the whole of the inside is covered with three or four successive coatings of the cement above mentioned, the first being laid on as hot as possible; and the outside of the wooden roof was varnished in the same manner. The purest and whitest clay being made into a paste with water, and formed into balls half a foot in diameter, these are calcined in a furnace, broken to pieces, and a stratum of the fragments laid on the floor. A due proportion of sulphur is then ignited in the chamber, in the same manner as for the fabrication of sulphuric acid; and the fragments of burnt clay, imbibing this as it forms, begin after a few days to crack and open, and exhibit an efflorescence of sulphate of alumina. When the earth has completely effloresced, it is taken out of the chamber, exposed for some time in an open shed, that it may be the more intimately penetrated by the acid, and is then lixiviated and crystallised in the usual manner. The cement answers the purpose of lead on this occasion very effectually, and, according to Chaptal, costs no more than lead would at three farthings a pound.

Curaudau has lately recommended a process for making alum without evaporation. One hundred parts of clay and five of muriate of soda are kneaded into a paste with water, and formed into loaves. With these a reverberatory furnace is filled, and a brisk fire is kept up for two hours. Being powdered, and put into a sound cask, one-fourth of their weight of sulphuric acid is poured over them by degrees, stirring the mixture well at each addition. As soon as the muriatic gas is dissipated, a quantity of water equal to the acid is added, and the mixture stirred as before. When the heat is abated, a little more water is poured in, and this is repeated till eight or ten times as much water as there was acid is added. When the whole has settled, the clear liquor is drawn off into leaden vessels, and a quantity of water equal to this liquor is poured on the sediment. The two liquors being mixed, a solution of potassa is added to them, the alkali in which is equal to one-fourth of the weight of the sulphuric acid. Sulphate of potassa may be used, but twice as much of this as of the alkali is necessary. After a certain time, the liquor, by cooling, affords crystals of alum equal to three times the weight of the acid used. It is refined by dissolving it in the smallest possible quantity of boiling water. The residue may be washed with more water, to be employed in lixiviating a fresh portion of the ingredients.

Its sp. gravity is about 1.71. It reddens the vegetable blues. It is soluble in 16 parts of water at 60°, and in $\frac{3}{4}$ of its weight at 212°. It effloresces superficially on exposure to air, but the interior remains long unchanged. Its water of crystallization is sufficient at a gentle heat to fuse it. If the heat be increased it froths up, and loses fully 45 per cent. of its weight in water. The spongy residue is called *burnt* or calcined *alum*, and is used by surgeons as a mild escharotic. A violent heat separates a great portion of its acid.

Alum was thus analysed by Berzelius: 1*st*, 20 parts (grammes) of pure alum lost, by the heat of a spirit lamp, 9 parts, which gives 45 per cent. of water. The dry salt was dissolved in water, and its acid precipitated by muriate of barytes; the sulphate of which, obtained after ignition, weighed 20 parts; indicating in 100 parts 34.3 of dry sulphuric acid. 2*d*, Ten parts of alum were dissolved in water, and digested with an excess of ammonia. Alumina, well washed and burnt, equivalent to 10.67 per cent. was obtained. In another experiment, 10.86 per cent. resulted. 3*d*, Ten parts of alum dissolved in water, were digested with carbonate of strontites, till the earth was completely separated. The sulphate of potassa, after ignition, weighed 1.815, corresponding to 0.981 potassa, or in 100 parts to 9.81.

Alum, therefore, consists of

Sulphuric acid,	34.33
Alumina,	10.86
Potassa,	9.81
Water,	45.00
	100.00

or, Sulphate of alumina,	36.85
Sulphate of potassa,	18.15
Water,	45.00
	100.00

Thenard's analysis, Ann. de Chimie, vol. 59, or Nicholson's Journal, vol. 18, coincides perfectly with that of Berzelius in the product of sulphate of barytes. From 400 parts of alum, he obtained 490 of the ignited barytic salt; but the alumina was in greater proportion, equal to 12.54 per cent. and the sulphate of potassa less, or 15.7 in 100 parts.

Vauquelin, in his last analysis, found 48.58 water; and by Thenard's statement there are indicated 34.23 dry acid,

34.23	dry acid,
7.14	potassa,
12.54	alumina,
46.09	water,
100.00	

If we rectify Vauquelin's erroneous estimate of the sulphate of barytes, his analysis will also coincide with the above. Alum, therefore, differs from the simple sulphate of alumina previously described, which consisted of 3 prime equivalents of acid and 2 of earth, merely by its assumption of a prime of sulphate of potassa. It is probable that all the aluminous salts have a similar constitution. It is to be observed, moreover, that the number 34.36 resulting from the theoretic proportions, is, according to Gilbert's remarks on the Essay of Berzelius, the just representation of the dry acid in 100 of sulphate of barytes, by a corrected analysis, which makes the prime of barytes 9.57.

Should ammonia be suspected in alum, it may be detected, and its quantity estimated by mixing quicklime with the saline solution, and exposing the mixture to heat in a retort, connected with a Woolfe's apparatus. The water of ammonia being afterwards saturated with an acid, and evaporated to a dry salt, will indicate the quantity of pure ammonia in the alum. A variety of alum, containing both potassa and ammonia, may also be found. This will occur where urine has been used, as well as muriate of potassa, in its fabrication. If any of these bisulphates of alumina and potassa be acted on in a watery solution, by gelatinous alumina, a neutral triple salt is formed, which precipitates in a nearly insoluble state.

When alum in powder is mixed with flour or sugar, and calcined, it forms the *pyrophorus* of Homberg.

Mr. Winter first mentioned, that another variety of alum can be made with *soda*, instead of potassa. This salt, which crystallizes in octahedrons, has been also made with pure muriate of soda, and bisulphate of alumina, at the laboratory of Hurlett, by Mr. W. Wilson. It is extremely difficult to form, and effloresces like the sulphate of soda.

On the subject of soda-alum, Dr. Ure published a short paper in the Journal of Science for July, 1822. The form and taste of this salt are exactly the same as those of common alum; but it is less hard, being easily crushed between the fingers, to which it imparts an appearance of moisture. Its specific gravity is 1.6. 100 parts of water at 60° F. dissolve 110 of it; forming a solution, whose sp. gravity is 1.296. In this respect, potassa alum is very different. For 100 parts of water dissolve only from 8 to 9 parts, forming a saturated solution, the specific gravity of which is no more than 1.0465. Its constituents are by Dr. Ure's analysis,—

Sulphuric acid,	34.00	4 primes,		33.96
Alumina,	10.75	3	—	10.82
Soda,	6.48	1	—	6.79
Water,	49.00	25	—	48.43
	100.23			100.00

Or it consists of 3 primes sulphate of alumina + 1 sulphate of soda. To each of the former, 5 primes of water may be assigned, and to the latter 10, as in Glauber's salts.

The only injurious *contamination* of alum is sulphate of iron. It is detected by ferro-prussiate of potassa.

Oxymuriate of alumina, or the chloride, has been proposed by Mr. Wilson of Dublin, as preferable to solution of chlorine, for discharging the turkey-red die.

Alum is used in large quantities in many manufactories. When added to tallow, it renders it harder. Printer's cushions, and the blocks used in the calico manufactory, are rubbed with burnt alum to remove any greasiness, which might prevent the ink or colour from sticking. Wood sufficiently soaked in a solution of alum does not easily take fire; and the same is true of paper impregnated with it, which is fitter to keep gunpowder, as it also excludes moisture. Paper impregnated with alum is useful in whitening silver, and in silvering brass without heat. Alum mixed in milk helps the separation of its butter. If added in a very small quantity to turbid water, in a few minutes it renders it perfectly limpid, without any bad taste or quality; while the sulphuric acid imparts to it a very sensible acidity, and does not precipitate as soon, or so well, the opaque earthy mixtures that render it turbid. It is used in making pyrophorus, in tanning, and many other manufactories, particularly in the art of dieing, in which it is of the greatest and most important use, by cleansing and opening the pores on the surface of the substance to be died, rendering it fit for receiving the colouring particles, (by which the alum is generally decomposed,) and at the same time making the colour fixed. Crayons generally consist of the earth of alum, powdered, and tinged for the purpose.—*Ure's Chem. Dict.*

In medicine it is employed internally as a powerful astringent in cases of passive hæmorrhages from the womb, intestines, nose, and sometimes lungs. In bleedings of an active nature, i. e. attended with fever, and a plethoric state of the system, it is highly improper. Dr. Percival recommends it in the *colica pictonum* and other chronic disorders of the bowels, attended with obstinate constipation. (See Percival's Essays.) The dose advised in these cases is from 5 to 20 grains, to be repeated every four, eight, or twelve hours. When duly persisted in, this remedy proves gently laxative, and mitigates the pain.

Alum is also powerfully tonic, and is given with this view in the dose of 10 grains made into a bolus three times a day, in such cases as require powerful tonic and astringent remedies. Another mode of administering it is in the form of whey made by boiling a drachm of powdered alum in a pint of milk for a few minutes, and to be taken in the quantity of a tea-cup full three times a day. Dr. Cullen thinks it ought to be employed with other astringents in diarrhœas. In active hæmorrhagies, as was observed, it is not useful, though a powerful medicine in those which are passive. It should be given in small doses, and gradually increased. It has been tried in the diabetes without success; though, joined with nutmeg, it has been more successful in intermittents, given in a large dose, an hour or a little longer, before the approach of the paroxysm. In gargles, in relaxation of the uvula, and other swellings of the mucous membrane of the fauces, divested of acute inflammation, it has been used with advantage.

Externally, alum is much employed by surgeons as a lotion for the eyes, and is said to be preferable to sulphate of zinc or acetate of lead in the ophthalmia membranarum. From two to five grains dissolved in an ounce of rose water, forms a proper collyrium. It is also applied as a styptic to bleeding vessels, and to ulcers, where there is too copious a secretion of pus. It has proved successful in inflammation of the eyes, in the form of cataplasm, which is made by stirring or shaking a lump of alum in the whites of two eggs, till they form a coagulum, which is applied to the eye between two pieces of thin linen rag. Alum is also employed as an injection in cases of gleet or fluor albus.

When deprived of its humidity, by placing it in an earthen pan over a gentle fire, it is termed burnt alum, *alumen exsiccatum*, and is sometimes employed by surgeons to destroy fungous flesh, and is a principal ingredient in most styptic powders.

Alum is also applied to many purposes of life; in this country, bakers mix a quantity with the bread, to render it white; this mixture makes the bread better adapted for weak and relaxed bowels; but in opposite states of the alimentary canal, this practice is highly pernicious.

The officinal preparations of alum are:

1. Alumen exsiccatum.
2. Solutio sulphatis cupri ammoniati.
3. Liquor aluminis compositus.

4. Pulvis sulphatis aluminis compositus.

ALUMEN CATINUM. A name of potassa.

ALUMEN COMMUNE. See *Alumen.*

ALUMEN CRYSTALLINUM. See *Alumen.*

ALUMEN EXSICCATUM. Dried alum. Expose alum in an earthen vessel to the fire so that it may dissolve and boil, and let the heat be continued and increased until the boiling ceases. See *Alumen.*

ALUMEN FACTITIUM. See *Alumen.*

ALUMEN ROMANUM. See *Alumen.*

ALUMEN RUBRUM. See *Alumen.*

ALUMEN RUPEUM. See *Alumen.*

ALUMEN RUTILUM. See *Alumen.*

ALUMEN USTUM. See *Alumen.*

ALU'MINA. Alumine. *Terra Alumina.* Earth of alum. Pure clay. One of the primitive earths, which, as constituting the plastic principle of all clays, loams, and boles, was called argil or the argillaceous earth, but now, as being obtained in greatest purity from alum, is styled alumina. It was deemed elementary matter till Sir H. Davy's celebrated electro-chemical researches led to the belief of its being, like barytes and lime, a metallic oxyde.

The purest native alumina is found in the oriental gems, the sapphire and ruby. They consist of nothing but this earth, and a small portion of colouring matter. The native porcelain clays or kaolins, however white and soft, can never be regarded as pure alumina. They usually contain fully half their weight of silica, and frequently other earths. To obtain pure alumina we dissolve alum in 20 times its weight of water, and add to it a little of the solution of carbonate of soda, to throw down any iron which may be present. We then drop the supernatant liquid into a quantity of the water of ammonia, taking care not to add so much of the aluminous solution as will saturate the ammonia. The volatile alkali unites with the sulphuric acid of the alum, and the earthy basis of the latter is separated in a white spongy precipitate. This must be thrown on a filter, washed, or edulcorated, as the old chemists expressed it, by repeated affusions of water, and then dried. Or if an alum, made with ammonia instead of potassa, as is the case with some French alums, can be got, simple ignition dissipates its acid and alkaline constituents, leaving pure alumina.

Alumina prepared by the first process is white, pulverulent, soft to the touch, adheres to the tongue, forms a smooth paste without grittiness in the mouth, insipid, inodorous, produces no change in vegetable colours, insoluble in water, but mixes with it readily in every proportion, and retains a small quantity with considerable force; is infusible in the strongest heat of a furnace, experiencing merely a condensation of volume and consequent hardness, but is in small quantities melted by the oxyhydrogen blowpipe. Its specific gravity is 2.000 in the state of powder, but by ignition it is augmented.

Every analogy leads to the belief that alumina contains a peculiar metal, which may be called *aluminum.* The first evidences obtained of this position are presented in Sir H. Davy's researches. Iron negatively electrified by a very high power being fused in contact with pure alumina, formed a globule whiter than pure iron which effervesced slowly in water, becoming covered with a white powder. The solution of this in muriatic acid, decomposed by an alkali, afforded alumina and oxyde of iron. By passing potassium in vapour through alumina heated to whiteness, the greatest part of the potassium became converted into potassa, which formed a coherent mass with that part of the alumina not decompounded; and in this mass there were numerous gray particles, having the metallic lustre, and which became white when heated in the air, and which slowly effervesced in water. In a similar experiment made by the same illustrious chemist, a strong red heat only being applied to the alumina, a mass was obtained, which took fire spontaneously by exposure to air, and which effervesced violently in water. This mass was probably an alloy of aluminum and potassium. The conversion of potassium into its deutoxyde, dry potassa, by alumina, proves the presence of oxygen in the latter. When regarded as an oxyde, Sir H. Davy estimates its oxygen and basis to be to one another as 15 to 33; or as 10 to 22. The prime equivalent of alumina would thus appear to be $1.0 + 2.2 = 3.2$. But Berzelius's analysis of sulphate of alumina seems to indicate 2.136 as the quantity of the earth which combines with 5 of the acid. Hence aluminum will come to be represented by $2.136 - 1 = 1.136$.

Alumina which has lost its plasticity by ignition, recovers it by being dissolved in an acid or alkaline menstruum, and then precipitated. In this state it is called a hydrate, for when dried in a steam heat it retains much water; and therefore resembles in composition wavellite, a beautiful mineral, consisting almost entirely of alumina, with about 28 per cent. of water.

Alumina is widely diffused in nature. It is a constituent of every soil, and of almost every rock. It is the basis of porcelain, pottery, bricks, and crucibles. Its affinity for vegetable colouring matter, is made use of in the preparation of lakes, and in the arts of dieing and calico printing. Native combinations of alumina, constitute the fullers' earth, ochres, boles, pipe-clays, &c.

The salts of alumina have the following general characters:

1. Most of them are very soluble in water, and their solutions have a sweetish acerb taste.

2. Ammonia throws down their earthy base, even though they have been previously acidulated with muriatic acid.

3. At a strong red heat they give out a portion of their acid.

4. Phosphate of ammonia gives a white precipitate.

5. Hydriodate of potassa produces a flocculent precipitate of a white colour, passing into a permanent yellow.

6. They are not affected by oxalate of ammonia, tartaric acid, ferroprussiate of potassa, or tincture of galls: by the first two tests they are distinguishable from yttria; and by the last two, from that earth and glucina.

7. If bisulphate of potassa be added to a solution of an aluminous salt moderately concentrated, octahedral crystals of alum will form.

ALUMINITE. A mineral of a snow white colour, dull, opaque, and having a fine earthy fracture. It consists of sulphuric acid, alumina, water, silica, lime, and oxyde of iron.

ALUMINOUS. Pertaining to alum.

Aluminous waters. Waters impregnated with particles of alum.

ALUMINUM. See *Alumina.*

ALUSAR. Manna.

ALUSIA. (From *αλυσις* a wandering.) *Alysis;* Illusion; Hallucination. A term used by Good to a species of his genus *Empathemata.* See *Nosology.*

ALVEAR'IUM. (From *alveare,* a bee-hive.) That part of the meatus auditorius externus is so called, which contains the wax of the ear.

ALVE'OLUS. (A diminutive of *alveus*, a cavity.) The socket of a tooth.

A'LVEUS. (*Alveus, i.* m., a cavity.) A cavity.

ALVEUS AMPULLESCENS. That part of the duct conveying the chyle to the subclavian vein, which swells out.

ALVEUS COMMUNIS. The common duct, or communication of the ampullæ of the membranaceous semicircular canals in the internal ear, is so termed by Scarpa.

ALVIDU'CA. (From *alvus*, the belly, and *duco*, to draw.) Purging medicines.

ALVIFLUXUS. (From *alvus*, and *fluo*, to flow.) A diarrhœa, or purging.

ALVUS. (*Alvus, i.* f. and sometimes m. *ab alluendo, quâ sordes alluuntur.*) The belly, stomach, and entrails.

A'LYCE. (From αλυω, to be anxious.) That anxiety which attends low fevers.

ALY'PIA. (From α, neg. and λυπη, pain.) Without pain; applied to a purgation of the humours without pain.

ALY'PIAS. *Alypum.* A species of turbith, the *globularia alypum*; so called because it purges without pain.

ALYSIS. See *Alusia.*

ALY'SMUS. (From αλυω, to be restless.) Restlessness.

ALY'SSUM. (From α, neg. and λυσσα, the bite of a mad dog; so called because it was foolishly thought to be a specific in the cure of the bite of a mad dog.) Mad-wort. See *Marrubium alyssum.*

ALYSSUM GALENI. See *Marrubium verticillatum.*

ALYSSUM PLINII. See *Galium album.*

ALYSSUM VERTICILLATUM. The *Marrubium verticillatum.*

ALZE'MAFOR. Cinnabar.

A'LZUM. *Aldum; Aldrum.* The name of the tree which produces gum bdellium, according to some ancient authors.

A'MA. (Αμα, together.) A word used in composition.

AMADINE. A substance, the properties of which are intermediate between those of starch and gum. See *Starch.*

AMADOU. A variety of the *boletus igniarius*, found on old ash and other trees. It is boiled in water to extract its soluble parts, then dried and beat with a mallet to loosen its texture. It has now the appearance of very spongy doeskin leather. It is lastly impregnated with a solution of nitre, and dried, when it is called spunk, or German tinder; a substance much used on the continent for lighting fires, either from the collision of flint and steel, or from the sudden condensation of air in the atmospheric pyrophorus.

AMA'LGAM. (*Amalgama;* from αμα, and γαμειν, to marry.) A substance produced by mixing mercury with a metal, the two being thereby incorporated. See *Alloy.*

AMAME'LIS. (From αμα, and μηλεα, an apple.) The bastard medlar of Hippocrates.

AMANI'TÆ. (From α, priv. and μανια, madness; so called, because they are eatable and not poisonous, like some others,) A tribe of fungous productions, called mushrooms, truffles, and morells, and by the French, champignons.

AMARA DULCIS. See *Solanum dulcamara.*

AMA'RACUS. (From α, neg. and μαραινω, to decay: because it keeps its virtues a long time.) Marjoram.

Amaranth, esculent. See *Amaranthus oleraceus.*

AMARA'NTHUS. (*Amaranthus, i.* m.; from α, neg. and μαραίνω, to decay: because the flower, when cut, does not soon decay.) The name of a genus of plants in the Linnæan system. Class, *Monœcia;* Order, *Pentandria.*

AMARANTHUS OLERACEUS. *Esculent amaranth.* The leaves of this, and several other species, are eaten in India the same as cabbage is here.

AMA'RUS. Bitter. See *Bitter.* The principal bitters used medicinally are,

1. The *pure bitters;* gentiana lutea, humulus lupulus, and quassia amara.

2. *Styptic bitters;* cinchona officinalis, croton cascarilla, quassia simarouba.

3. *Aromatic bitters;* artemisia absinthium, anthemis nobilis, hyssopus, &c.

AMATORIA FEBRIS. (From *amo*, to love.) See *Chlorosis.*

AMATORIA VENEFICIA. (From *amo*, to love, and *veneficium*, witchcraft.) Philters. Love powders.

AMATO'RIUS. A term given to a muscle of the eye, by which that organ is moved in ogling. See *Rectus inferior oculi.*

AMATZQUI'TI. An Indian term. See *Arbutus unedo.*

AMAURO'SIS. (*Amauroses, is.* f. Αμαυρωσις; from αμαύροω, to darken or obscure.) *Gutta serena; Amblyopia.* A disease of the eye, attended with a diminution or total loss of sight, without any visible injury to the organ, and arising from a paralytic affection of the retina and optic nerve. A genus of disease in the class *locales*, and order *dysæsthesiæ* of Cullen. It arises generally from compression of the optic nerves; *amaurosis compressionis;* from debility, *amaurosis atonica;* from spasm, *amaurosis spasmodica;* or from poisons, *amaurosis venenata.*

The symptoms of amaurosis are noted for being very irregular. In many cases, the pupil is very much dilated, immoveable and of its natural black colour. Sometimes, however, in the most complete and incurable cases, the pupil is of its natural size, and the iris capable of free motion. In some cases, the pupil has a dull, glassy, or horny appearance. Sometimes its colour is greenish, occasionally whitish and opaque, so as to be liable to be mistaken for an incipient cataract. Richter mentions a degree of strabismus, as the only symptom, except the loss of sight, as invariably attendant on amaurosis.

The blindness produced by amaurosis, is generally preceded by an imaginary appearance of numerous insects, or substances like cobwebs, interposing themselves between objects and the eye. The origin of a cataract, on the other hand, is usually attended with a simple cloudiness of vision.

Violent contusions of the head, apoplectic fits, flashes of lightning, frequent exposure to the rays of the sun, severe exercise, strong passions, drunkenness, and other causes of paralytic affections, are enumerated as producing this complaint. Sometimes tumours within the cranium, bony projections, &c. have been found compressing the optic nerves; but in many instances no morbid appearance could be traced, to account for the blindness.

The disorder is generally difficult to be removed: but is sometimes much benefited by general and local stimulants, persevered in for a considerable time. If there are marks of congestion in the head, local bleeding, active purging and other evacuations would be proper in the first instance. Blisters and issues behind the ear or neck should also be tried. Richter speaks of much success from the use of medicines acting steadily on the bowels, after premising an emetic. Mr. Ware observes, that in some cases the pupil is contracted, indicating probably, internal inflammation; and then the internal use of mercury, especially the oxymuriate, will be most beneficial. Electricity has been sometimes serviceable, taking the aura or sparks, or even gentle shocks; but galvanism is certainly preferable. Errhines are often useful, as the compound powder of asarabacca; Mr. Ware particularly recommends the hydrargyrus vitriolatus of the former London Pharmacopœia. Stimulants have been sometimes usefully applied to the eye itself, as the vapour of oil of turpentine, an infusion of capsicum, &c. Where the intention of a blister is to stimulate, it is best applied to the temple on the affected side.

A'MBE. (Αμβη, the edge of a rock; from *αμβαινω*, to ascend.) An old chirurgical machine for reducing dislocations of the shoulder, and so called, because its extremity projects like the prominence of a rock. Its invention is imputed to Hippocrates. The ambe is the most ancient mechanical contrivance for the above purpose, but is not used at present.

A'MBELA. (Arabian.) The cornered hazlenut, the bark of which is purgative.

AMBER. *Succinum.* A beautiful bituminous substance, which takes a good polish, and, after a slight rubbing, becomes so electric, as to attract straws and small bodies; it was called *ηλεκτρον*, *electrum*, by the ancients, and hence the word electricity. "Amber is a hard, brittle, tasteless substance, sometimes perfectly transparent, but mostly semitransparent or opaque, and of a glossy surface: it is found of all colours, but chiefly yellow or orange, and often contains leaves or insects; its specific gravity is from 1.065 to 1.100; its fracture is even, smooth, and glossy; it is capable of a fine polish, and becomes electric by friction; when rubbed or heated, it gives a peculiar agreeable smell, particularly when it melts, that is at 550° of Fahrenheit, but it then loses its transparency; projected on burning coals, it burns with a whitish flame, and a whitish-yellow smoke, but gives very little soot, and leaves brownish ashes; it is insoluble in water and alcohol, though the latter, when highly rectified, extracts a reddish colour from it; but it is soluble in the sulphuric acid, which then acquires a reddish-purple colour, and is precipitable from it by water. No other acid dissolves it, nor is it soluble in essential or expressed oils, without some decomposition and long digestion; but pure alkali dissolves it. By distillation it affords a small quantity of water, with a little acetous acid, an oil, and a peculiar acid. The oil rises at first colourless; but, as the heat increases, becomes brown, thick, and empyreumatic. The oil may be rectified by successive distillations, or it may be obtained very light and limpid at once, if it be put into a glass alembic with water, as the elder Rouelle directs, and distilled at a heat not greater than 212° Fahr. It requires to be kept in stone bottles, however, to retain this state; for in glass vessels it becomes brown by the action of light.

Amber is met with plentifully in regular mines in some parts of Prussia. The upper surface is composed of sand, under which is a stratum of loam, and under this a bed of wood, partly entire, but chiefly mouldered or changed into a bituminous substance. Under the wood is a stratum of sulphuric or rather aluminous mineral, in which the amber is found. Strong sulphureous exhalations are often perceived in the pits.

Detached pieces are also found occasionally on the sea-coast in various countries. It has been found in gravel beds near London. In the Royal Cabinet at Berlin there is a mass of 18lbs. weight, supposed to be the largest ever found. Jussieu asserts, that the delicate insects in amber, which prove the tranquillity of its formation, are not European. Hauy has pointed out the following distinctions between mellite and copal, the bodies which most closely resemble amber. Mellite is infusible by heat. A bit of copal heated at the end of a knife takes fire, melting into drops, which flatten as they fall; whereas amber burns with spitting and frothing; and when its liquefied particles drop, they rebound from the plane which receives them. The origin of amber is at present involved in perfect obscurity, though the rapid progress of vegetable chemistry promises soon to throw light on it. Various frauds are practised with this substance. Neumann states as the common practices of workmen, the two following: The one consists in surrounding the amber with sand in an iron pot, and cementing it with a gradual fire for forty hours, some small pieces placed near the sides of the vessel being occasionally taken out for judging of the effect of the operation: the second method, which he says is that most generally practised, is by digesting and boiling the amber about twenty hours with rapeseed oil, by which it is rendered both clear and hard.

Werner has divided it into two sub-species, the white and the yellow; but there is little advantage in the distinction. Its ultimate constituents are the same with those of vegetable bodies in general; viz. carbon, hydrogen, and oxygen.

In the second volume of the Edinburgh Philosophical Journal, Dr. Brewster has given an account of some optical properties of amber, from which he considers it established beyond a doubt that amber is an *indurated vegetable juice;* and that the traces of a regular structure, indicated by its action upon polarized light, are not the effect of the ordinary laws of crystallization by which *mellite* has been formed, but are produced by the same causes which influence the mechanical condition of gum-arabic, and other gums, which are known to be formed by the successive deposition and induration of vegetable fluids."—*Ure's Chem. Dict.* See *Oleum Succini*, and *Succinic Acid.*

AMBER SEED. See *Hibiscus abelmoschus.*

AMBERGRIS. (*Ambragrisea, æ.* f.) A concrete, found in very irregular masses, floating on the sea near the Molucca islands, Madagascar, Sumatra, on the coast of Coromandel, Brazil, America, China, and Japan. It has also been taken out of the intestines of the *Physeter macrocephalus*, the spermaceti whale. As it has not been found in any whales but such as are dead or sick, its production is generally supposed to be owing to disease, though some have a little too peremptorily affirmed it to be the cause of the morbid affection. As no large piece has ever been found without a greater or less quantity of the beaks of the *Sepia octopodia*, the common food of the spermaceti whale, interspersed throughout its substance, there can be little doubt of its originating in the intestines of the whale; for if it were occasionally swallowed by it only, and then caused disease, it would be frequently found without these, when it is met with floating or thrown upon the shore.

Ambergris is found of various sizes, generally in small fragments, but sometimes so large as to weigh near two hundred pounds. When taken from the whale it is not so hard as it becomes afterward on exposure to the air. Its specific gravity ranges from 780 to 926. If good, it adheres like wax to the edge of a knife with which it is scraped, retains the impression of the teeth or nails, and emits a fat odoriferous liquid on being penetrated with a hot needle. It is generally brittle; but, on rubbing it with the nail, it becomes smooth like hard soap. Its colour is either white, black, ash-coloured, yellow, or blackish; or it is variegated, namely, gray with black specks, or gray with yellow specks. Its smell is peculiar, and not easy to be counterfeited. At 144° it melts, and at 212° is volatilised in the form of a white vapour. But, on a red-hot coal, it burns, and is entirely dissipated. Water has no action on it; acids, except nitric, act feebly on it; alkalies combine with it, and form a soap; æther and the volatile oils dissolve it; so do the fixed oils, and also ammonia, when assisted by heat; alcohol dissolves a portion of it, and is of great use in analysing it, by separating its constituent parts. According to Bouillon la Grange, who has given the latest analysis of it, 3820 parts of ambergris consist of adipocire 2016 parts, a resinous substance 1167, benzoic acid 425, and coal 212. But Bucholtz could find no benzoic acid in it. Dr. Ure examined two different specimens with considerable attention. The one yielded benzoic acid, the other, equally genuine to all appearance, afforded none.

An alcoholic solution of ambergris, added in minute quantity to lavender water, tooth powder, hair powder, wash balls, &c. communicates its peculiar fragrance. Its retail price being in London so high as a guinea per oz. leads to many adulterations. These consist of various mixtures of benzoin, labdanum, meal, &c. scented with musk. The greasy appearance and smell which heated ambergris exhibits, afford good *criteria*, joined to its solubility in hot æther and alcohol.

It has occasionally been employed in medicine, but its use is mostly confined to the perfumer. Dr. Swediaur took thirty grains of it without perceiving any sensible effect. A sailor, who took half an ounce of it, found it a good purgative.—*Ure's Chem. Dict.*

The medical qualities of ambergris are stomachic, cordial, and antispasmodic. It is very seldom used in this country.

AMBLO′SIS. (Αμβλωσις; from αμβλοω, to cause abortion.) A miscarriage.

AMBLO′TICA. (Αμβλωτικα; from αμβλοω, to cause abortion.) Medicines which were supposed to occasion abortion.

AMBLYGONITE. A greenish-coloured mineral that occurs in granite, along with green topaz and tourmaline, near Pinig in Saxony. It seems to be a species of spodumine.

AMBLYO′PIA. (*Amblyopia, æ.* f.; from αμβλος, dull, and ωψ, the eye.) *Amblyosmus; Amblytes.* Hippocrates means by this word, dimness of sight to which old people are subject. Paulus Actuarius, and the best modern writers, seem to think that amblyopia means the same thing as the incomplete amaurosis. See *Amaurosis.*

AMBLYO′SMUS. See *Amblyopia.*

AMBLYTES. See *Amblyopia.*

A′MBO. An Indian name of the mango.

A′MBON. (From αμβαινω, to ascend.) Celsus uses this term to signify the margin or tip of the sockets in which the heads of the large bones are lodged.

A′MBONE. The same as ambe.

A′MBRA. Amber. Also an aromatic gum.

AMBRA CINERACEA. Ambergris and gray amber.

AMBRA GRISEA. Ambergris.

A′MBRAM. Amber.

AMBRE′TTE. See *Hibiscus abelmoschus.*

AMBULATI′VA. (From *ambulo,* to walk.) A species of herpes; so called because it walks or creeps, as it were, about the body.

A′MBULO. (From αμβαλλω, to cast forth.) *Flatus furiosus.* A periodical flatulent disease caused, according to Michaelis, by vapours shooting through various parts of the body.

AMBU′STIO. (*Ambustio, onis.* f.; from *amburo,* to burn.) See *Burn.*

AMBUSTUM. A burn or scald.

AME′LLA. The same as achmella.

AMENORRHŒA. (*Amenorrhœa, æ.* f.; from α, priv. μην, a month, and ῥεω, to flow.) A partial or total obstruction of the menses in women from other causes than pregnancy and old age. The menses should be regular as to quantity and quality; and that this discharge should observe the monthly period, is essential to health. When it is obstructed, nature makes her efforts to obtain for it some other outlet. When these efforts of nature fail, the consequence may be, pyrexia, pulmonic diseases, spasmodic affections, hysteria, epilepsia, mania, apoplexia, chlorosis, according to the general habit and disposition of the patient. Dr. Cullen places this genus in the class *locales,* and order *epischeses.* His species are, 1. *Emansio mensium;* that is, when the menses do not appear so early as is usually expected. See *Chlorosis.* 2. *Suppressio mensium,* when, after the menses appearing and continuing as usual for some time, they cease without pregnancy occurring. 3. *Amenorrhœa difficilis, vel Menorrhagia difficilis,* when this flux is too small in quantity, and attended with great pain, &c.

The causes of a suppression of the menses appear mostly to operate by inducing a constriction of the extreme vessels; such as cold, fear, and other depressing passions, an indolent life, the abuse of acids, &c. It is sometimes symptomatic of other diseases, in which considerable debility occurs, as phthisis pulmonalis. When the discharge has been some time interrupted, particularly in persons previously healthy, hæmorrhages will often happen from other outlets, the nose, stomach, lungs, &c. even in some instances a periodical discharge of blood from an ulcer has occurred. The patient generally becomes obstinately costive, often dyspeptic; colicy pains, and various hysterical symptoms likewise are apt to attend. The means of chief efficacy in restoring the uterine function are those calculated to relax spasm, assisted sometimes by such as increase arterial action, particularly in protracted cases. The former will be employed with most probability of success, when symptoms of a menstrual effort appear. They are, especially the hipbath, fomentations to the hypogastrium, sitting over a vessel of hot water, so that the vapour may be applied to the pudenda; with antispasmodic medicines, as the compound galbanum pill, castor, &c. but especially opium. If the patient be plethoric, venæsection should be premised. In cases of long standing, the object will be to bring about a determination of blood to the uterus. This may be accomplished by emmenagogues, of which savine and cantharis are most to be relied upon; though the latter would be improper, if hœmaturia had occurred. Certain cathartics are also very useful, particularly aloes, which appear to operate especially on the rectum, and thus sympathetically influence the uterus. Electric shocks passed through the hypogastric region, may likewise contribute to the cure.

In cases of scanty and painful menstruation, the means pointed out above as calculated to take off constriction of the uterine vessels, should be resorted to; especially the hip-bath, and the free use of opium.

AMENTACEÆ PLANTÆ. Amentaceous plants. A division of plants in natural arrangements of botanists.

AMENTA′CEUS. Having an amentum or catkin, as the willow, birch, beech, poplar, &c.

AME′NTIA. (*Amentia*, *æ*. f.; from *a*, priv. and *mens*, the mind.) Imbecility of intellect, by which the relations of things are either not perceived, or not recollected. A disease in the class *neuroses*, and order *vesaniæ* of Cullen. When it originates at birth, it is called *amentia congenita*, natural stupidity; when from the infirmities of age, *amentia senilis*, dotage or childishness; and when from some accidental cause, *amentia acquisita*.

AME′NTUM. (Derived from its fancied resemblance to a cat's-tail, and by Festus, from the Greek ἁμμα, a bond or thong.) *Julus*; *Nucamentum*; *Catulus*. Catkin. A species of inflorescence, considered by some as a species of calyx. It is a simple peduncle covered with numerous chaffy scales, under which are the flowers or parts of fructification. The distinctions of catkins are into,

1. *Cylindrical*: as in *Corylus avellana*; *Beta alba*; *Alnus*.

2. *Globose*: as in *Fagus sylvatica*; *Platanus orientalis*; *Urtica pilulifera*.

3. *Ovate*: as in the Female *Pinus sylvestris*.

4. *Filiform*: seen in *Fagus pumila* and *Castanea pumila*.

5. *Attenuate*, slender towards the end: as in *Fagus castanea*.

6. *Thick*: in *Juglans regia*.

7. *Imbrecate*, scaly: as in *Juniperus communis* and *Salix fusca*.

8. *Paleaceous*, chaffy: as in *Pinus sylvestris*.

9. *Naked*: the scales being so small or wanting, that the parts of fructification appear naked, as in *Excoccaria*.

American balsam. See *Myroxylon Peruiferum*.

AMERICA′NUM TUBEROSUM. The potatoe. See *Solanum tuberosum*.

AMETHY′STA PHARMACA. (From *α*, neg. and *μεθυ*, wine.) Medicines which were said either to prevent or remove the effects of wine.—*Galen*.

AMETHY′STUS. (From *α*, neg. and *μεθυσκω*, to be inebriated: so called, because in former times, according to Plutarch, it was thought to prevent drunkenness.—*Ruland. in Lex. Chem.*) The amethyst. "A gem of a violet colour, and great brilliancy, said to be as hard as the ruby or sapphire, from which it only differs in colour. This is called the oriental amethyst, and is very rare. When it inclines to the purple or rosy colour, it is more esteemed than when it is nearer to the blue. These amethysts have the same figure, hardness, specific gravity, and other qualities, as the best sapphires or rubies, and come from the same places, particularly from Persia, Arabia, Armenia, and the West Indies. The occidental amethysts are merely coloured crystals or quartz."

AMIANTHUS. See *Asbestos*.

AMI′CULUM. A little short cloak. It is the same as the amnios, but anciently meant a covering for the pubes of boys, when they exercised in the gymnasium.—*Rhodius*.

AMIDINE. A substance produced according to Saussure, when we abandon the paste of starch to itself, at the ordinary temperature, with or without the contact of air.

A′MIDUM. See *Amylum*.

AMINÆ′UM. A wine produced in Aminæa, formerly a province of Italy; called also Salernum. Also a strong wine vinegar. Galen mentions *Aminæum Neapolitanum*, and *Aminæum Siculum*.

A′MMI. (*Ammium*, *i*. n. Αμμι; from *αμμος*, sand, from its likeness to little gravel-stones.) 1. The name of a genus of plants in the Linnæan system.

2. The pharmacopœial name of the herb bishop's weed, of which there are two sorts. See *Sison ammi* and *ammi majus*.

AMMI MAJUS. The systematic name for the *ammi vulgare* of the shops. The seeds of this plant, *Ammi—foliis inferioribus pinnatis, lanceolatis serratis; superioribus, multifidis, linearibus*, of Linnæus; are less powerful than those of the *Sison ammi*, but were exhibited with the same views.

AMMI VE′RUM. See *Sison Ammi*.

AMMI VULGARE. See *Ammi majus*.

AMMION. *Ammium*. Cinnabar.

AMMOCHO′SIA. (From *αμμος*, sand, and *χεω*, to pour.) A remedy for drying the body by sprinkling it with hot sand.—*Oribasius*.

AMMO′NIA. (*Ammonia*, *æ*. f.; so called because it is obtained from sal ammoniac, which received its name from being dug out of the earth near the temple of Jupiter Ammon.) Ammonia gas. The substance so called is an aëriform or alkaline air. "There is a saline body, formerly brought from Egypt, where it was separated from soot by sublimation, but which is now made abundantly in Europe, called sal ammoniac. From this salt pure ammonia can be readily obtained by the following process: Mix unslacked quicklime with its own weight of sal ammoniac, each in fine powder, and introduce them into a glass retort. Join to the beak of the retort, by a collar of caoutchouc, (a neck of an India rubber bottle answers well,) a glass tube about 18 inches long, containing pieces of ignited muriate of lime. This tube should lie in a horizontal position, and its free end, previously bent obliquely by the blowpipe, should dip into dry mercury in a pneumatic trough. A slip of porous paper, as an additional precaution, may be tied round the tube, and kept moist with æther. If a gentle heat from a charcoal chauffer or lamp be now applied to the bottom of the retort, a gaseous body will bubble up through the mercury. Fill a little glass tube, sealed at one end, with the gas, and transfer it, closely stopped at the other end, into a basin containing water. If the water rise instantly and fill the whole tube, the gas is pure, and may be received for examination.

Ammonia is a transparent, colourless, and consequently invisible gas, possessed of elasticity, and the other mechanical properties of the atmospherical air. Its specific gravity is an important datum in chemical researches, and has been rather differently stated. Now as no aëriform body is more easily obtained in a pure state than ammonia, this diversity, among accurate experimentalists, shows the nicety of this statical operation. Biot and Arago make it = 0.59669 by experiment, and by calculation from its elementary gases, they make it = 0.59438. Kirwan says that 100 cubic inches weigh 18.16 gr. at 30 inches of bar. and 61° F., which compared to air reckoned 30.519, gives 0.59540. Sir H. Davy determines its density to be = 0.590, with which estimate the theoretic calculations of Dr. Prout, in the sixth volume of the Annals of Philosophy, agree.

This gas has an exceedingly pungent smell, well known by the old name of spirits of hartshorn. An animal plunged into it speedily dies. It extinguishes combustion, but being itself to a certain degree combustible, the flame of a taper immersed in it is enlarged before going out. It has a very acrid taste. Water condenses it very rapidly.

Water is capable of dissolving easily about one-third of its weight of ammoniacal gas, or 460 times its bulk. Hence, when placed in contact with a tube filled with this gas, water rushes into it with explosive velocity.

Ammoniacal gas, perfectly dry, when mixed with oxygen, explodes with the electric spark, and is converted into water and nitrogen, as has been shown in an ingenious paper by Dr. Henry. But the simplest, and perhaps most accurate mode of resolving ammonia into its elementary constituents, is that first practised by Berthollet, the celebrated discoverer of its composition. This consists in making the pure gas traverse very slowly an ignited porcelain tube of a small diameter.

The alkaline nature of ammonia is demonstrated, not only by its neutralising acidity, and changing the vegetable reds to purple or green, but also by its being attracted to the negative pole of a voltaic arrangement. When a pretty strong electric power is applied to ammonia in its liquid or solid combinations, simple decomposition is effected; but in contact with mercury, very mysterious phenomena occur. If a globule of mercury be surrounded with a little water of ammonia, or placed in a little cavity in a piece of sal ammoniac, and then subjected to the voltaic power by two wires, the negative touching the mercury, and the positive the ammoniacal compound, the globule is instantly covered with a circulating film, a white smoke rises from it, and its volume enlarges, whilst it shoots out ramifications of a semi-solid consistence over the salt. The amalgam has the consistence of soft butter, and may be cut with a knife. Whenever the electrization is suspended, the crab-like fibres retract towards the central mass, which soon, by the constant formation of white saline films, resumes its pristine globular shape and size. The enlargement of volume seems to amount occasionally to ten times that of the mercury, when a small globule is employed. Sir H. Davy, Berzelius, and Gay Lussac and Thenard, have studied this singular phenomenon with great care. They produced the very same substance by putting an amalgam of mercury and potassium into the moistened cupel of sal ammoniac. It becomes five or six times larger, assumes the consistence of butter, whilst it retains its metallic lustre.

What takes place in these experiments? In the second case, the substance of metallic aspect which we obtain is an ammoniacal hydruret of mercury and potassium. There is formed, besides, muriate of potassa. Consequently a portion of the potassium of the amalgam decomposes the water, becomes potassa, which itself decomposes the muriate of ammonia. Thence result hydrogen and ammonia, which, in the nascent state, unite to the undecomposed amalgam. In the first experiment, the substance which, as in the second, presents the metallic aspect, is only an ammoniacal hydruret of mercury; its formation is accompanied by the perceptible evolution of a certain quantity of chlorine at the positive pole. It is obvious, therefore, that the salt is decomposed by the electricity. The hydrogen of the muriatic acid, and the ammonia, both combine with the mercury.

Ammonia is not affected by a cherry-red heat. According to Guyton de Morveau, it becomes a liquid at about 40°—0°, or at 0° the freezing point of mercury; but it is uncertain whether the appearances he observed may not have been owing to hygrometric water, as happens with chlorine gas. The ammoniacal liquid loses its pungent smell as its temperature sinks, till at —50° it gelatinizes, if suddenly cooled; but if slowly cooled it crystallises.

Oxygen, by means of electricity, or a mere red heat, resolves ammonia into water and nitrogen. When there is a considerable excess of oxygen, it acidifies a portion of the nitrogen into nitrous acid, whence many fallacies in analysis have arisen. Chlorine and ammonia exercise so powerful an action on each other, that when mixed suddenly, a sheet of white flame pervades them. The simplest way of making this fine experiment, is to invert a matrass, with a wide mouth and conical neck, over another with a taper neck, containing a mixture of sal ammoniac and lime, heated by a lamp. As soon as the upper vessel seems to be full of ammonia, by the overflow of the pungent gas, it is to be cautiously lifted up, and inserted, in a perpendicular direction, into a wide-mouthed glass decanter or flask, filled with chlorine. On seizing the two vessels thus joined with the two hands covered with gloves, and suddenly inverting them, like a sand-glass, the heavy chlorine and light ammonia, rushing in opposite directions, unite, with the evolution of flame. As one volume of ammonia contains, in a condensed state, one and a half of hydrogen, which requires for its saturation just one and a half of chlorine, this quantity should resolve the mixture into muriatic acid and nitrogen, and thereby give a ready analysis of the alkaline gas. If the proportion of chlorine be less, sal ammoniac and nitrogen are the results. The same thing happens on mixing the aqueous solutions of ammonia and chlorine. But if large bubbles of chlorine be let up in ammoniacal water of moderate strength, luminous streaks are seen in the dark to pervade the liquid, and the same reciprocal change of the ingredients is effected.

Gay Lussac and Thenard state, that when 3 parts of ammoniacal gas and 1 of chlorine are mixed together, they condense into sal ammoniac, and azote, equal to 1-10 the whole volume, is given out.

Iodine has an analogous action on ammonia; seizing a portion of its hydrogen to form hydriodic acid, whence hydriodate of ammonia results; while another portion of iodine unites with the liberated nitrogen to form the explosive pulverulent iodine.

Cyanogen and ammoniacal gas begin to act upon each other whenever they come into contact, but some hours are requisite to render the effect complete. They unite in the proportion nearly of 1 to 1½, forming a compound which gives a dark orange-brown colour to water, but dissolves in only a very small quantity of water. The solution does not produce prussian blue with the salts of iron.

By transmitting ammoniacal gas through charcoal ignited in a tube, prussic or hydrocyanic acid is formed.

The action of the alkaline metals on gaseous ammonia, is very curious. When potassium is fused in that gas, a very fusible olive-green substance, consisting of potassium, nitrogen, and ammonia, is formed; and a volume of hydrogen remains, exactly equal to what would result from the action on water of the quantity of potassium employed. Hence, according to Thenard, the ammonia is divided into two portions. One is decomposed, so that its nitrogen combines with the potassium, and its hydrogen remains free, whilst the other is absorbed in whole or in part by the nitroguret of potassium. Sodium acts in the same manner. The olive substance is opaque, and it is only when in plates of extreme thinness that it appears semitransparent; it has nothing of the metallic appearance; it is heavier than water; and, on minute inspection, seems imperfectly crystallised. When it is exposed to a heat progressively increased, it melts, disengages ammonia, and hydrogen, and nitrogen, in the proportions constituting ammonia; then it becomes solid, still preserving its green colour, and is converted into a nitroguret of potassium or sodium. Exposed to the air at the ordinary temperature, it attracts only its humidity, but not its oxygen, and is slowly transformed into ammoniacal gas, and potassa or soda. It burns vividly when projected into a hot crucible, or when heated in a vessel containing oxygen. Water and acids produce also sudden decomposition, with the extrication of heat. Alkalies or alkaline salts are produced. Alcohol likewise decomposes it with similar results. The preceding description of the compound of ammonia with potassium, as prepared by Gay Lussac and Thenard, was controverted by Sir H. Davy.

The experiments of this accurate chemist led to the conclusion, that the presence of moisture had modified their results. In proportion as more precautions are taken to keep every thing absolutely dry, so in proportion is less ammonia regenerated. He seldom obtained as much as 1-10 of the quantity absorbed; and he never could procure hydrogen and nitrogen in the proportions constituting ammonia; there was always an excess of nitrogen. The following experiment was conducted with the utmost nicety. 3½ gr. of potassium were heated in 12 cubic inches of ammoniacal gas; 7.5 were absorbed, and 3.2 of hydrogen evolved. On distilling the olive-coloured solid in a tube of platina, 9 cubical inches of gas were given off, and half a cubical inch remained in the tube and adapters. Of the 9 cubical inches, one-fifth of a cubical inch only was ammonia; 10 measures of the permanent gas mixed with 7.5 of oxygen, and acted upon by the electrical spark, left a residuum of 7.5. He infers that the results of the analysis of ammonia, by electricity and potassium, are the same.

On the whole we may legitimately infer, that there is something yet unexplained in these phenomena. The potassium separates from ammonia as much hydrogen, as an equal weight of it would from water. If two volumes of hydrogen be thus detached from the alkaline gas, the remaining volume, with the volume of nitrogen, will be left to combine with the potassium, forming a triple compound, somewhat analogous to the cyanides, a compound capable of condensing ammonia.

When ammoniacal gas is transmitted over ignited wires of iron, copper, platina, &c. it is decomposed completely, and though the metals are not increased in weight, they have become extremely brittle. Iron, at the same temperature, decomposes the ammonia, with double the rapidity that platinum does. At a high temperature, the protoxyde of nitrogen decomposes ammonia.

Of the ordinary metals, zinc is the only one which liquid ammonia oxydizes and then dissolves. But it acts on many of the metallic oxydes. At a high temperature the gas deoxydizes all those which are reducible by hydrogen. The oxydes soluble in liquid ammonia, are the oxyde of zinc; the protoxyde and peroxyde of copper; the oxyde of silver; the third and fourth oxydes of antimony; the oxyde of tellurium; the protoxydes of nickel, cobalt, and iron, the peroxyde of tin, mercury, gold, and platinum. The first five are very soluble, the rest less so. These combinations can be obtained by evaporation, in the dry state, only with copper, antimony, mercury, gold, platinum, and silver; the four last of which are very remarkable for their detonating property. See the particular metals.

All the acids are susceptible of combining with ammonia, and they almost all form with it neutral compounds. Gay Lussac made the important discovery, that whenever the acid is gaseous, its combination with ammoniacal gas takes place in a simple ratio of determinate volumes, whether a neutral or a subsalt be formed.

Ammoniacal salts have the following general characters:—

1st, When treated with a caustic fixed alkali or earth, they exhale the peculiar smell of ammonia.

2d, They are generally soluble in water, and crystallisable.

3d, They are all decomposed at a moderate red heat; and if the acid be fixed, as the phosphoric or boracic, the ammonia comes away pure.

4th, When they are dropped into a solution of muriate of platina, a yellow precipitate falls."—*Ure's Chem. Dic.*

The preparations of ammonia in use are,

1. Liquor ammoniæ. See *Ammoniæ liquor.*

2. The sub-carbonate of ammonia. See *Ammoniæ subcarbonas*, and *ammoniæ subcarbonatis liquor.*

3. The acetate of ammonia. See *Ammoniæ acetatis liquor.*

4. The muriate of ammonia. See *Sal ammoniac.*

5. Ferrum ammoniatum.

6. Several tinctures and spirits, holding ammonia in solution.

Ammonia, argentate of. Fulminating silver.

AMMONIA ACETATA. See *Liquor ammoniæ acetatis.*

AMMONIA MURIATA. See *Sal ammoniac.*

AMMONIA PRÆPARATA. See *Ammoniæ subcarbonas.*

AMMONIAC, SAL. See *Sal Ammoniac.*

AMMONI'ACUM. (Αμμονιακον; so called from *Ammonia*, whence it was brought.) *Gum-ammoniac.* A concrete gummy resinous juice, composed of little lumps, or tears, of a strong and somewhat ungrateful smell, and nauseous taste, followed by a bitterness. There has, hitherto, been no information had concerning the plant which affords this drug; but Wildenow considers it to be the *Heracleum gummiferum*, having raised that plant from the seeds, which are sometimes found in the drug. It is imported here from Turkey, and from the East Indies. It consists, according to Braconnot, of 70 resin, 18.4 gum, 4.4 glutinous matter, 6 water, and 1.2 loss in 100 parts. Gum ammoniacum is principally employed as an expectorant, and is frequently prescribed in asthma and chronic catarrh. Its dose is from 10 to 30 grains. It is given in the form of pill or diffused in water, and is frequently combined with squill, or tartarised antimony. In large doses, it proves purgative. Externally, it is applied as a discutient, under the form of plaster, to white swellings of the knee, and to indolent tumours. The official preparations are Ammoniacum purificatum; Emplastrum ammoniaci; Empl. ammoniaci cum hydrargyro; Mistura ammoniaci.

Ammoniæ acetatis liquor. A solution of acetate of ammonia; formerly called *Aqua ammoniæ acetatæ.* Take of sub-carbonate of ammonia, two ounces; dilute acetic acid, four pints. Add the acid to the salt, until bubbles of gas shall no longer arise, and mix. The effervescence is occasioned by the escape of carbonic acid gas, which the acetic acid expels, and neutralises the ammonia.

If the acid rather predominate, the solution is more grateful to the taste; and provided that acid be correctly prepared, the proportions here given will be found sufficient; where the acid cannot be depended on, it will be right to be regulated rather by the cessation of effervescence than by quantity.

This preparation was formerly known in the shops under the name of *spirit of Mindererus.* When assisted by a warm regimen, it proves an excellent and powerful sudorific; and, as it operates without quickening the circulation, or increasing the heat of the body, it is admissible in febrile and inflammatory diseases, in which the use of stimulating sudorifics are attended with danger. Its action may likewise be determined to the kidneys, by walking about in the cool air. The common dose is half an ounce, either by itself, or along with other medicines, adapted to the same intention.

Ammoniæ carbonas. See *Ammoniæ subcarbonas.*

Ammoniæ liquor. *Liquor of Ammonia.* Take of muriate of ammonia eight ounces; lime newly prepared, six ounces; water, four pints. Pour on the lime a pint of the water, then cover the vessel, and set them by for an hour; then add the muriate of ammonia, and the remaining water previously made boiling hot, and cover the vessel again; strain the liquor when it has cooled; then distil from it twelve fluid ounces of the solution of ammonia into a receiver cooled to the temperature of 50°. The specific gravity of this solution should be to that of distilled water, as 4.960 to 1000.

Lime is capable of decomposing muriate of ammonia at a temperature much below that of boiling water; so that when the materials are mixed, a solution of ammonia and of muriate of lime is obtained. This being submitted to distillation, the ammonia passes over with a certain portion of the water, leaving behind the muriate of lime dissolved in the rest. The proportion of water directed seems, however, unnecessarily great, which obliges the operator to employ larger vessels than would otherwise suffice. But the process now directed is certainly much easier, more economical, and more uniform in its results, than that of former Pharmacopœias.

This preparation is colourless and transparent with a strong peculiar smell; it parts with the ammonia in the form of gas, if heated to 130 degrees, and requires to be kept, with a cautious exclusion of atmospherical air, with the carbonic acid of which it readily unites: on this latter account, the propriety of keeping it in small bottles instead of a large one, has been suggested.

This is the *aqua ammoniæ puræ* of the shops, and the *alcali volatile causticum.*

Water of ammonia is very rarely given internally, although it may be used in doses of ten or twenty drops, largely diluted, as a powerful stimulant in asphyxia and similar diseases. Externally, it is applied to the skin as a rubefacient, and in the form of gas to the nostrils, and to the eyes as a stimulant: in cases of torpor, paralysis, rheumatism, syncope, hysteria, and chronic ophthalmia.

Ammoniæ murias. See *Sal ammoniacæ.*

Ammoniæ nitras. *Alcali volatile nitratum; Sal ammoniacus nitrosus; Ammonia nitrata.* A salt composed of the nitric acid and ammonia, the virtues of which are internally diuretic and deobstruent, and externally resolvent and sialogogue.

Ammoniæ subcarbonas. Subcarbonate of ammonia. This preparation was formerly called *ammonia præparata,* and *sal volatilis salis ammoniaci,* and *sal volatilis.* It is made thus:—Take of muriate of ammonia, a pound: of prepared chalk, dried, a pound and a half. Reduce them separately to powder; then mix them together, and sublime in a heat gradually raised, till the retort becomes red. In this preparation a double decomposition takes place, the carbonic acid of the chalk uniting with the ammonia, and forming subcarbonate of ammonia, which is volatilised while muriate of lime remains in the vessel.

This salt possesses nervine and stimulating powers, and is highly beneficial in the dose of from two to eight grains, in nervous affections, debilities, flatulency, and acidity from dyspepsia.

Ammoniæ subcarbonatis liquor. *Liquor ammoniæ carbonatis.* Solution of subcarbonate of ammonia. Take of subcarbonate of ammonia, four ounces; distilled water a pint. Dissolve the subcarbonate of ammonia in the water, and filter the solution through paper. This preparation possesses the properties of ammonia in its action on the human body. See *Ammoniæ subcarbonas.*

Ammonicated copper, liquor of. See *Cupri ammoniati liquor.*

Ammo'nion. (From αμμος, sand.) Aëtius uses this term to denote a collyrium of great virtue in many diseases of the eye, which was said to remove sand or gravel from the eyes.

AMMONI'TES. Petrifactions, which have likewise been distinguished by the name of *cornua ammonis,* and are called *snake-stones* by the vulgar, consist chiefly of lime-stone. They are found of all sizes, from the breadth of half an inch to more than two feet in diameter; some of them rounded, others greatly compressed, and lodged in different strata of stones and clays. They appear to owe their origin to shells of the nautilus kind.

AMMO'NIUM. Berzelius first gave this name to a supposed metal which with oxygen he conceives to form the alkali called ammonia. It is now generally used by all chemists. See *Ammonia.*

AMNE'SIA. (From α, priv. and μνησις, memory.) *Amnestia.* Forgetfulness; mostly a symptomatic affection.

Amne'stia. See *Amnesia.*

A'MNIOS. (From αμνος a lamb, or lamb's skin.) *Amnion.* The soft internal membrane which surrounds the fœtus. It is very thin and pellucid in the early stage of pregnancy, but acquires considerable thickness and strength in the latter months. The amnios contains a thin watery fluid, in which the fœtus is suspended. See *Liquor amnii.*

AMNIOTIC. (*Amnioticus;* from *amnios:* so called because it is obtained from the membrane of that name.) Of or belonging to the amnios.

Amniotic acid. *Acidum amnioticum.* A

peculiar acid found in the liquor of the amnios of the cow. It exists in the form of a white pulverulent powder. It is slightly acid to the taste, but sensibly reddens vegetable blues. It is with difficulty soluble in cold, but readily soluble in boiling water, and in alcohol. When exposed to a strong heat, it exhales an odour of ammonia and of prussic acid. Assisted by heat, it decomposes carbonate of potassa, soda, and ammonia. It produces no change in the solutions of silver, lead, or mercury, in nitric acid. Amniotic acid may be obtained by evaporating the liquor of the amnios of the cow to a fourth part, and suffering it to cool; crystals of amniotic acid will be obtained in considerable quantity. Whether this acid exists in the liquor of the amnios of other animals, is not yet known.

AMO'MUM. (*Amomum*, *i.* n.; from an Arabian word, signifying a pigeon, the foot of which it was thought to resemble.) The name of a genus of plants in the Linnæan system. Class *Monandria*; Order, *Monogynia*.

AMOMUM CARDAMOMUM. The former systematic name for the *cardamomum minus*. See *Elettaria cardamomum*.

AMOMUM GRANUM PARADISI. The systematic name of the plant which affords the grains of paradise. *Cardamomum majus*; *Meleguetta*; *Maniguetta*; *Cardamomum piperatium*. Grains of paradise, or the greater cardamom seeds are contained in a large brown, somewhat triangular flask, the thickness of one's thumb and pyramidal. The seeds are angular, and of a reddish brown colour, smaller than pepper, and resemble very much the seeds of the *cardamomum minus*. They are extremely hot, and similar in virtue to pepper.

AMOMUM VERUM. True stone parsley. The fruit is about the size of a grape, of a strong and grateful aromatic taste, and penetrating smell. The seeds have been given as a carminative.

AMOMUM ZINGIBER. The former systematic name of the plant which affords ginger. See *Zingiber officinale*.

AMO'RGE. See *Amurca*.

AMPELITE. The aluminous ampelite, is the alum slate; and the graphic, the graphic slate.

AMPELOSA'GRIA. (From αμπελος, a vine, and αγριος, wild.) See *Bryonia alba*.

AMPHEMERI'NA. See *Amphemerinos*.

AMPHEMERI'NOS. (From αμφι, about, and ημερα, a day.) *Amphemerina*. A fever of one day's duration.

AMPHIARTHRO'SIS. Αμφιαρθρωσις; from αμφι, both, and αρθρωσις, an articulation: so called from its partaking both of diarthrosis and synarthrosis.) A mixed species of connexion of bones, which admits of an obscure motion, as is observed in the metacarpal and metatarsal bones, and the vertebræ.

AMPHIBIUM. (From αμφι, *ambo*, and βιος, vita.) An amphibious animal, or one that lives both on land and in the water. The *amphibious* animals, according to Linnæus, are a class, the heart of which is furnished with one ventricle and one auricle, in which respiration is in a considerable degree voluntary.

AMPHIBLESTROI'DES. (From αμφιβληςρον, a net, and ειδος, a resemblance.) Reteform or net-like; a term which has been applied to the retina.

APHIBOLE. Some species of actionlite and hornblende have this name.

AMPHIBOLITES. Trap rocks are so called in geology, the basis of which is hornblende.

AMPHIBRA'NCHIA. (From αμφι, about, and βραγχια, the jaws.) The fauces or parts about the tonsils, according to Hippocrates and Foësius.

AMPHICAU'STIS. (From αμφι, about, and καυςις, ripe corn.) 1. A sort of wild barley.

2. Eustachius says, it was also to express the private parts of a woman.

AMPHIDEON. (From αμφι, on both sides, and δαιω, to divide.) *Amphidæum*; *Amphidium*. The os tincæ, or mouth of the womb, which opens both ways, was so called by the ancients.

AMPHIDIARTHRO'SIS. The same as *Amphiarthrosis*.

AMPHIGENE. A name of Vesuvian.

AMPHIMERI'NA. (From αμφι, about, and ημερα, a day.) A fever of one day's continuance.

AMPHIME'TRION. From αμφι, about, and μητρα, the womb.) *Amphimetrium*. The parts about the womb. *Hippocrates*.

A'MPHIPLEX. (From αμφι, about, and ῶλεκτω, to connect.) According to Rufus Ephesius, the part situated between the scrotum and anus, and which is connected with the thighs.

AMPHIPNEU'MA. (From αμφι about, and ῶνευμα, breath.) A difficulty of breathing.—*Hippocrates*.

AMPHI'POLOS. (From αμφι, about, and ῶολεω, to attend. (*Amphipolus*. One who attends the bed of a sick person, and administers to him. —*Hippocrates*.

AMPHISMI'LA. (From αμφι, on both sides, and σμιλη, an incision-knife.) A dissecting knife, with an edge on both sides. *Galen*.

AMPLECTENS. Embracing, clasping.

AMPLEXICAULIS. (From *amplector*, to surround, and *caulis*, a stem.) Embracing or clasping the stem. *Folium amplexicaule* is a leaf, the base of which surrounds the stem, as in *Papaver somniferum* and *Carduus marianus*; and the *Senecio hirsutus*, has a leafstalk which embraces the stem at its base.

AMPU'LLA. Αμβολλα; from αναβαλλω, to swell out.) A bottle.

1. All bellied vessels are so called in chemistry, as bolt-heads, receivers, cucurbits, &c.

2. In anatomy this term is applied by Scarpa to the dilated portions of the membranaceous semicircular canals, just within the vestibulum of the ear.

3. In botany; it is a small membranaceous bag attached to the roots and the emersed leaves of some aquatic plants, rendering them buoyant.—*Thompson*.

AMPULLE'SCENS. (From *ampulla*, a bottle.) The most tumid part of the thoracic duct is called *alveus ampullescens*.

AMPUTA'TIO. (From *amputo*, to cut off.) *Ectome*. Amputation; a surgical operation, which consists in the removal of a limb or viscus: thus we say, a leg, a finger, the penis, &c. when cut off, are amputated; but when speaking of a tumour or excrescence, it is said to be removed, or dissected out.

AMULE'TUM. (From αμμα, a bond; because it was tied round the person's neck; or rather from αμυνω, to defend.) An amulet, or charm; by wearing which the person was supposed to be defended from the admission of all evil: in particular, an antidote against the plague.

AMU'RCA. (From αμεργω, to press out.) *Amorge*. 1. A small herb, whose expressed juice is used in dieing.

2. The sediment of the olive, after the oil has been pressed from it; recommended by Hippocrates and Galen as an application to ulcers.

AMU'TICA. (From *αμυττω*, to scratch.) Medicines that, by vellicating or scratching, as it were, the bronchia, stimulate it to the discharge of whatever is to be thrown off the lungs.

A'MYCHE. (From *αμυσσω*, to scratch.)

1. A superficial laceration or exulceration of the skin: a slight wound.—*Hippocrates.*

2. Scarification.—*Galen.*

AMY'CTCIA. (From *αμυσσω*, to vellicate.) Medicines which stimulate and vellicate the skin, according to Cœlius Aurelianus.

AMY'GDALA. (*Amygdala, æ. f.*; Αμυγδαλη; from *αμυσσω*, to lancinate: so called, because after the green husk is removed from the fruit, there appear upon the shell certain fissures, as it were lacerations.)

1. The fruit called the almond. See *Amygdalus communis.*

2. The tonsil glands of the throat are sometimes termed, from their resemblance, *Amygdalæ.*

AMYGDALA AMARA. The bitter almond. See *Amygdalus communis.*

AMYGDALA DULCIS. The sweet almond. See *Amygdalus communis.*

AMYGDALÆ OLEUM. See *Amygdalus communis.*

AMYGDALOID. (*Amygdaloides*; from *amygdalus*, an almond, and *ειδος*, resemblance.) Almond-like.

1. A name given to some parts of the body and to parts of vegetables and minerals, which resemble almonds.

2. A compound mineral consisting of spheroidal particles or vesicles of lithomarge, green earth, calc spar, steatite imbedded in a basis of fine-grained green-stone or wacke, containing sometimes, also, crystals of hornblende.

AMY'GDALUS. (*Amygdalus, i. m.*; from *amygdala*, the derivation of which look to.) The name of a genus of plants in the Linnæan system. Class, *Icosandria*; Order, *Monogynia*. The almond-tree.

AMYGDALUS COMMUNIS. The systematic name of the plant which affords the common almond. *Amygdalus—foliis serratis infimis glandulosis, floribus sessilibus geminis* of Linnæus.

The almond is a native of Barbary. The same tree produces either bitter or sweet. Sweet almonds are more in use as food than medicine; but they are said to be difficult of digestion, unless extremely well comminuted. Their medicinal qualities depend upon the oil which they contain in the farinaceous matter, and which they afford on expression, nearly in the proportion of half their weight. It is very similar to olive oil; perhaps rather purer, and is used for the same purposes. The oil thus obtained is more agreeable to the palate than most of the other expressed oils, and is therefore preferred for internal use, being generally employed with a view to obtund acrid juices, and to soften and relax the solids, in tickling coughs, hoarseness, costiveness, nephritic pains, &c. Externally, it is applied against tension and rigidity of particular parts. The milky solutions of almonds in watery liquors, usually called emulsions, possess, in a certain degree, the emollient qualities of the oil, and have this advantage over pure oil, that they may be given in acute or inflammatory disorders, without danger of the ill effects which the oil might sometimes produce by turning rancid. The officinal preparations of almonds are the expressed oil, the confection, and the emulsion; to the latter, the addition of gum-arabic is sometimes directed, which renders it a still more useful demulcent in catarrhal affections, stranguries, &c.

Bitter almonds yield a large quantity of oil, perfectly similar to that obtained from sweet almonds, but the matter remaining after the expression of the oil, is more powerfully bitter than the almond in its entire state. Great part of the bitter matter dissolves by the assistance of heat, both in water and rectified spirit; and a part arises also with both menstrua in distillation. Bitter almonds have been long known to be poisonous to various brute animals; and some authors have alleged that they are also deleterious to the human species; but the facts recorded upon this point appear to want further proof. However, as the noxious quality seems to reside in that matter which gives it the bitterness and flavour, it is very probable, that when this is separated by distillation, and taken in a sufficiently concentrated state, it may prove a poison to man, as is the case with the common laurel, to which it appears extremely analogous. Bergius tells us, that bitter almonds, in the form of emulsion, cured obstinate intermittents, after the bark had failed. A simple water is distilled from bitter almonds, after the oil is pressed out, which possesses the same qualities, and in the same degree, as that drawn from cherry-stones. These afforded, formerly, the now-exploded *aqua cerasorum nigrorum*, or black cherry-water.

AMYGDALUS PERSICA. The systematic name of the common peach-tree. The fruit is known to be grateful and wholesome, seldom disagreeing with the stomach, unless this organ is not in a healthy state, or the fruit has been eaten to excess, when effects similar to those of the other dulco-acid summer fruits may be produced. The flowers, including the calyx as well as the corolla, are the parts of the persica used for medicinal purposes. These have an agreeable, but weak smell, and a bitterish taste. Boulduc observes, "that when distilled, without addition, by the heat of a water-bath, they yield one-sixth their weight, or more, of a whitish liquid, which communicates to a considerable quantity of other liquids a flavour like that of the kernels of fruits. These flowers have a cathartic effect, and, especially to children, have been successfully given in the character of a vermifuge; for this purpose, an infusion of a dram of the flowers dried, or half an ounce in their recent state, is the requisite dose. The leaves of the peach are also found to possess anthelmintic power, and from a great number of experiments appear to have been given with invariable success, both to children and adults. However, as the leaves and flowers of this plant manifest, in some degree, the quality of those of the laurocerasus, they ought to be used with caution."

A'MYLA. (From *amylum*, starch.) This term has been applied to some chemical fæcula, or highly pulverized residuum. Obsolete.

AMY'LEON. *Amylion.* Starch.

A'MYLUM. (*Amylum, i. n.* Αμυλον; from *α*, priv. and *μυλη*, a mill; because it was formerly made from wheat, without the assistance of a mill.) *Amyleon*; *Amylion.* See *Starch.*

AMY'RIS. (From *α*, intensive, and *μυρον*, ointment, or balm; so called from its use, or smell.) The name of a genus of plants in the Linnæan system. Class, *Octandria*; Order, *Monogynia*, of which two species are used in medicine.

AMYRIS ELEMIFERA. The systematic name of the plant from which it is supposed we obtain the resin called *gum-elemi.* The plant is described by Linnæus: *Amyris:—foliis ternis quinato pinnatisque subtus tomentosis.* Elemi is brought here from the Spanish West Indies:

it is most esteemed when softish, somewhat transparent, of a pale whitish colour, inclining a little to green, and of a strong, though not unpleasant smell. It is only used in ointments and plasters, and is a powerful digestive.

AMYRIS GILEADENSIS. The systematic name of the plant from which the *opobalsamum* is obtained. It has been called by a variety of names, as *Balsamum genuinum antiquorum; Balsamelæon; Ægyptiacum balsamum; Balsamum Asiaticum; Balsamum Judaicum; Balsamum Syriacum; Balsamum e Mecca; Balsamum Alpini; Oleum balsami; Carpobalsamum; Xylobalsamum.* Balsam, or balm of Gilead; Balsam of Mecca. A resinous juice, obtained by making incisions into the bark of the *Amyris:—foliis ternatis integerrimis, pedunculis unifloris lateralibus* of Linnæus. This tree grows spontaneously, particularly near to Mecca, on the Asiatic side of the Red Sea. The juice of the fruit is termed *carpobalsamum* in the pharmacopœias, and that of the wood and branches *xylobalsamum.* The best sort is a spontaneous exudation from the tree, and is held in so high estimation by the Turks, that it is rarely, if ever, to be met with genuine among us. The medicinal virtues of the genuine balsam of Gilead, have been highly rated, undoubtedly with much exaggeration. The common balsam of Mecca is scarcely used; but its qualities seem to be very similar to those of the balsam of Tolu, with perhaps more acrimony. The dose is from 15 to 50 drops.

A′MYUM. (From *α*, priv. and *μυς*, muscle.) A limb so emaciated that the muscles scarcely appear.

ANA. In medical prescriptions it means "of each." See *A.*

ANA′BASIS. (From *αναβαινω*, to ascend.)

1. An ascension, augmentation, or increase of a disease, or paroxysm. It is usually meant of fevers.—*Galen.*

2. A species of the *equisetum* or horse-tail plant.

ANABA′TICA. (From *αναβαινω*, to ascend.) An epithet formerly applied to a continual fever, when it increases in malignity.

ANABE′XIS. (From *αναβηττω*, to cough up.) An expectoration of matter by coughing.

ANABLE′PSIS. (From *ανα* and *βλεπω*, to see again.) The recovery of sight after it has been lost.

ANABLYSIS. (From *ανα* and *βλυζω*, to gush out again.) Ebullition or effervescence.

ANA′BOLE. (From *αναβαλλω*, to cast up.) The discharge of any thing by vomit; also dilatation, or extension.—*Galen.*

ANABROCHE′SIS. (From *ανα* and *βροχεω*, to reabsorb.) The reabsorption of matter.

ANABROCHI′SMOS. (From *αναβροχεω*, to reabsorb.) *Anabrochismus.* The taking up and removing the hair on the eyelids, when they become troublesome.—*Galen, Ægineta,* and others.

ANABRO′SIS. (From *αναβροσκω*, to devour.) A corrosion of the solid parts, by sharp and biting humours.—*Galen.*

ANACA′RDIUM. (From *ανα*, without, and *καρδια*, a heart.) Without heart; because the pulp of the fruit, instead of having the seed enclosed, as is usually the case, has the nut growing out of the end of it. The name of a genus of plants. Class, *Enneandria;* Order, *Monogynia.*

ANACARDIUM OCCIDENTALE. The cashew-nut. The oil of this nut is an active caustic, and employed as such in its native country; but neither it, nor any part of the fruit, is used medicinally in this country. It is a useful marking ink, as any thing written on linen or cotton with it, is of a brown colour, which gradually grows blacker, and is very durable.

ANACARDIUM ORIENTALE. The Malacca bean. See *Avicennia tomentosa.*

ANACATHA′RSIS. (From *ανα*, and *καθαιρομαι*, to purge up.) An expectoration of pus, or a purgation by spitting, contra-distinguished from catharsis, or evacuation downwards. In this sense the word is used by Hippocrates and Galen. Blanchard denotes, by this word, medicines which operate upwards, as vomiting, &c.

ANACATHA′RTIC. (*Anacatharticus;* from *ανακαθαιρομαι*, to purge upwards.) Promoting expectoration, or vomiting.

ANA′CHRON. Mineral alkali.

ANA′CLASIS. (From *ανακλαω*, to bend back.) A reflection or recurvature of any of the members, according to Hippocrates.

ANA′CLISIS. (From *ανακλενω*, to recline.) A couch, or sick bed.—*Hippocrates.*

ANACO′CHE. (From *ανακωχεω*, to retard.) Delay in the administration of medicines; also slowness in the progress of a disease.—*Hippocrates.*

ANACŒLIA′SMUS. (From *ανα*, and *κοιλια*, the bowels.) A gentle purge, which was sometimes used to relieve the lungs.

ANACOLLE′MA. (From *ανα*, and *κολλαω*, to glue together.) A collyrium made of agglutinant substances, and stuck on the forehead.—*Galen.*

ANACONCHOLI′SMOS. (From *ανακογχολιζω*, to sound as a shell.) A gargarism: so called, because the noise made in the throat is like the sound of a shell.—*Galen.*

ANACTE′SIS. (From *ανακταομαι*, to recover.) Restoration of strength; recovery from sickness.—*Hippocrates.*

ANACUPHI′SMA. (From *ανακουφιζω*, to lift up.) A kind of exercise mentioned by Hippocrates, which consists in lifting the body up and down, like our weigh jolt, and dumb bells.

ANACYCE′SIS. (From *ανακυκαω*, to mix.) The mixture of substances, or medicines, by pouring one upon another.

ANACY′CLEON. (From *ανακυκλοω*, to wander about.) *Anacycleus.* A mountebank, or wandering quack.

ANACYRI′OSIS. (From *ανα*, and *κυρος*, authority.) By this word, Hippocrates means that gravity and authority which physicians should preserve among sick people and their attendants.

ANADIPLO′SIS. (From *αναδιπλοω*, to reduplicate.) A reduplication or frequent return of a paroxysm, or disease.—*Galen.*

ANA′DOSIS. (From *ανω*, upwards, and *διδωμι*, to give.) 1. A vomit.

2. The distribution of aliment all over the body.

3. Digestion.

ANA′DROME. (From *ανω*, upwards, and *δρεμω*, to run.) A pain which runs from the lower extremities to the upper parts of the body.—*Hippocrates.*

ANÆ′DES. (From *α*, priv. and *αιδως*, shame.) Shameless. Hippocrates uses this word metaphorically for without restraint; and applies it to water rushing into the aspera arteria.

ANÆSTHE′SIA. (*Anæsthesia, æ.* f. *Αναισθησια;* from *α*, priv. and *αισθανομαι*, to feel.) Loss of the sense of touch. A genus of disease in the class *Locales,* and order *Dysæsthesiæ* of Cullen.

ANAGA′LLIS. (From *αναγελαω*, to laugh; because, by curing the spleen, it disposes persons to be cheerful.) 1. The name of a genus of plants in the Linnæan system.

2. The pharmacopœial name of the *anagallis arvensis.*

ANAGALLIS ARVENSIS. The systematic name for the *Anagallis—foliis indivisis, caule procumbente* of Linnæus. A small and delicately formed plant, which does not appear to possess any particular properties.

ANAGARGALI'CTUM. (From *ανα*, and *γαῤγαρεων*, the throat.) A gargarism, or wash for the throat.

ANAGARGARI'STUM. A gargle.

ANAGLY'PHE. (From *αναγλυφω*, to engrave.) A part of the fourth ventricle of the brain was formerly thus called, from its resemblance to a pen, or style.

ANAGNO'SIS. (From *αναγινωσκω*, to know.) The persuasion, or certainty, by which medical men judge of a disease from its symptoms.—*Hippocrates.*

ANA'GRAPHE. (From *αναγραφω*, to write.) A prescription or receipt.

ANALCINE. Cubic zeolite. A mineral found in granite, gneiss, trap rocks, and lavas, at Calton Hill, Edinburgh, in Bohemia and Ferroe islands. From its becoming *feebly* electrical by heat, it has got this name.

ANALE'NTIA. A fictitious term used by Paracelsus for epilepsy.

ANALE'PSIA. (From *ανα*, and *λαμβανω*, to take again.) A species of epilepsy, which proceeds from a disorder of the stomach, and with which the patient is apt to be seized very often and suddenly.

ANALE'PSIS. (From *αναλαμβανω*, to restore.) A recovery of strength after sickness.

ANALE'PTIC. (*Analepticus ;* from *αναλαμβανω*, to recruit or recover.) That which recovers the strength which has been lost by sickness.

ANALO'SIS. (From *αναλισκω*, to consume.) A consumption, or wasting.

ANA'LYSIS. (*Αναλυσις* ; from *αναλυω*, to resolve.) The resolution by chemistry, of any matter into its primary and constituent parts. The processes and experiments which chemists have recourse to, are extremely numerous and diversified, yet they may be reduced to two species, which comprehend the whole art of chemistry. The first is, *analysis*, or decomposition ; the second, *symthesis*, or composition. In *analysis*, the parts of which bodies are composed, are separated from each other : thus, if we reduce cinnabar, which is composed of sulphur and mercury, and exhibit these two bodies in a separate state, we say we have decomposed or analysed cinnabar. But if, on the contrary, several bodies be mixed together, and a new substance be produced, the process is then termed chemical composition, or *synthesis* : thus, if by fusion and sublimation, we combine mercury with sulphur, and produce cinnabar, the operation is termed chemical composition, or composition by synthesis. Chemical analysis consists of a great variety of operations. In these operations the most extensive knowledge of such properties of bodies as are already discovered must be applied, in order to produce simplicity of effect, and certainty in the results. Chemical analysis can hardly be executed with success, by one who is not in possession of a considerable number of simple substances, in a state of great purity, many of which, from their effects, are called reagents. The word analysis is often applied by chemists to denote that series of operations, by which the component parts of bodies are determined, whether they be merely separated, or exhibited apart from each other ; or whether these distinctive properties be exhibited by causing them to enter into new combinations, without the perceptible intervention of a separate state ; and, in the chemical examination of bodies, analysis or separation can scarcely ever be effected, without synthesis taking place at the same time.

ANAMNE'SIS. (From *αναμιμνησκω*, to remember.) Remembrance, or recollection of what has been done.—*Galen.*

ANAMNE'STIC. (From the same.) A remedy for bad memory, or whatever strengthens the memory.

ANA'NAS. The egg-shaped pine-apple. See *Bromelia Ananas.*

ANA'NCE. (From *αναγκαζω*, to compel.) Necessity. It is applied to any desperate operation.—*Hippocrates.*

ANAPHALANTI'ASIS. (From *αναφαλαντος*, bald.) A thinness of hair upon the eye-brows. —*Gorræus.*

ANA'PHORA. (From *αναφερω*, to bring up.) It is applied to a person who spits blood.—*Gorræus.*

ANAPHORY'XIS. (From *αναφορυσσω*, to grind down.) The reducing of any thing to dust, or a very fine powder.

ANAPHRODI'SIA. (*Anaphrodisia, æ. f.* ; from *α*, priv. and *αφροδισια*, the feast of Venus.) Impotence. A genus of disease in the class *Locales*, and order *Dysorexiæ* of Cullen. It either arises from paralysis, *anaphrodisia paralytica ;* or from gonorrhœa, *anaphrodisia gonorrhoica.*

ANAPHRO'MELI. (From *α*, neg. *αφρος*, froth, and *μελι*, honey.) Clarified honey.

ANAPLA'SIS. (From *αναπλασσω*, to restore again.) A restoration of flesh where it has been lost ; also the reuniting a fractured bone.—*Hippocrates*

ANAPLERO'SIS. (From *αναπληροω*, to fill again.) The restitution, or filling up of wasted parts.—*Galen.*

ANAPLERO'TICA. (From the same.) Medicines renewing flesh : incarnatives, or such medicines as fill up a wound so as to restore it to its original shape.—*Galen.*

ANAPLEU'SIS. (From *αναπλευω*, to float upon.) The rotting of a bone, so that it drops off, and lies upon the flesh. Exfoliation, or separation of a bone.—*Hippocrates, Ægineta,* &c.

ANAPNEU'SIS. (From *αναπνεω*, to respire.) Respiration.

ANA'PNOE. Respiration.

ANAPTO'SIS. (From *αναπιπτω*, to fall back.) A relapse.

ANA'PTYSIS. The same as *Anacatharsis.*

ANARRHEGNI'MIA. (From *ανα*, and *ῥηγνυμι*, to break again.) *Anarrhexis.* A fracture, the fresh opening of a wound.

ANARRHŒ'A. (From *ανα*, upwards, and *ῥεω*, to flow.) A flux of humours from below upwards.—*Schneider de Catarrho.*

ANARRHO'PIA. (From *ανα*, upwards, and *ῥεπω*, to creep.) A flux of humours from below upwards.—*Hippocrates.*

A'NAS. (*Anas, tis.* f. ; from *νεω*, to swim, *a nando.*) A genus of birds in the Linnæan system.

ANAS CYGNUS. The swan. The flesh of the young swan or cygnet is tender, and a great delicacy.

ANAS DOMESTICA. The tame duck. The flesh of this bird is difficult of digestion, and requires that warm and stimulating condiments be taken with it to enable the stomach to digest it.

ANASA'RCA. *Anasarca, æ. f.* ; from *ανα*, through, and σαρξ, flesh.) *Sarcites.* A species of dropsy from a serous humour, spread between the skin and flesh, or rather a general accumulation of lymph in the cellular system. Dr. Cullen ranks this genus of disease in the class *Cachexiæ*, and the order *Intumescentiæ.* He enumerates the following species, viz, 1. *Anasarca serosa:* as when the due discharge of serum is suppressed, &c. 2. *Anasarca oppilata:* as when the blood-vessels are considerably pressed, which happens to many pregnant women, &c. 3. *Anasarca exanthematica:* this happens after ulcers, various eruptive disorders, and particularly after the *erysipelas.* 4. *Anasarca anœmia* happens when the blood is rendered extremely poor from considerable losses of it. 5. *Anasarca debilium:* as when feebleness is induced by long illness, &c.

This species of dropsy shows itself at first with a swelling of the feet and ancles towards the evening, which, for a time, disappears again in the morning. The tumefaction is soft and inelastic, and, when pressed upon by the finger, retains its mark for some time, the skin becoming much paler than usual. By degrees the swelling ascends upwards, and occupies the trunk of the body; and at last, even the face and eyelids appear full and bloated; the breathing then becomes difficult, the urine is small in quantity, high-coloured, and deposits a reddish sediment; the belly is costive, the perspiration much obstructed, the countenance yellow, and a considerable degree of thirst, with emaciation of the whole body, prevails. To these symptoms succeed torpor, heaviness, a troublesome cough, and a slow fever. In some cases the water oozes out, through the pores of the cuticle; in others, being too gross to pass by these, it raises the cuticle in small blisters; and sometimes the skin, not allowing the water to escape through it, is compressed and hardened, and is, at the same time, so much distended as to give the tumour a considerable degree of firmness. For the causes of this disease, see *Hydrops.*

In those who have died of Anasarca, the whole of the cellular membrane has been distended with a fluid, mostly of a serous character. Various organic diseases have occurred; and the blood is said to be altered in consistence, according to the degree of the disease. In general a cure can be more readily affected when it arises from topical or general debility, than when occasioned by visceral obstruction; and in recent cases, than in those of long continuance. The skin becoming somewhat moist, with a diminution of thirst, and increased flow of urine, are very favourable. In some few cases the disease goes off by a spontaneous crisis by vomiting, purging, &c. The indications of treatment in anasarca are, 1. To evacuate the fluid already collected. 2. To prevent its returning again. The first object may be attained mechanically by an operation; or by the use of those means, which increase the action of the absorbents: the second by removing any exciting causes, which may still continue to operate; and at the same time endeavouring to invigorate the system. Where the quantity of fluid collected is such, as to disturb the more important functions, the best mode of relieving the patient is to make a few small incisions with a lancet, not too near each other, through the integuments on the fore and upper part of each thigh; the discharge may be assisted by pressure, and when a sufficient quantity has been evacuated, it is better to heal them by the first intention. In the use of issues or blisters, there is some risk of inducing gangrene, especially if applied to the legs: and the same has happened from scarifications with the cupping instrument. Absorption may be promoted by friction, and bandaging the parts, which will at the same time obviate farther effusion; but most powerfully by the use of different evacuating remedies, especially those which occasion a sudden considerable discharge of fluids. Emetics have been often employed with advantage; but it is necessary to guard against weakening the stomach by the frequent repetition of those which produce much nausea; and perhaps the benefit results not so much from the evacuation produced by the mouth, as from their promoting other excretions; antimonials in particular inducing perspiration, and squill increasing the flow of urine, &c.; for which purpose they may be more safely given in smaller doses: in very torpid habits, mustard may claim the preference. Cathartics are of much greater and more general utility; where the bowels are not particularly irritable, the more drastic purgatives should be employed, and repeated as often as the strength will allow; giving, for example, every second or third morning jalap, scammony, colocynth or gamboge, joined with calomel or the supertartrate of potassa, and some aromatic, to obviate their griping. Elaterium is perhaps the most powerful, generally vomiting as well as purging the patient, but precarious in its strength, and therefore better given in divided doses, till a sufficient effect is produced. Diuretics are universally proper, and may be given in the intervals, where purgatives can be borne, otherwise constantly persevered in; but unfortunately the effects of most of them are uncertain. Saline substances in general appear to stimulate the kidneys, whether acid, alkaline, or neutral; but the acetate, and supertartrate of potassa, are chiefly resorted to in dropsy. Dr. Ferriar, of Manchester, has made an important remark of the latter salt, that its diuretic power is much promoted by a previous operation on the bowels, which encourages the more liberal use of it; indeed, if much relied upon, a drachm or two should be given three times or oftener in the day. It is obviously, therefore, best adapted to those cases, in which the strength is not greatly impaired; and the same holds with the nauseating diuretics, squill, colchicum, and tobacco. The latter has been strongly recommended by Dr. Fowler of York, in the form of tincture; the colchicum, as an oxymel by some German physicians; but the squill is most in use, though certainly very precarious if given alone. In languid and debilitated habits, we prefer the more stimulant diuretics, as juniper, horseradish, mustard, garlic, the spiritus ætheris nitrici, &c.; even turpentine, or the tinctura cantharidis, may be proper, where milder means have failed. Digitalis is often a very powerful remedy, from the utility of which in inflammatory diseases we might expect it to answer best in persons of great natural strength, and not much exhausted by the disorder; but Dr. Withering expressly states that its diuretic effects appear most certainly and beneficially, where the pulse is feeble or intermitting, the countenance pale, the skin cold, and the tumours readily pitting on pressure; which has been since confirmed by other practitioners: it should be begun with in small doses two or three times a day, and progressively increased till the desired operation on the kidneys ensues, unless alarming symptoms appear in the meantime. Opium and some other narcotics have been occasionally useful as diuretics in dropsy, but should be only regarded as adjuvants, from their uncertain effects. In the use of diuretics, a very important rule is, not to restrict the patient from drinking freely. This was formerly thought necessary on theoretical grounds; whereby the thirst was aggravated to a distressing degree, and the operation of remedies often prevented, especially on the kidneys. Sir Francis Milman first taught the impropriety of this practice, which is now generally abandoned: at least so long as the flow of urine is increased in proportion to the drink taken, it is considered proper to indulge the patient with it. Another evacuation, which it is very desirable to promote in anasarca, is that by the skin, but this is with difficulty accomplished: nauseating emetics are the most powerful means, but transient in their effect, and their frequent use cannot be borne. If a gentle diaphoresis can be excited, it is as much as we could expect; and perhaps on the whole most beneficial to the patient. For this purpose the compound powder of ipecacuanha, saline substances, and antimonials in small doses, assisted by tepid drink, and warmth applied to the surface, may be had recourse to. Sometimes much relief is obtained by promoting perspiration locally by means of the vapour-bath. Mercury has been much employed in dropsy, and certainly appears often materially to promote the operation of other evacuants, particularly squill and digitalis; but its chief utility is where there are obstructions of the viscera, especially the liver, of which, however, ascites is usually the first result: its power of increasing absorption hardly appears, unless it is carried so far as to affect the mouth, when it is apt to weaken the system so much as greatly to limit its use. The other indication of invigorating the constitution, and particularly the exhalant arteries, may be accomplished by tonic medicines, as the several vegetable bitters, chalybeates in those who are remarkably pale, and, if there be a languid circulation, stimulants may be joined with them: a similar modification will be proper in the diet, which should be always as nutritious as the patient can well digest; directing also in torpid habits pungent articles, as garlic, onions, mustard, horseradish, &c. to be freely taken, which will be farther useful by promoting the urine. Rhenish wine, or punch made with hollands and supertartrate of potassa, may be allowed for the drink. Regular exercise, such as the patient can bear, (the limbs being properly supported, especially by a well-contrived laced stocking,) ought to be enjoined, or diligent friction of the skin, particularly of the affected parts, employed when the tumefaction is usually least, namely, in the morning. The cold bath, duly regulated, may also, when the patient is convalescent, materially contribute to obviate a relapse.

ANASPA'SIS. (From *ava*, and *σπαω*, to draw together.) Hippocrates uses this word to signify a contraction of the stomach.

ANA'SSYTOS. (From *ava*, upwards, and *σευομαι*, to agitate.) *Anassytus*. Driven forcibly upwards. Hippocrates applies this epithet to air rushing violently upwards, as in hysteric fits.

ANASTA'LTICA. (From *αναϛελλω*, to contract.) Styptic or refrigerating medicines.

ANA'STASIS. (From *αναϛημι*, to cause to rise.) 1. A recovery from sickness; a restoration of health.

2. It likewise signifies a migration of humours, when expelled from one place and obliged to remove to another.—*Hippocrates*.

ANASTOMO'SIS. (From *ava*, through, and *ϛομα*, a mouth.) The communication of vessels with one another.

ANASTOMO'TIC. (*Anastomoticus*; from *ava*, through, and *ϛομα*, the mouth.) That which opens the pores and mouths of the vessels, as cathartics, diuretics, deobstruents and sudorifics.

ANATASE. A mineral found only in Dauphiny and Norway.

ANA'TES. (From *nates*, the buttocks.) A disease of the anus. *Festus*, &c.

ANATO'MIA. See *Anatomy*.

ANA'TOMY. (*Ανατομια*, or *ανατομη*. *Anatomia*, *æ*. f. and *Anatome*, *es*; from *ava*, and *τεμνω*, to cut up.) *Androtomy*. The dissection or dividing of organised substances to expose the structure, situation, and uses of parts. Anatomy is divided into that of animals strictly so called, also denominated *zootomy*, and that of vegetables or *phytotomy*.

The anatomy of brute animals and vegetables is comprised under the term comparative anatomy, because their dissections was instituted to illustrate or compare by analogy their structure and functions with those of the human body.

ANATOMY COMPARATIVE. Zootomy. The dissection of brutes, fishes, polypi, plants, &c. to illustrate, or compare them with the structure and functions of the human body.

ANATRE'SIS. (From *ava*, and *τιτραω*, to perforate.) A perforation like that which is made upon the skull by trepanning.

ANATRI'BE. (From *ανατριβω*, to rub.) Friction all over the body.

ANATRI'PSIS. Friction all over the body.—*Moschion de Morb. Mulieb.* and *Galen.*

ANA'TRIS. Mercury.—*Ruland.*

ANA'TRON. (Arabian.) The name of a lake in Egypt, where it was produced. See *Soda.*

ANA'TROPE. (From *ανατρεπω*, to subvert.) *Anatrophe*; *Anatropha*. A relaxation, or subversion of the stomach, with loss of appetite and nausea. Vomiting; indigestion.—*Galen.*

ANA'TRUM. Soda.

ANAU'DIA. (From *a*, priv. and *αυδη*, the speech.) Dumbness; privation of voice; catalepsy.—*Hippocrates.*

ANA'XYRIS. (From *αναξυρις*, the sole.) The herb sorrel; so called because its leaf is shaped like the sole of the shoe.

ANCEPS. (*Anceps, ipitis.* adjective.) Two-edged; that is compressed, having the edges sharp like a two-edged sword; applied to stems and leaves of plants, as in the *Sisyrinchium striatum*, *Iris graminea* and leaves of the *Typha latifolia.*

A'NCHA. (Arabian, to press upon, as being the support of the body.) The thigh.—*Avicenna*, *Forestius*, &c.

A'NCHILOPS. (From *αγχι*, near, and *ωψ*, the eye.) A disease in the inward corner of the eye. See *Ægilops*.

ANCHORA'LIS. (From *αγκων*, the elbow.) The projecting part of the elbow on which we lean, called generally the olecranon. See *Ulna.*

ANCHORALIS PROCESSUS. The olecranon, a process of the ulna.

ANCHOVY. See *Clupea encrasicolus.*

Anchovy Pear. See *Grias cauliflora.*

ANCHU'SA. (*Anchusa, æ.* f.; from *αγχειν*, to strangle: from its supposed constringent quality; or, as others say, because it strangles serpents.) 1. The name of a genus of plants in the Linnæan system. Class, *Pentandria*; Order, *Monogynia.*

2. The name in some pharmacopœias for the alkanet root and bugloss. See *Anchusa officinalis*, and *Anchusa tincturia.*

ANCHUSA OFFICINALIS. The officinal bugloss. In some pharmacopœias it is called *Buglossa*; *Buglossum angustifolium majus*; *Buglossum vulgare majus*; *Buglossum sylvestre*; *Buglossum sativum*. *Anchusa—foliis lanceolatis* *strigosis, spicis secundis imbricatis, calycibus quinque partitis*, of Linnæus: it was formerly esteemed as a cordial in melancholic and hypochondriacal diseases. It is seldom used in modern practice, and then only as an aperient and refrigerant.

ANCHUSA TINCTORIA. The systematic name for the anchusa or alkanna of the pharmacopœias. This plant grows wild in France, but is cultivated in our gardens. The root is externally of a deep purple colour. To oil, wax, turpentine, and alcohol, it imparts a beautiful deep red colour, for which purpose it is used. Its medicinal properties are scarcely perceptible.

A′NCHYLE. See *Ancyle.*

ANCHYLOMERI′SMA. (From αγχυλομαι, to bend.) Sagar uses this term to express a concretion, or growing together of the soft parts.

ANCHYLO′SIS. (From αγχυλομαι, to bend.) A stiff joint. It is divided into the *true* and *spurious*, according as the motion is entirely or but partly lost. This state may arise from various causes, as tumefaction of the ends of the bones, caries, fracture, dislocation, &c. also dropsy of the joint, fleshy excrescences, aneurisms, and other tumours. It may also be owing to the morbid contraction of the flexor muscles, induced by the limb being long kept in a particular position, as a relief to pain, after burns, mechanical injuries, &c. The rickets, white swellings, gout, rheumatism, palsy, from lead particularly, and some other disorders, often lay the foundation of anchylosis: and the joints are very apt to become stiff in advanced life. Where the joint is perfectly immoveable, little can be done for the patient; but in the spurious form of the complaint, we must first endeavour to remove any cause mechanically obstructing the motion of the joint, and then to get rid of the morbid contraction of the muscles. If inflammation exist, this must be first subdued by proper means. Where extraneous matters have been deposited, the absorbents must be excited to remove them: and where the parts are preternaturally rigid, emollient applications will be serviceable. Fomentations, gentle friction of the joint and of the muscles, which appear rigid, with the camphor linament, &c. continued for half an hour or more two or three times a day; and frequent attempts to move the joint to a greater extent, especially by the patient exerting the proper muscles, not with violence, but steadily for some time, are the most successful means: but no rapid improvement is to be expected in general. Sometimes, in obstinate cases, rubbing the part with warm brine occasionally, or applying stimulant plasters of ammoniacum, &c. may expedite the cure; and in some instances, particularly as following rheumatism, pumping cold water on the part every morning has proved remarkably beneficial. Where there is a great tendency to contraction of the muscles, it will be useful to obviate this by some mechanical contrivance. It is proper to bear in mind, where, from the nature of the case, complete anchylosis cannot be prevented, that the patient may be much less inconvenienced by its being made to occur in a particular position; that is in the upper extremities generally a bent, but in the hip or knee an extended one.

A′NCI. A term formerly applied to those who have a distorted elbow.

A′NCINAR. Borax.

ANCIPITIUS. (From *Anceps.*) Two-edged: applied to a leaf which is compressed and sharp at both edges as that of the *Typha latifolia.*

ANCIROME′LE. See *Ancylomele.*

A′NCON. (From αγκαζομαι, to embrace; απο του αγκεισθαι στερω οςεω το οςεον: because the bones meeting and there uniting, are folded one into another.) The elbow.

ANCONE′US. (From αγκων, the elbow.) A small triangular muscle, situated on the back part of the elbow. *Anconeus minor* of Winslow; *Anconeus vel cubitalis Riolani* of Douglas. It arises from the ridge, and from the external condyle of the humerus, by a thick, strong, and short tendon: from this it becomes fleshy, and, after running about three inches obliquely backwards, it is inserted by its oblique fleshy fibres into the back part or ridge of the ulna. Its use is to extend the fore-arm.

ANCONEUS EXTERNUS. See *Triceps extensor cubiti.*

ANCONEUS INTERNUS. See *Triceps extensor cubiti.*

ANCONEUS MAJOR. See *Triceps extensor cubiti.*

ANCONEUS MINOR. See *Anconeus.*

ANCONOID. (*Anconoideus;* from αγκων, the elbow.) Belonging to the elbow.

ANCONOID PROCESS. See *Ulna.*

A′NCTER. (Αγκτηρ, a bond, or button.) A fibula, or button, by which the lips of wounds are held together.—*Gorræus.*

ANCTERIA′SMUS. (From αγκτηρ, a button.) The operation of closing the lips of wounds together by loops, or buttons.—*Galen.*

ANCU′BITUS. A disease of the eyes with a sensation as if sand were in them.—*Joh. Anglic. Ros. Ang.*

A′NCYLE. (From αγκυλος, crooked.) *Anchyle.* A species of contraction, called a stiff joint.—*Galen.*

ANCYLION. See *Ancyloglossum.*

ANCYLOBLE′PHARON. (*Ancyloblepharum, i. n.*; from αγκυλη, a hook, and βλεφαρον, an eyelid.) A disease of the eye, by which the eyelids are closed together.—*Aëtius.*

ANCYLOGLO′SSUM. (*Ancyloglossum, i. n.*; from αγκυλη, a hook, and γλωσσα, the tongue.) *Ancylion* of Ægineta. Tongue-tied. A contraction of the frænulum of the tongue.

ANCYLOME′LE. (From αγκυλος, crooked, and μηλη, a probe.) *Ancyromele; Anciromele.* A crooked probe, or a probe with a hook, with which surgeons searched wounds.—*Galen,* &c.

ANCYLO′SIS. See *Anchylosis.*

ANCYLO′TOMUS. (From αγκυλη, a hook, and τεμνω, to cut.) A crooked chirurgical knife, or bistoury. A knife for loosening the tongue, not now used.

A′NCYRA. (Αγκυρα, an anchor.) A chirurgical hook. Epicharmus uses this word for the membrum virile, according to Gorræus.

ANCYROI′DES. (*Ancyroides processus;* from αγκυρα, an anchor, and ειδος, a likeness.) A process of the scapula was so called, from its likeness to the beak of an anchor. The coracoid process of the scapula. See *Scapula.*

ANCYROME′LE. See *Ancylomele.*

ANDALUSITE. A massive mineral, of a flesh, and sometimes rose-red, colour, belonging to primitive countries, and first found in Andalusia in Spain.

Anderson's pills. These consist of Barbadoes aloes, with a proportion of jalap, and oil of aniseed.

ANDI′RA. A tree of Brazil, the fruit of which is bitter and astringent, and used as a vermifuge.

ANDRANATO′MIA. (From ανηρ, a man, and τεμνω, to cut.) *Andranatome.* The dissection of the human body, particularly of the male. —*M. Aur. Severinus, Zootome Democrit.*

ANDRAPODOCAPE′LUS. (From ἀνδροποδον, a

slave, and καπηλος, a dealer.) A crimp. Galen calls by this name the person whose office it was to anoint and slightly to wipe the body, to cleanse the skin from foulness.

ANDREOLITE. A species of crop-stone.

ANDROCŒTE'SIS. (From ανηρ, a man, and κοιτεω, to cohabit with.) 1. The venereal act.

2. The infamous act of sodomy.—*Moschion*, &c.

ANDRO'GYNUS. (From ανηρ, a man, and γυνη, a woman.) 1. An hermaphrodite.

2. An effeminate person.—*Hippocrates*.

3. A plant is said to be androgenous, which produces both male and female flowers from the same root, as the walnut, beech, horn-beam, nettle, &c.

ANDRO'MACHUS, of *Crete*, was physician to the Emperor Nero. He invented a composition, supposed to be an antidote against poison, called after him, *Theriaca Andromachi*, which he dedicated to that Emperor in a copy of Greek verses still preserved. This complicated preparation long retained its reputation, but is now deservedly abandoned.

ANDRO'NION. *Andronium*. A kind of plaster used by Ægineta for carbuncles, invented by Andron.

ANDROPO'GON. (From ανηρ, a man, and πωγων, a beard.) The name of a genus of plants in the Linnæan system. Class, *Polygamia*: Order, *Monœcia*.

ANDROPOGON NARDUS. The systematic name of Indian nard or spikenard. *Spica nardi*; *Spica Indica*. The root of this plant is an ingredient in the mithridate and theriaca; it is moderately warm and pungent, accompanied with a flavour not disagreeable. It is said to be used by the Orientals as a spice.

ANDROPOGON SCHÆNANTHUS. The systematic name of the Camel-hay, or Sweet-rush. *Juncus odoratus*; *Fœnum camelorum*; *Juncus aromaticus*. The dried plant is imported into this country from Turkey and Arabia. It has an agreeable smell, and a warm, bitterish, not unpleasant taste. It was formerly employed as a stomachic and deobstruent.

ANDRO'TOMIA. *Androtome*. Human dissection, particularly of the male.

ANDRY, NICHOLAS, a physician, born at Lyons in 1658. He was made professor of medicine at Paris in 1701, and lived to the age of 84. Besides a Treatise on Worms, and other minor publications, and contributions in the Medical and Philosophical Journals, he was author of a work, still esteemed, called "Orthopedie," or the art of preventing and removing deformities in children; which he proposed to effect by regimen, exercise, and various mechanical contrivances.

ANE'BIUM. (From αναβαινω, to ascend.) The herb alkanet, so called from its quick growth. See *Anchusa*.

ANEILE'SIS. (From ανειλεω, to roll up.) *Aneilema*. An involution of the guts, such as is caused by flatulence and gripes.—*Hippocrates*.

ANE'MIA. (From ανεμος, wind.) Flatulence.

ANE'MONE. (From ανεμος, wind; so named, because it does not open its flowers till blown upon by the wind.) The name of a genus of plants in the Linnæan system. Class, *Polyandria*; Order, *Polygynia*. The wind flower.

ANEMONE HEPATICA. The systematic name for the *hepatica nobilis* of the pharmacopœias. *Herba trinitatis*. Hepatica, or herb trinity. This plant possesses mildly adstringent and corroborant virtues, with which intentions infusions of it have been drunk as tea, or the powder of the dry leaves given, to the quantity of half a spoonful at a time.

ANEMONE NEMOROSA. The systematic name of the *ranunculus albus* of the pharmacopœias. The bruised leaves and flowers are said to cure tinea capitis applied to the part. The inhabitants of Kamskatka, it is believed, poison their arrows with the root of this plant.

ANEMONE PRATENSIS. The systematic name for the *Pulsatilla nigricans* of the pharmacopœias. This plant, *Anemone—pedunculo involucrato, petalis apice reflexis, foliis bipinnatis*, of Linnæus, has been received into the Edinburgh pharmacopœia upon the authority of Baron Stoerck, who recommended it as an effectual remedy for most of the chronic diseases affecting the eye, particularly amaurosis, cataract, and opacity of the cornea, proceeding from various causes. He likewise found it of great service in venereal nodes, nocturnal pains, ulcers, caries, indurated glands, suppressed menses, serpiginous eruptions, melancholy and palsy. The plant, in its recent state, has scarcely any smell; but its taste is extremely acrid, and, when chewed, it corrodes the tongue and fauces.

ANENCE'PHALUS. (From α, priv. and εγκεφαλος, the brain.) A monster without brains. Foolish.—*Galen de Hippocrate*.

A'NEOS. A loss of voice and reason.

ANEPITHY'MIA. (From α, priv. and επιθυμια, desire.) Loss of appetite.

A'NERIC. *Anerit*. Sulphur vivum.

A'NESIS. (From ανιημι, to relax.) A remission, or relaxation, of a disease, or symptom. *Aëtius*, &c.

ANE'SUM. See *Anisum*.

ANE'THUM. (*Anethum*, *i*. n. Ανηθον; from ανευ, afar, and θεω, to run: so called because its roots run out a great way.)

1. The name of a genus of plants in the Linnæan system. Class, *Pentandria*; Order, *Digynia*.

2. The pharmacopœial name of the common dill. See *Anethum graveolens*.

ANETHUM FŒNICULUM. The systematic name for the *fœniculum* of the shops. Sweet fennel, *Anethum—fructibus ovatis* of Linnæus. The seeds and roots of this indigenous plant are directed by the colleges of London and Edinburgh. The seeds have an aromatic smell, and a warm sweetish taste, and contain a large proportion of essential oil. They are stomachic and carminative. The root has a sweet taste, but very little aromatic warmth, and is said to be pectoral and diuretic.

ANETHUM GRAVEOLENS. The systematic name for the *Anethum* of the shops. *Anethum—fructibus compressis*, of Linnæus.—*Dill*. *Anet*. This plant is a native of Spain, but cultivated in several parts of England. The seeds are directed for use by the London and Edinburgh Pharmacopœias: they have a moderately warm, pungent taste, and an aromatic, but sickly smell. There is an essential oil, and a distilled water, prepared from them, which are given in flatulent colics and dyspepsia. They are also said to promote the secretion of milk.

ANE'TICA. (*Aneticus*; from ανιημαι, to relax.) Medicines which assuage pain, according to Andr. Tiraquell.

ANETUS. (From ανιημι, *remitto*.) A name given by Good, in his Study of Medicine, to a genus of diseases which embraces intermittent fevers. See *Nosology*.

ANEURI'SMA. (*Aneurisma*, *matis*. neut.

Ανευρυσμα; from *ανευρυνω*, to dilate.) An aneurism; a preternatural tumour formed by the dilatation of an artery. A genus of disease ranked by Cullen in the class *Locales*, and order *Tumores.* There are three species of aneurism: 1. The *true aneurism, aneurisma verum*, which is known by the presence of a pulsating tumour. The artery either seems only enlarged at a small part of its tract, and the tumour has a determinate border, or it seems dilated for a considerable length, in which circumstance the swelling is oblong, and loses itself so gradually in the surrounding parts, that its margin cannot be exactly ascertained. The first, which is the most common, is termed *circumscribed true aneurism;* the last, the *diffused true aneurism.* The symptoms of the circumscribed true aneurism, take place as follows: the first thing the patient perceives is an extraordinary throbbing in some particular situation, and, on paying a little more attention, he discovers there a small pulsating tumour, which entirely disappears when compressed, but returns again as soon as the pressure is removed. It is commonly unattended with pain or change in the colour of the skin. When once the tumour has originated, it continually grows larger, and at length attains a very considerable size. In proportion as it becomes larger, its pulsation becomes weaker, and, indeed, it is almost quite lost, when the disease has acquired much magnitude. The diminution of the pulsation has been ascribed to the coats of the artery, losing their dilatable and elastic quality, in proportion as they are distended and indurated; and, consequently, the aneurismal sac being no longer capable of an alternate diastole and systole from the action of the heart. The fact is also imputed to the coagulated blood, deposited on the inner surface of the sac, particularly in large aneurisms, in which some of the blood is always interrupted in its motion. In true aneurisms, however, the blood does not coagulate so soon, nor so often, as in false ones. Whenever such coagulated blood lodges in the sac, pressure can only produce a partial disappearance of the swelling. In proportion as the aneurismal sac grows larger, the communication into the artery beyond the tumour is lessened. Hence, in this state, the pulse below the swelling becomes weak and small, and the limb frequently cold and œdematous. On dissection, the lower continuation of the artery is found preternaturally small, and contracted. The pressure of the tumour on the adjacent parts also produces a variety of symptoms, ulcerations, caries, &c. Sometimes an accidental contusion, or concussion, may detach a piece of coagulum from the inner surface of the cyst, and the circulation through the sac be obstructed by it. The coagulum may possibly be impelled quite into the artery below, so as to induce important changes. The danger of an aneurism arrives when it is on the point of bursting, by which occurrence the patient usually bleeds to death; and this sometimes happens in a few seconds. The fatal event may generally be foreseen, as the part about to give way becomes particularly tense, elevated, thin, soft, and of a dark purple colour. 2. The *false* or *spurious aneurism, aneurisma spurium,* is always owing to an aperture in the artery, from which the blood gushes into the cellular substance. It may arise from an artery being lacerated in violent exertions: but the most common occasional cause is a wound. This is particularly apt to occur at the bend of the arm, where the artery is exposed to be injured in attempting to bleed. When this happens, as soon as the puncture has been made, the blood gushes out with unusual force, of a bright scarlet colour and in an irregular stream, corresponding to the pulsation of the artery. It flows out, however, in an even and less rapid stream when pressure is applied higher up than the wound. These last are the most decisive marks of the artery being opened; for blood often flows from a vein with great rapidity, and in a broken current, when the vessel is very turgid and situated immediately over the artery, which imparts its motion to it. The surgeon endeavours precipitately to stop the hæmorrhage by pressure; and he commonly occasions a *diffused false aneurism.* The external wound in the skin is closed, so that the blood cannot escape from it; but insinuates itself into the cellular substance. The swelling thus produced is uneven, often knotty, and extends upwards and downwards, along the tract of the vessel. The skin is also usually of a dark purple colour. Its size increases as long as the internal hæmorrhage continues, and, if this should proceed above a certain pitch, mortification of the limb ensues. 3. The *varicose aneurism, aneurisma varicosum:* this was first described by Dr. W. Hunter. It happens when the brachial artery is punctured in opening a vein: the blood then rushes into the vein, which becomes varicose. Aneurisms may happen in any part of the body, except the latter species, which can only take place where a vein runs over an artery. When an artery has been punctured, the tourniquet should be applied, so as to stop the flow of blood by compressing the vessel above; then the most likely plan of obviating the production of spurious aneurism appears to be applying a firm compress immediately over the wound, and securing it by a bandage, or in any other way, so as effectually to close the orifice, yet not prevent the circulation through other vessels: afterwards keeping the limb as quiet as possible, enjoining the antiphlogistic regimen, and examining daily that no extravasation has happened, which would require the compress being fixed more securely, previously applying the tourniquet, and pressing the effused blood as much as possible into the vessel. If there should be much coldness or swelling of the limb below, it will be proper to rub it frequently with some spirituous or other stimulant embrocation. It is only by trial that it can be certainly determined when the wound is closed; but always better not to discontinue the pressure prematurely. The same plan may answer, when the disease has already come on, if the blood can be entirely, or even mostly, pressed into the artery again; at any rate, by determining the circulation on collateral branches, it will give greater chance of success to a subsequent operation. There is another mode, stated to have sometimes succeeded, even when there was much coagulated blood; namely, making strong pressure over the whole limb, by a bandage applied uniformly, and moistened to make it sit closer, as well as to obviate inflammation; but this does not appear so good a plan, at least in slighter cases. If however the tumour be very large, and threatens to burst, or continues spreading, the operation should not be delayed. The tourniquet being applied, a free incision is to be made into the tumour, the extravasated blood removed, and the artery tied both above and below the wound, as near to it as may be safe; and if any branch be given off between, this must be also secured. It is better not to make the ligatures tighter, than may be necessary to stop the flow of blood; and to avoid including any nerve if possible. Sometimes, where extensive suppuration or caries has occurred, or gangrene is to be apprehended, amputation will be necessary: but this must not be prematurely resolved upon, for often after several weeks the pulse has returned in the limb below. In the true aneurism, when small and recent, cold and astringent applications are sometimes useful; or making pressure on the tumour, or on the artery above, may succeed; otherwise an operation becomes necessary to save the patient's life; though unfortunately it oftener fails in this than in the spurious kind; gangrene ensuing, or hæmorrhage; this chiefly arises from the arteries being often extensively diseased, so that they are more likely to give way, and there is less vital power in the limb. A great improvement has been made in the mode of operating in these cases by Mr. John Hunter, and other modern surgeons, namely, instead of proceeding as already explained in the spurious aneurism, securing the artery some way above, and leaving the rest in a great measure to the powers of nature. It has been now proved by many instances, that when the current of the blood is thus interrupted, the tumour will cease to enlarge, and often be considerably diminished by absorption. There is reason for believing too, that the cures effected spontaneously, or by pressure, have been usually owing to the trunk above being obliterated. There are many obvious advantages in this mode of proceeding; it is more easy, sooner performed, and disorders the system less, particularly as you avoid having a large unhealthy sore to be healed; besides there is less probability of the vessel being diseased at some distance from the tumour. In the popliteal aneurism, for example, the artery may be secured rather below the middle of the thigh, where it is easily come at. The tourniquet therefore being applied, and the vessel exposed, a strong ligature is to be passed round it; or, which is perhaps preferable, two ligatures a little distant, subsequently cutting through the artery between them, when the two portions contract among the surrounding flesh. It is proper to avoid including the nerve or vein, but not unnecessarily detach the vessel from its attachments. For greater security one end of each ligature, after being tied, may be passed through the intercepted portion of artery, that they may not be forced off. Then the wound is to be closed by adhesive plaster, merely leaving the ends of the ligatures hanging out, which will after some time come away. However it must be remembered that hæmorrhage is liable to occur, when this happens, even three or four weeks after the operation; so that proper precautions are required, to check it as soon as possible; likewise the system should be lowered previously, and kept so during the cure. When a true aneurism changes into the spurious form, which is known by the tumour spreading, becoming harder, and with a less distinct pulsation, the operation becomes immediately necessary. When an aneurism is out of the reach of an operation, life may be prolonged by occasional bleeding, a spare diet, &c.; and when the tumour becomes apparent externally, carefully guarding it from injury. In the varicose aneurism an operation will be very seldom if ever required, the growth of the tumour being limited.

ANEURISMA SPURIUM. See *Aneurisma.*

ANEURISMA VARICOSUM. See *Aneurisma.*

ANEURISMA VERUM. See *Aneurisma.*

ANE'XIS. (From *ανεχω*, to project.) A swelling, or protuberance.

ANGEIOLO'GY. (*Angeiologia, æ.* f.; from *αγγειον*, a vessel, and *λογος*, a discourse.) A dissertation, or reasoning, upon the vessels of the body.

ANGEIOTI'SMUS. (From *αγγειον*, a vessel, and *τεμνω*, to cut.) An angeiotomist, or skilful dissector of the vessels.

ANGEIO'TOMY. (*Angeiotomia*; from *αγγειον*, a vessel, and *τεμνω*, to cut.) The dissection of the blood-vessels of an animal body; also the opening of a vein, or an artery.

ANGE'LICA. (So called from its supposed angelic virtues.) 1. The name of a genus of plants in the Linnæan system. Class, *Pentandria*; Order, *Digynia.* Angelica.

2. The pharmacopœial name of the garden angelica. See *Angelica archangelica.*

ANGELICA ARCHANGELICA. The systematic name for the *angelica* of the shops. *Milzadella Angelica—foliorum impari lobato* of Linnæus. A plant, a native of Lapland, but cultivated in our gardens. The roots of angelica have a fragrant, agreeable smell, and a bitterish, pungent taste. The stalk, leaves, and seeds, which are also directed in the pharmacopœias, possess the same qualities, though in an inferior degree. Their virtues are aromatic and carminative. A sweetmeat is made, by the confectioners, of this root, which is extremely agreeable to the stomach, and is surpassed only by that of ginger.

Angelica, garden. See *Angelica archangelica.*

ANGELICA PILULA. Anderson's Scots pills.

ANGELICA SATIVA. See *Angelica sylvestris.*

ANGELICA SYLVESTRIS. *Angelica sativa.* Wild angelica. *Angelica—foliis æqualibus ovato-lanceolatis serratis*, of Linnæus. This species of angelica possesses similar properties to the garden species, but in a much inferior degree. It is only used when the latter cannot be obtained. The seeds, powdered and put in the hair, kill lice.

Angelica, wild. See *Angelica sylvestris.*

ANGELICUS. (From *angelus*, an angel.) Some plants, &c. are so called, from their supposed superior virtues.

ANGELICUS PULVIS. Submuriate of mercury.

ANGELI'NA. *Angelina zanoni acostæ.* A tree of vast size, sometimes above sixteen feet thick, growing in rocky and sandy places in Malabar in the East Indies. It bears ripe fruit in December. The dried leaves heated are said to alleviate pains and stiffness of the joints, and dismiss swelling of the testes caused by external violence; and are also said to be useful in the cure of venereal complaints.

ANGELINÆ CORTEX. The name of the tree from which the *Cortex angelinæ* is procured. It is a native of Grenada. This bark has been recommended as an anthelmintic for children.

ANGELOCA'COS. The purging Indian plum. See *Myrobalanus.*

A'NGI. (From *angor*, anguish; because of their pain.) Buboes in the groin.—*Fallopius de Morbo Gallico.*

ANGIGLO'SSUS. (From *αγκυλη*, a hook, and *γλωσσα*, the tongue.) A person who stammers.

ANGI'NA. (*Angina, æ.* f.; from *αγχω*, to strangle; because it is often attended with a sense of strangulation.) A sore throat. See *Cynanche.*

ANGINA LINI. A name used by some of the later Greek writers to express what the more ancient writers of this nation called *linozostres*, and the Latins *epilinum*: which is the *cuscuta* or dodder, growing on the *linum* or flax, as that on the thyme was called *epithymum.* See *Cuscuta.*

ANGINA MALIGNA. Malignant or putrid sore throat. See *Cynanche maligna.*

ANGINA PAROTIDEA. The mumps. See *Cynanche parotidea.*

ANGINA PECTORIS. *Syncope anginosa* of Dr. Parry. An acute constrictory pain at the lower end of the sternum, inclining rather to the left side, and extending up into the left arm, accompanied with great anxiety. Violent palpitations of the heart, laborious breathings, and a sense of suffocation, are the characteristic symptoms of this disease.—It is found to attack men much more frequently than women, particularly those who have short necks, who are inclinable to corpulency, and who, at the same time, lead an inactive and sedentary life. Although it is sometimes met with in persons under the age of twenty, still it more frequently occurs in those who are between forty and fifty. In slight cases, and in the first stage of the disorder, the fit comes on by going up-hill, up-stairs, or by walking at a quick pace after a hearty meal; but as the disease advances, or becomes more violent, the paroxysms are apt to be excited by certain passions of the mind; by slow walking, by riding on horseback, or in a carriage; or by sneezing, coughing, speaking, or straining at stool. In some cases, they attack the patient from two to four in the morning, or whilst sitting or standing, without any previous exertion or obvious cause. On a sudden, he is seized with an acute pain in the breast, or rather at the extremity of the sternum, inclining to the left side, and extending up into the arm, as far as the insertion of the deltoid muscle, accompanied by a sense of suffocation, great anxiety, and an idea that its continuance, or increase, would certainly be fatal. In the first stage of the disease, the uneasy sensation at the end of the sternum, with the other unpleasant symptoms, which seemed to threaten a suspension of life by a perseverance in exertion, usually go off upon the person's standing still, or turning from the wind; but, in a more advanced stage, they do not so readily recede, and the paroxysms are much more violent. During the fit, the pulse sinks, in a greater or less degree, and becomes irregular; the face and extremities are pale, and bathed in a cold sweat, and, for a while, the patient is perhaps deprived of the powers of sense and voluntary motion. The disease having recurred more or less frequently during the space of some years, a violent attack at last puts a sudden period to his existence. Angina pectoris is attended with a considerable degree of danger; and it usually happens that the person is carried off suddenly. It mostly depends upon an ossification of the coronary arteries, and then we can never expect to effect a radical cure. During the paroxysms, considerable relief is to be obtained from fomentations, and administering powerful antispasmodics, such as opium and æther combined together. The application of a blister to the breast is likewise attended sometimes with a good effect. As the painful sensation at the extremity of the sternum often admits of a temporary relief, from an evacuation of wind by the mouth, it may be proper to give frequent doses of carminatives, such as peppermint, carraway, or cinnamon water. Where these fail in the desired effect, a few drops of ol. anisi, on a little sugar, may be substituted.

With the view of preventing the recurrence of the disorder, the patient should carefully guard against passion, or other emotions of the mind: he should use a light, generous diet, avoiding every thing of a heating nature; and he should take care never to overload the stomach, or to use any kind of exercise immediately after eating. Besides these precautions, he should endeavour to counteract obesity, which has been considered as a predisposing cause; and this is to be effected most safely by a vegetable diet, moderate exercise at proper times, early rising, and keeping the body perfectly open. It has been observed that angina pectoris is a disease always attended with considerable danger, and, in most instances, has proved fatal under every mode of treatment. We are given, however, to understand, by Dr. Macbride, that of late, several cases of it have been treated with great success, and the disease radically removed, by inserting a large issue in each thigh. These, therefore, should never be neglected. In one case, with a view of correcting, or draining off the irritating fluid, he ordered, instead of issues, a mixture of lime-water with a little of the spirituous juniperi comp., and an alterative proportion of Huxham's antimonial wine, together with a plain, light, perspirable diet. From this course the patient was soon apparently mended; but it was not until after the insertion of a large issue in each thigh, that he was restored to perfect health.

ANGINA TONSILLARIS. See *Cynanche tonsillaris.*

ANGINA TRACHEALIS. See *Cynanche trachealis.*

ANGIOCARPI. The name given by Persoon to a division of funguses which bear their seeds internally. They are either hard or membranous, tough and leathery.

ANGIOLO'GY. (*Angiologia;* from *εγγειον*, a vessel, and *λογος*, a discourse.) The doctrine of the vessels of the human body.

ANGIOSPERMIA. (From *αγγος*, a vessel, and *σπερμα*, a seed.) The name of an order of plants in the class *Didynamia* of the sexual system of Linnæus, the seeds of which are lodged in a pericarpium or seed vessel.

ANGIOSPERMÆ HERBÆ. Those plants, the seeds of which are inclosed in a covering or vessel.

A'NGLICUS. (From *Anglia*, England.) The sweating sickness, which was so endemic and fatal in England, was called Sudor Anglicanus. See *Sudor Anglicus.*

ANGO'LAM. A very tall tree of Malabar, possessing vermifuge powers.

ANGO'NE. (From *αγχω*, to strangle.) A nervous sort of quinsy, or hysteric suffocation, where the fauces are contracted and stopped up without inflammation.

A'NGOR. (*Angor, oris.* m.; from *Ango.*) Agony or intense bodily pain.—*Galen.*

A'NGOS. (Αγγος, a vessel.) A vessel. A collection of humours.

ANGULATUS. Angled. A term used to designate stem, leaves, petioles, &c. which prevent several acute angles in their circumference. There are several varieties of angular stems.

1. *Triangulatus*, three-angled; as in *Cactus triangularis.*

2. *Quadrangulatus*, four-angled; as in *Cactus tetragonus.*

3. *Quinqueangulatus*, five-angled; as in *Castus pentagonus.*

4. *Hexangulatus*, six-angled; as in *Catcus hexagonus.*

5. *Multiangulatus*, many-angled; as in *Cactus cereus.*

6. *Obtusangularis*, obtuse-angled; as in *Scrofularia nodosa.*

7. *Acutangulatus*, acute-angled; as in *Scrofularia aquatica.*

8. *Caulis triqueter*, three-sided, but with flat-sides; as in *Hedysarum triquetrum, Violamirabilis, Carex acuta.*

9. *Caulis tetraquetrus*, quadrangular with flat-sides; as in *Hypericum quadrangulare, Mentha officinales.*

For angular leaves, see *Leaf*, *Petiole*, &c.

ANGULOSUS. Angular.

ANGUSTU'RÆ CORTEX. A bark imported from Angustura. See *Cusparia*.

ANHELA'TION. (*Anhelatio*; from *anhelo*, to breath with difficulty.) *Anhelitus.* Shortness of breathing.

ANHYDRITE. Anhydrous gypsum. There are six varieties of this mineral sulphate of lime. 1. The compact. 2. The granular. 3. The fibrous. 4. The radiated. 5. The sparry or cube spar. 6. The siliciferous or vulpinite.

ANHYDROS. A name given by the ancient Greeks, to express one of those kinds of *Strychna* or night shades, which, when taken internally, caused madness.

ANHYDROUS. (From α, neg. and υδωρ, water.) Without water.

ANICE'TON. (From α, priv. and νικη, victory.) A name of a plaister invented by Crito, and so called because it was thought an infallible or invincible remedy for achores, or scald-head. It was composed of litharge, alum, and turpentine, and is described by Galen.

Anil. The name of the Indigo plant.

A'NIMA. A soul: whether rational, sensitive or vegetative. The word is pure Latin, formed of ανεμος, breath. It is sometimes used by physicians to denote the principle of life in the body, in which sense Willis calls the blood *anima brutalis*. By chemists it was used figuratively for the volatile principle in bodies, whereby they were capable of being raised by the fire; and by the old writers on botany, materia medica, and pharmacy, it was frequently employed to denote its great efficacy: hence *anima hepates*, *aloes*, *rhabarbari*, &c.

ANIMA ALOES. Refined aloes.

ANIMA ARTICULORUM. A name of the Hermodactyles. See *Hermodactylus*.

ANIMA HEPATIS. Sal martis.

ANIMA PULMONUM. The soul of the lungs. A name given to saffron, on account of its use in asthmas.

ANIMA RHABARBARI. The best rhubarb.

ANIMA SATURNI. A preparation of lead.

ANIMA VENARIS. A preparation of copper.

ANIMAL. An organized body endowed with life and voluntary motion. The elements which enter into the composition of the bodies of animals are solid, liquid, gaseous, and inconfinable.

Solid Elements. Phosphorus, sulphur, carbon, iron, manganese, potassium, lime, soda, magnesia, silica, and alumina.

Liquid Elements. Muriatic acid; water, which in this case may be considered as an element, enters into the organization, and constitutes three-fourths of the bodies of animals.

Gaseous Elements. Oxygen, hydrogen, azote.

Inconfinable Elements. Caloric, light, electric and magnetic fluids.

These diverse elements, united with each other, three and three, four and four, &c. according to laws still unexplained, form what we name the proximate principles of animals.

Proximate Materials, or Principles. These are divided into azotised, and non-azotised.

The azotised principles are: albumen, fibrin, gelatin, mucus, cheese-curd principle, urea, uric acid, osmazome, colouring matter of the blood.

The non-azotised principles are: the acetic, benzoic, lactic, formic, oxalic, rosacic, acids; sugar of milk, sugar of diabetic urine, picromel, yellow colouring matter of bile, and of other liquids or solids which become yellow accidentally, the blistering principle of cantharides, spermaceti, biliary calculus, the odoriferous principles of ambergris, musk, castor, civet, &c. which are scarcely known, except for their faculty of acting on the organ of smell.

Animal fats are not immediate, simple, proximate principles. It is proved that human fat, that of the pig, of the sheep, &c. are principally formed by two fatty bodies, *stearin* and *elain*, which present very different characters that may be easily separated.

Neither is the butter of the cow a simple body; it contains acetic acid, a yellow colouring principle, an odorous principle, which is very manifest in fermented cheese.

We must not reckon among these substances, adipocire, a matter which is seen in bodies long buried in the earth: it is composed of *margarine*, of a fluid acid fat, of an orange colouring principle, and of a peculiar odorous substance. Nor must this substance be confounded with spermaceti, and the biliary calculus, which are themselves very different from each other. It does not contain a single principle analagous to them.

Organic Elements. The materials or principles above mentioned combine among themselves, and from their combination arise the organic elements, which are solid or liquid. The laws or forces that govern these combinations are entirely unknown.

Organic Solids. The solids have sometimes the form of canals, sometimes that of large or small plates, at other times they assume that of membranes. In man the total weight of solids is generally eight or nine times less than that of liquids. This proportion is nevertheless variable according to many circumstances.

The ancients believed that all the organic solids might be reduced by ultimate analysis to simple fibres, which they supposed were formed of earth, oil, and iron. Haller, who admitted this idea of the ancients, owns that this fibre is visible only to the eye of the mind. *Invisibilis est ea fibra sola; mentis acie distinguimus.* This is just the same as if he had said that it does not exist at all, which nobody at present doubts.

The ancients also admitted secondary fibres, which they supposed to be formed by particular modifications of the simple fibre. Thence, the nervous, muscular, parenchymatous, osseous fibre.

Chaussier has lately proposed to admit four sorts of fibres, which he calls *laminary*, *nerval*, *muscular*, and *albuginous*.

Science was nearly in this state when Pinel conceived the idea of distinguishing the organic solids, not by fibres, but by tissues or systems. Bichât applied it to all the solid parts of the bodies of animals: The classification of Bichât has been perfected by Dupuytren, and Richerand.

Classification of the Tissues.

1. Cellular		System
2. Vascular	Arterial. Venous. Lymphatic.	
3. Nervous	Cerebral. Ganglaic.	
4. Osseous		
5. Fibrous	Fibrous. Fibro-cartilaginous. Dermoid.	
6. Muscular	Voluntary. Involuntary.	
7. Erectile		
8. Mucous		
9. Serous		
10. Horny or Epidemic	Hairy. Epidermoid.	
11. Parenchymatous, Glandular.		

These systems, associated with each other and with the fluids, compose the *organs* or instruments of life. When many organs tend by their action towards a common end, we name them, collectively considered, an *apparatus.* The number of apparatus, and their disposition, constitute the differences of animals.—*Magendie.*

ANIMAL ACTIONS. *Actiones animales.* Those actions, or functions, are so termed, which are performed through the means of the mind. To this class belong the external and internal senses, the voluntary action of muscles, voice, speech, watching, and sleep. See *Action.*

Animal Heat. See *Heat Animal.*

Animal Œconomy. See *Œconomy animal.*

Animal Oil. *Oleum animale.* *Oleum animale Dippolii.* An empyreumatic oil, obtained from the bones of animals, recommended as an anodyne and antispasmodic.

A'NIME GUMMI. The substance which bears this name in the shops is a resin. See *Hymenæa courbaril.*

A'NIMI DELIQUIUM. (From *animus*, the mind, and *delinquo*, to leave.) Fainting. See *Syncope.*

A'NIMUS. This word is to be distinguished from *anima;* which generally expresses the faculty of reasoning, and *animus*, the being in which that faculty resides.

ANIN'GA. A root which grows in the Antilles islands, and is used by sugar-bakers for refining their sugar.

ANISCA'LPTOR. (From *anus*, the breech, and *scalpo*, to scratch.) The latissimus dorsi is so called, because it is the muscle chiefly instrumental in performing this office.—*Bartholin.*

ANISOTACHYS. (From *ανισος*, unequal, and *ταχυς*, quick.) A quick and unequal pulse.—*Gorræus.*

ANI'SUM. (From *α*, neg. and *ισος*, equal.) See *Pimpinella anisum.*

ANISUM SINENSE. See *Illicium anisatum.*

ANISUM STELLATUM. See *Illicium.*

ANISUM VULGARE. See *Pimpinella anisum.*

ANNEAL. We know too little of the arrangement of particles to determine what it is that constitutes or produces brittleness in any substance. In a considerable number of instances of bodies which are capable of undergoing ignition, it is found that sudden cooling renders them hard and brittle. This is a real inconvenience in glass, and also in steel, when this metallic substance is required to be soft and flexible. The inconveniences are avoided by cooling them very gradually, and this process is called annealing. Glass vessels, or other articles, are carried into an oven or apartment near the great furnace, called the leer, where they are permitted to cool, in a greater or less time, according to their thickness and bulk. The annealing of steel, or other metallic bodies, consists simply in heating them and suffering them to cool again, either upon the hearth of the furnace, or in any other situation where the heat is moderate, or at least the temperature is not very cold.

Annoto. See *Bixa orleana.*

ANNUAL. (*Annuus*, yearly.) A term applied in botany to plants and roots, which are produced from the seed, grow to their full extent, and die in one year or season, as *Papaver somniferum*, *Helianthus annuus*, *Hordeum Triticum*, &c.

ANNUE'NTES. (From *annuo*, to nod.) Some muscles of the head were formerly so called, because they perform the office of nodding, or bending the head downwards.—*Cowper*, &c.

ANNULAR. (*Annularis;* from *Annulus*, a ring, because it is ring-like, or the ring is worn on it, or it surrounds any thing like a ring; thus, annular bone, &c.

Annular bone. *Circulus osseus.* A ring-like bone, placed before the cavity of the tympanum in the fœtus.

Annular cartilage. See *Trachæa.*

ANNULA'RIS. *Annularis digitus.* The ring-finger. The one between the little and middle fingers.

ANNULARIS PROCESSUS. See *Pons varolii.*

A'NNULUS. (*Annulus*, *i*, m., a ring.) A ring. In botany applied to the slender membrane surrounding the stem of the fungi.

ANNULUS ABDOMINIS. The abdominal ring. An oblong separation of tendinous fibres, called an opening, in each groin, through which the spermatic chord in men, and the round ligament of the uteras in women, pass. It is through this part that the abdominal viscera fall in that species of hernia, which is called bubonocele. See *Obliquus externus abdominis.*

A'NO. (Ανω, upwards; in opposition to κατω, downwards.) Upwards.

ANOCATHA'RTIC. (From *ανω*, upwards, and *καθαιρω*, to purge.) Emetic, or that which purges upwards.

ANOCHEI'LON. (From *ανω*, upwards, and *χειλος*, the lip.) The upper lip.

ANO'DIA. (From *α*, neg. and *οδος*, the way.) Hippocrates uses this word for inaccuracy and irregularity in the description and treatment of a disease.

ANO'DYNA. See *Anodyne.*

ANODYNE. (*Anodynus;* from *α*, priv. and *ωδυνη*, pain.) Those medicines are termed *Anodynes*, which ease pain and procure sleep. They are divided into three sorts; paregorics, or such as assuage pain; hypnotics, or such as relieve by procuring sleep; and narcotics, or such as ease the patient by stupifying him.

ANO'DYNUM MARTIALE. Ferrum ammoniatum precipitated from water by potassa.

ANO'DYNUM MINERALE. Sal prunella.

ANOMALOUS. (From *α*, priv. and *νουος*, a law.) This term is often applied to those diseases, the symptoms of which do not appear with that regularity which is generally observed in diseases. A disease is also said to be anomalous, when the symptoms are so varied as not to bring it under the description of any known affection.

ANO'MPHALOS. (From *α*, priv. and *ομφαλος*, the navel.) *Anomphalus.* Without a navel.

ANO'NYMUS. (*Anonymus*, from *α*, priv. and *ονομα*, name.) Nameless; some eminences of the brain are called *columnæ anonymæ;* and it was formerly applied to one of the cricoid muscles.

ANO'RCHIDES. (From *α*, priv. and *ορχις*, the testicle.) Children are so termed which come into the world without testicles. This is a very common occurrence. The testicles of many male infants at the time of birth are within the abdomen. The time of their descent is very uncertain, and instances have occurred where they have not reached the scrotum at the age of ten or fifteen.

ANORE'XIA. (*Anorexia*, *æ*, f.; from *α*, priv. and *ορεξις*, appetite.) A want of appetite, without loathing of food. Cullen ranks this genus of disease in the class *Locales*, and order *Dysorexiæ.* He believes it to be generally symptomatic, but enumerates two species, viz. the *Anorexia humoralis*, and the *Anorexia atonica.* See *Dyspepsia.*

ANO'SMIA. (*Anosmia*, *æ*, f.; from *α*, neg. and *οζω*, to smell.) A loss of the sense of smelling.

This genus of disease is arranged by Cullen in the order *Locales*, and order *Dysæsthesiæ*. When it arises from a disease of the Schneiderian membrane, it is termed *Anosmia organica;* and when from no manifest cause, *Anosmia atonica*.

A'NSER. (*Anser, eris.* m.; a goose or gander.) The name of a genus of birds.

ANSER DOME'STICUS. The tame goose. The flesh of this bird is somewhat similar to that of the duck, and requires the assistance of spirituous and stimulating substances, to enable the stomach to digest it. Both are very improper for weak stomachs.

ANSERI'NA. (From *anser*, a goose; so called, because geese eat it.) See *Potentilla anserina*.

ANT. See *Formica rufa*.

Ant, acid of. See *Formic acid.*

ANTACID. (*Antacidus;* from αντι, against, and *acidus*, acid.) That which destroys acidity. The action of antacids in the human stomach, is purely chemical, as they merely combine with the acid present, and neutralize it. They are only palliatives, the generation of acidity being to be prevented by restoring the tone of the stomach and its vessels. Dyspepsia and diarrhœa are the diseases in which they are employed. The principal antacids in use are the alkalies; *e. g.* Liquoris potassæ, gutt. xv. or from 5 to 15 gr. of subcarbonate of potassa, or soda dissolved in water. The solution of soda called double soda-water, or that of potassa supersaturated with carbonic acid, is more frequently used, as being more pleasant. Ammonia has been recommended as preferable to every other antacid, from 10 to 20 drops of the liquor ammoniæ in a cupful of water. The liquor calcis, or lime water, is likewise used to correct acidity, two or three ounces being taken occasionally. Creta præparata alone, or with the addition of a small quantity of any aromatic—chelæ cancrorum præparatæ; magnesia also and its carbonate, are used for the same purpose.

ANTAGONIST. (*Antagonistus*, counteracting.) A term applied to those muscles which have opposite functions. Such are the flexor and extensor of any limb, the one of which contracts it, the other stretches it out; and also the abductors and adductors. Solitary muscles are those without any antagonist, as the heart, &c.

ANTA'LGIC. (*Antalgicus;* from αντι, against, and αλγος, pain.) That which relieves pain.

ANTA'LKALINE. (*Antalkalinus;* from αντι, against, and *alkali*, an alcali.) That which possesses the power of neutralizing alkalies. All the acids are of this class.

ANTAPHRODISI'AC. *Antaphrodisiacus;* from αντι, against, and Αφροδιτη, Venus. Antivenereal, or whatever extinguishes amorous desires.

ANTAPHRODI'TIC. The same.

ANTAPO'DOSIS. (From ανταποδιδωμι, to reciprocate.) A vicissitude, or return of the paroxysm of fevers.—*Hippocrates.* Called by Galen *epidosis*.

ANTARIS. Mercury.

ANTARTHRI'TIC. See *Antiarthritic.*

ANTASTHMA'TIC. See *Antiasthmatic.*

ANTATRO'PHIC. See *Antiatrophic.*

ANTECHE'SIS. (From αντεχομαι, to resist.) A violent stoppage in the bowels, which resists all efforts to remove it.—*Hippocrates.*

ANTELA'BIUM. (From *ante*, before, and *labium*, a lip.) The extremity of the lip.

ANTE'MBASIS. (From αντι, mutually, and εμβαινω, to enter.) A coalescence, or union of bone.—*Galen.*

ANTEME'TIC. See *Antiemetic.*

ANTENEA'SMUS. (From αντι, against, and τεινεσμος, implacable.) That species of madness in which the patient endeavours to destroy himself.

ANTEPHIA'LTIC. See *Antiphialtic.*

ANTEPILE'PTIC. See *Antiepileptic.*

ANTE'RIOR. Before. A term applied to what may be situated before another of the same kind, as a muscle, a projection, eminence, lobe, artery, &c.

ANTERIOR AURIS. *Musculus anterior auris.* One of the common muscles of the ear, situated before the external ear. It arises thin and membranous, near the posterior part of the *zygoma*, and is inserted into a small eminence on the back of the helix, opposite to the concha, which it draws a little forwards and upwards.

ANTERIOR INTERCOSTAL. *Nervus intercostalis anterior. Splanchnic nerve.* A branch of the great intercostal that is given off in the thorax.

ANTERIOR MALLEI. See *Laxator tympani.*

ANTHE'LIX. See *Antihelix.*

ANTHE'LMIA. (From αντι, against, and ελμινς, a worm; so called, because it was thought of great virtue in expelling worms.) See *Spigelia anthelmia* and *Marilandica.*

ANTHELMINTIC. (*Anthelminticus;* from αντι, against, and ελμινς, a worm.) Whatever procures the evacuation of worms from the stomach and intestines. The greater number of anthelmintics act mechanically, dislodging the worms, by the sharpness or roughness of their particles, or by their cathartic operation. Some seem to have no other qualities than those of powerful bitters by which they either prove noxious to these animals, or remove that debility of the digestive organs, by which the food is not properly assimilated, or the secreted fluids poured into the intestines are not properly prepared; circumstances from which it has been supposed the generation of worms may arise. The principal medicines belonging to this class, are, mercury, gamboge, Geoffræa inermis, tanacetum, polypodium filix mas, spigelia mariiandica, artemisia santonica, olea Europæa, stannum pulverisatum, ferri limaturæ, and dolichos pruriens; which see under their respective heads.

A'NTHEMIS. (*Anthemis, midis.* fœm.; from ανθεω, *floreo;* because it bears an abundance of flowers.) 1. The name of a genus of plants in the Linnæan system. Class, *Syngenesia;* Order, *Polygamia superflua.*

2. The name in the London Pharmacopœia for chamomile. See *Anthemis nobilis.*

ANTHEMIS COTULA. The systematic name for the plant called *Cotula fœtida; Chamæmelum fœtidum*, in the pharmacopœias. Mayweed. Stinking chamomile. This plant, *Anthemis:—receptaculis conicis paleis setaceis, seminibus nudis*, of Linnæus, has a very disagreeable smell; the leaves, a strong, acrid, bitterish taste; the flowers, however, are almost insipid. It is said to have been useful in hysterical affections, but is very seldom employed.

ANTHEMIS NOBILIS. The systematic name for the *Chamæmelum; Chamæmelum nobile; Chamomilla romana; Euanthemon* of Galen. *Anthemis* of the last London pharmacopœia. Common chamomile. *Anthemis—foliis pinnato-compositis linearibus acutis subvillosis*, of Linnæus. Both the leaves and flowers of this indigenous plant have a strong though not ungrateful smell, and a very bitter, nauseous taste: but the latter are the bitterer, and considerably more aromatic. They possess tonic and stomachic qualities, and are much employed to restore tone to the stomach and intestines, and as a pleasant and cheap bitter. They have been long successfully used for the cure of intermittents, as well as of fevers of the irregular nervous kind, accompanied with visceral obstructions. The flowers have been found useful in hysterical affections, flatulent or spasmodic colics, and dysentery; but, from their laxative quality, Dr. Cullen tells us they proved hurtful in diarrhœas. A simple infusion is frequently taken to excite vomiting, or for promoting the operation of emetics. Externally they are used in the *decoctum pro fomento*, and are an ingredient in the *decoctum malvæ compositum*.

ANTHEMIS PYRETHRUM. The plant from which we obtain the pyrethrum of the pharmacopœias; *Asterantium; Buphthalmum creticum; Bellis montana putescens acris; Dentaria; Herba salivaris; Pes Alexandrinus.* Spanish Chamomile; pellitory of Spain. *Anthemis:—caulibus simplicibus unifloris decumbentibus—foliis pinnato-multifidis*, of Linnæus. This root, though cultivated in this country, is generally imported from Spain. Its taste is hot and acrid, its acrimony residing in a resinous principle. The ancient Romans, it is said, employed the root of this plant as a pickle. In its recent state, it is not so pungent as when dried, and yet, if applied to the skin, it produces inflammation. Its qualities are stimulant; but it is never used, except as a masticatory, for relieving toothaches, rheumatic affections of the face, and paralysis of the tongue, in which it affords relief by stimulating the excretory ducts of the salival glands.

ANTHERA. (From ανθος, a flower.)

1. A compound medicine used by the ancients; so called from its florid colour.—*Galen. Ægineta.*

2. The male part of the frutification of plants:—so called by Linnæus, by way of eminence. The male genital organ of plants consists of three parts, the filament, anther, and pollen. The anthera is the little head or extremity which rests on the filament.

Different terms are applied to the anthers from their figure:

1. *Oblong;* as in *Lilium candidum.*
2. *Globose;* as in *Mercurialis annua.*
3. *Semilunar;* as in *Fragaria vesca.*
4. *Angular;* as in *Tulipa gesneriana.*
5. *Linear;* as in the grasses and *Protea.*
6. *Didymous;* as in *Digitalis purpurea.*
7. *Arrow-shaped;* as in *Crocus sativus.*
8. *Bifid*, parted half way down in two; as in the grasses and *Erica.*
9. *Shield-like* or *peltate*, of a round shape; as in *Taxus baccata.*
10. *Dentate*, with a tooth-like margin; as in *Taxus baccata.*
11. *Hairy;* as in *Lamium album.*
12. *Bicorn*, with two divisions like horns; as with *Arbutus uva ursi* and *Vaccinium myrtillus.*
13. *Cristate*, having cartilaginous points.
14. *Crucial;* as in *Mellitis.*
15. *Double* or *twin-like;* as in *Callisia* and *Hura.*
16. *Rostrate;* as in *Osbeckia.*
17. *Subulate*, or awl-shaped; as in the genus *Roella.*
18. *Cordate;* as in *Cupraria.*
19. *Reniform*, kidney-shaped; as in *Tradescantia* and *Ginora.*
20. *Trigonal*, or three-cornered; as in the *Rose.*
21. *Tetragonal*, or four-cornered; as in *Cannabis* and *Dictamnus.*

From their situation:

22. *Erect*, with its base upon the apex of the filament; as in *Tulipa gesneriana.*
23. *Incumbent*, lying horizontally upon the filament, as in *Amaryllis formossima.*
24. *Versatile*, when the incumbent anther adheres so loosely to the filament, that the least agitation of the plant puts it in motion; as in *Secale cereale.*
25. *Lateral*, adhering laterally to the filiment; as in *Dianthera.*
26. *Sessile*, the filament almost wanting; as in *Aristolochia clematitis.*
27. *Free*, not united to any other anther.
28. *Connate*, united together; as in *Viola odorata.*

ANTHODIUM. A species of calyx, which contains many flowers being common to them all. It is distinguished from its structure into,

1. *Monophyllous*, consisting of one leaflet perfect at its base, but cut at its limb or margin; as in *Tragopogon.*
2. *Polyphyllous*, consisting of several leaflets; as in *Carduus* and *Centaurea.*
3. *Simple*, consisting of one series of leaflets; as in *Cucalia porophyllum.*
4. *Equal*, when all the leaves of the *Anthodium simplex* are of the same length, as in *Ethulia.*
5. *Imbrecate* or *squamose*, as in *Centaurea cyanus.*
6. *Squarrose*, the leaflets bent backward at their extremities.
7. *Scabrous*, rough, consisting of dry leaflets; as in *Centaurea glastifolia* and *jacea.*
8. *Spinous*, the leaflets having thorns; as in *Cynaa scolymus* and *Centaurea sonchifolia.*
9. *Turbinate;* as in *Tarconanthus camphoratus.*
10. *Globose;* as in *Centaurea calcitrapa.*
11. *Hemispherical*, round below and flat above; as in *Anthemis* and *Chrysocoma.*
12. *Cylindrical*, long and round; as with *Eupatorium.*
13. *Calyculate*, the basis surrounded by another small leafy anthodium; as in *Leontodon taraxacum, Senecio*, and *Crepis.*

ANTHOPHYLLITE. A massive mineral, of a brown colour found at Konigsberg, in Norway.

ANTHOPHY'LLUS. (From ανθος, a flower, and φυλλον, a leaf; so called from the fragrance of the flowers and the beauty of the leaves.) The clove is so termed when it has been suffered to grow to maturity.—*Bauhin.*

ANTHOPHY'LLUS. (From ανθος, a flower, and φιλεω, to love.) A florist.

A'NTHORA. (*Quasi antithora.* Αντιθορα; from αντι, against, and θορα, monkshood: so called, because it is said to counteract the effects of the thora or monkshood.) A species of Wolfsbane. See *Anconitum anthora.*

A'NTHOS FLORES. The flowers of the *rosmarinus* are so termed in some pharmacopœias. See *Rosmarinus officinalis.*

ANTHRA'CIA. 1. The name of a genus of diseases in Good's Nosology. See *Nosology.*

2. A name of the carbuncle. See *Anthrax.*

ANTHRACITE. Blind coal, Kilkenny coal, or glance coal. There are three varieties, conchoidal, slaty, and columnal.

ANTHRACO'SIS OCULI. A red, livid, burning, sloughy, very painful tumour, occurring on the eyelids.—*Ægineta.*

ANTHRAX. (*Anthrax, acis. m.;* from ανθραξ, a burning coal.) *Anthracia; Anthrocosia; Anthrocoma; Carbunculus; Carbo; Rubinus versus; Codisella; Granatristum; Pruna;*

Persicus ignus of Avicenna. A hard and circumscribed inflammatory tubercle like a boil, which sometimes forms on the cheek, neck, or back, and in a few days becomes highly gangrenous. It then discharges an extremely fœtid sanies from under the black core, which, like a burning coal, continues destroying the surrounding parts. It is supposed to arise from a peculiar miasma, is most common in warm climates, and often attends the plague.

ANTHROPOGRA′PHY. (*Anthropographia;* from *ανθρωπος*, a man, and *γραφω*, to write.) Description of the structure of man.

ANTHROPOLO′GY. (*Anthropologia;* from *ανθρωπος*, a man, and *λογος*, a discourse.) The description of man.

ANTHYPNO′TIC. (*Anthypnoticus;* from *αντι*, against, and *υπνος*, sleep.) That which prevents sleep or drowsiness.

ANTHYPOCHONDRI′AC, (*Anthypochondriacus;* from *αντι*, against, and *ὑποχονδρια*, the hypochondria.) That which is adapted to cure low-spiritedness or disorders of the hypochondria.

ANTHYSTE′RIC. (*Anthystericus;* from *αντι*, against, and *υϛερα*, the womb.) That which relieves the hysteric passion.

A′NTI. (Αντι, against.) There are many names compounded with this word, as *Antiasthmatic; Antihysteric; Antidysenteric*, &c. which signify medicines against the asthma, hysterics, dysentery, &c.

ANTI′ADES. (From *αντιαω*, to meet.) 1. The tonsils are so called, because they answer one another.

2. The mumps.—*Nic. Piso.*

ANTIA′GRA. (From *αντιας*, a tonsil, and *αγρα*, a prey.) *Antiagri*. A tumour of the tonsils.—*Ulpian, Roland*, &c.

ANTIARTHRI′TIC. (*Antiarthriticus;* from *αντι*, against, and *αρθριτις*, the gout. Antarthritic. Against the gout.

ANTIASTHMATIC. (*Antiasthmaticus;* from *αντι*, against, and *ασθμα*, an asthma.) Antasthmatic. Against the asthma.

ANTIATROPHIC. (*Antiatrophicus;* from *αντι*, against, and *ατροφια*, an atrophy.) Against an atrophy or wasting away.

ANTICACHE′CTIC. (*Anticachecticus*, from *αντι*, against, and *καχεξια*, a cachexy.) Medicines against a cachexy, or bad habit of body.

ANTICA′RDIUM. (From *αντι*, against, or opposite, and *καρδια*, the heart.) The hollow at the bottom of the breast, commonly called scrobiculus cordis, or pit of the stomach.

ANTICATARRHA′L. (*Anticatarrhalis;* from *αντι*, against, and *καταρρος*, a catarrh.) That which relieves a catarrh.

ANTICAUSO′TIC. (From *αντι*, against, and *καυσος*, a burning fever.) Remedies against burning fevers. We read, in Corp. Pharm. of Junken, of a *syrupus anticausoticus*.

A′NTICHEIR. (From *αντι*, against, and *χειρ*, the hand.) The thumb.—*Galen.*

ANTICNE′MION. (From *αντι*, against, or opposite, and *κνημη*, the calf of the leg.) That part of the tibia which is bare of flesh, and opposite the calf of the leg. The shin-bone.—*Galen.*

ANTICO′LIC. (From *αντι*, against, and *κωλικη*, the colic.) Remedies against the colic.

ANTIDIA′STOLE. (From *αντι*, against, and *διαϛελλω*, to distinguish.) An exact and accurate distinction of one disease, or symptom, from another.

ANTIDI′NIC. (From *αντι*, against, and *δινος*, circumgyration.) Medicines against a vertigo, or giddiness.—*Blanchard.*

ANTIDOTARIUM. (*Antidotarium, i.* n.; from *αντιδοτος*, an antidote.) A term used by former writers, for what we now call a dispensatory; a place where antidotes are prescribed and prepared. There are antidotaries extant of several authors, as those of *Nicholaus, Mesue, Myrepsus*, &c.

ANTI′DOTUS. (From *αντι*, against, and *διδωμι*, to give.) 1. An antidote.

2. A preservative against sickness.

3. A remedy.—*Galen.*

ANTIDYSENTE′RIC. (*Antidysentericus;* from *αντι*, against, and *δυσεντερια*, a flux.) Medicines against a dysentery.

ANTIEMETIC. (*Antiemeticus;* from *αντι*, against, and *εμεω*, to vomit.) Antemetic. That which prevents or stops vomiting.

ANTIEPHIALTIC. (*Antiephialticus;* from *αντι*, against, and *εφιαλτης*, the night-mare.) Antephialtic. Against the night-mare.

ANTIEPILEPTIC. (*Antiepilepticus;* from *αντι*, against, and *επιληψις*, the epilepsy.) Antepileptic. Against epilepsy.

ANTIFEBRI′LE. (*Antifebrilis;* from *αντι*, against, and *febris*, a fever.) A febrifuge, a remedy against fever.

ANTIHE′CTIC. (*Antihecticus;* from *αντι*, against, and *ἑκτικος*, a hectic fever.) A remedy against a hectic fever.

ANTIHE′CTICUM POTERII. *Antimonium diaphoreticum Joviale*. A medicine invented by Poterius, formerly extolled as effectual in hectic fevers, but now disregarded. It is an oxyde of tin and chalybeated regulus of antimony, in consequence of their deflagration with nitre.

ANTIHE′LIX. (*Antihelix, licis.* m.; from *αντι*, against, and *ελιξ*, the helix.) The inner circle of the external ear, so called from its opposition to the outer circuit, called the helix.

ANTIHELMIN′TIC. See *Anthelmintic.*

ANTIHYSTER′IC. (*Antihystericus;* from *αντι*, against, and *ὑϛερικα*, hysterics.) Medicines which prevent or relieve hysterics.

ANTILE′PSIS. (From *αντιλαμβανω*, to take hold.of) The securing of bandages or ligatures from slipping.—*Hippocrates.*

ANTILO′BIUM. (From *αντι*, opposite, and *λοβος*, the bottom of the ear.) The tragus or that part of the. ear which is opposite the lobe.

ANTILOI′MIC. (*Antiloimicus;* from *αντι*, against, and *λοιμος*, the plague.) Remedies or preventives against the plague.

ANTI′LOPUS. The antelope. An African beast resembling a deer, the hoofs and horns of which were formerly given in hysteric and epileptic cases.

ANTILY′SSUS. (From *αντι*, against, and *λυσσα*, the bite of a mad dog.) A medicine or remedy against the bite of a mad dog.

ANTIMONIA′L. (*Antimonialis;* rom *antimonium*, antimony.) An antimonial or composition in which antimony is a chief ingredient. A preparation of antimony.

Antimonial powder. See *Antimonialis pulvis.*

ANTIMONIA′LIS PULVIS. Antimonial powder. Take of sulphuret of antimony, powdered, a pound; hartshorn shavings, two pounds. Mix and throw them into a broad iron pot heated to a white heat, and stir the mixture constantly until it acquires an ash colour. Having taken it out, reduce it to powder, and put it into a coated crucible, upon which another inverted crucible, having a small hole in its bottom, is to be luted. Then raise the fire by degrees to a white heat, and keep it so for two hours. Reduce the residuary mass to a very fine powder. The dose is from five to ten grains. It is in high esteem as a febrifuge, sudorific, and antispasmodic. The diseases in which it is mostly exhibited are, most species of asthenic and exanthematous fevers, acute rheumatism, gout, diseases arising from obstructed perspiration, dysuria, nervous affections, and spasms.

This preparation was introduced into the former London pharmacopœia as a substitute for a medicine of extensive celebrity, Dr. James's powder; to which, however, the present form more nearly assimilates in its dose, and it is more manageable in its administration, by the reduction of the proportion of antimony to one-half.

Antimonic acid. See *Antimony.*

Antimonious acid. See *Antimony.*

ANTIMONII OXYDUM. *Oxyde of Antimony.* This preparation is now directed to be made by dissolving an ounce of tartarised antimony, and two drams of subcarbonate of ammonia, separately in distilled water, mixing the solutions and boiling, till the oxyde of antimony is precipitated, which is to be washed with water, and dried. This must not be confounded with the old calcined or diaphoretic antimony, being a much more active preparation. See *Antimony.*

In its effects, it will be found to agree pretty much with the antimonium tartarisatum; but it is very little employed.

ANTIMONII SULPHURETUM PRÆCIPITATUM. *Sulphur antimonii præcipitatum.* Precipitated sulphuret of antimony. This preparation of antimony appears to have rendered that called kermes mineral unnecessary. It is made thus:—Take of sulphuret of antimony, in powder, two pounds;—of the solution of potassa, four pints:—of distilled water, three pints.

Mix; and boil the mixture over a slow fire for three hours, stirring it well, and occasionally adding distilled water, so that the same measure may be preserved. Strain the solution quickly through a double linen cloth, and while it is yet hot, drop in, gradually, as much sulphuric acid as may be required to precipitate the powder; then wash away the sulphate of potassa by hot water; dry the precipitated sulphuret of antimony, and reduce it to powder. In this process part of the water is decomposed, and its oxygen unites partly with the antimony; the oxyde of antimony, as well as the potassa, combines with sulphur and hydrogen, forming hydrosulphuret of antimony and hydroguretted sulphuret of potassa: if the solution be allowed to cool, the former of these partly precipitates, constituting the kermes mineral; but the addition of the sulphuric acid throws down the whole of it at once, mixed with some sulphur, furnished by the decomposition of the hydroguretted sulphuret of potassa.

As an alterative and sudorific, it is in high estimation, and given in diseases of the skin and glands; and, joined with calomel, it is one of the most powerful and penetrating alteratives we are in possession of.

ANTIMONII TARTARIZATI VINUM. Wine of tartarized antimony. Take of tartarized antimony, one scruple; boiling distilled water, eight fluid ounces; rectified spirit, two fluid ounces. Dissolve the tartarised antimony in the boiling distilled water, and add the spirit to the filtered liquor. Four fluid drachms of this contain one grain of tartarised antimony.

ANTIMONITE. A salt formed by the combination of the antimonous acid with alkaline and other bases. See *Antimony.*

ANTIMO'NIUM. See *Antimony.*

ANTIMONIUM CALCINATUM. An oxyde of antimony.

ANTIMONIUM DIAPHORETICUM. An old name for an oxyde of antimony.

ANTIMONIUM TARTARIZATUM. *Tartarus emeticus; Tartarum emeticum; Tartarus antimonialis; Tartris antimonii cum potassa; Tartarum stibiatum.* Tartar emetic. It is obtained by boiling the fusible oxyde of antimony with supertartrate of potassa, the excess of tartaric acid dissolves the oxyde, and a triple salt is obtained by crystallisation. The London Pharmacopœia directs thus: Take of glass of antimony finely levigated, supertartrate of potassa in powder, of each a pound; boiling distilled water a gallon; mix the glass of antimony and the supertartrate of potassa well together, and then add them by degrees to the distilled water, which is to be kept boiling and constantly stirred; boil the whole for a quarter of an hour, and then set it by. Filter it when cold, and evaporate the filtered liquor so that crystals may form in it. A solution of this salt in dilute wine is ordered in the Pharmacopœia. See *Antimonii tartarizati vinum.*

Tartar emetic is the most useful of all the antimonial preparations. Its action is not dependent on the state of the stomach, and, being soluble in water, its dose is easily managed, while it also acts more speedily. In doses of from one to three, four, or five grains, it generally acts powerfully as an emetic, and is employed whenever we wish to obtain the effects which result from full vomiting. As patients are differently affected by this medicine, the safest mode of exhibiting it is: ℞. *Antimonii tartarizati*, gr. iii. *Aquæ distillatæ*, ℥iv. Misce et cola. Dosis ℥ss. omni horæ quadrante, donec supervenerit vomitus.

For children, emetic tartar is not so safe for an emetic as ipecacuanha powder: when great debility of the system is present, even a small dose has been known to prove fatal. Sometimes it proves cathartic. In smaller doses it excites nausea, and proves a powerful diaphoretic and expectorant. As an emetic it is chiefly given in the beginning of fevers and febrile diseases; when great debility is present, and in the advanced stages of typhoid fever, its use is improper, and even sometimes fatal. As a diaphoretic, it is given in small doses, of from an eighth to a quarter of a grain; and as an expectorant, in doses still smaller. Emetic tartar, in small doses, combined with calomel, has been found a powerful yet safe alterative in obstinate eruptions of the skin. ℞. *Antimonii tartarizati*, gr. iv. *Hydrargyri submuriatis*, gr. xvi. *Confectionis rosæ gallicæ*, q. s. Divide in pil. xxiv. Capiat i. mane nocteque ex thea sassafras.

In the form of powder, or dissolved in water, it is applied by a pencil to warts and obstinate ulcers: it is also given in the form of clyster, with a view to produce irritation in soporose diseases, apoplexy, ileus, and strangulated hernia. The powder mixed with any fluid, and rubbed on the scrobiculus cordis, excites vomiting. Another property which tartar emetic has, when rubbed on the skin, is that of producing a crop of pustules very like to the small-pox, and with this view it is used against rheumatic pains, white, and other obstinate swellings. The best antidote against the bad effects of too large a quantity of this and other antimonial preparations, is a decoction of the bark of cinchona: in defect of which, tea and other astringents may be used. In a larger dose, this salt is capable of acting as a violent poison. The best antidotes are demulcent drinks, infusions of bark, tea, and sulphuretted hydrogen water, which instantly converts the energetic salt into a relatively mild sulphuret: anodynes are useful afterwards.

Antimonium vitrifactum. Glass of antimony. An oxyde of antimony, with a little sulphuret.

ANTIMONY. (*Antimonium*, *i.* n. Αντιμονιον. The origin of this word is very obscure. The most received etymology is, from *αντι*, against, and *μονος*, a monk; because Valentine, by an injudicious administration of it, poisoned his brother monks.) *Stibium.* A metal found *native*, but very rarely; it has, in that state, a metallic lustre, and is found in masses of different shapes; its colour is white, between those of tin and silver. It generally contains a small portion of arsenic. It is likewise met with in the state of an oxyde, *antimonial ochre*. The most abundant ore of it is that in which it is combined with sulphur, *the gray ore of antimony*, or *sulphuret of antimony*. The colour of this ore is bluish, or steel-gray, of a metallic lustre, and often extremely beautifully variegated. Its texture is either compact, foliated, or striated. The striated is found both crystallised, massive, and disseminated: there are many varieties of this ore.

Properties of Antimony.—Antimony is a metal of a grayish white, having a slight bluish shade, and very brilliant. Its texture is lamellated, and exhibits plates crossing each other in every direction. Its surface is covered with herbarisations and foliage. Its specific gravity is 6.702. It is sufficiently hard to scratch all the soft metals. It is very brittle, easily broken, and pulverisable. It fuses at 810° Fahr. It can be volatilised, and burns by a strong heat. When perfectly fused, and suffered to cool gradually, it crystallises in octahedra. It unites with sulphur and phosphorus. It decomposes water strongly at a red heat. It is soluble in alkaline sulphurets. Sulphuric acid, boiled upon antimony, is feebly decomposed. Nitric acid dissolves it in the cold. Muriatic acid scarcely acts upon it. The oxygenated muriatic acid gas inflames it, and the liquid acid dissolves it with facility. Arsenic acid dissolves it by heat with difficulty. It unites, by fusion, with gold, and renders it pale and brittle. Platina, silver, lead, bismuth, nickel, copper, arsenic, iron, cobalt, tin, and zinc, unite with antimony by fusion, and form with it compounds, more or less brittle. Mercury does not alloy with it easily unless very pure. We are little acquainted with the action of alkalies upon it. Nitrate of potassa is decomposed by it. It fulminates by percussion with oxygenated muriate of potassa. Antimony forms three, probably four, distinct combinations with oxygen:

1. The *protoxyde*, a blackish gray powder obtained from a mixture of powder of antimony and water at the positive pole of a voltaic circuit.

2. The *deutoxyde*, obtained by digesting the metal in powder in muriatic acid, and pouring the solution in water of potassa. Wash and dry the precipitate. It is a powder of a dirty white colour which melts it a moderate red heat, and crystallises as it cools.

3. The *tritoxyde*, or *antimonious acid*, which as immediately produced by the combustion of the metal, called formerly, from its fine white colour, the argentine flowers of antimony. It forms the salts called *antimonites* with the different bases.

4. The *peroxyde*, or *antimonic acid*. This is formed when the metal in powder is ignited along with six times its weight of nitre in a silver crucible. The excess of potassa and nitre being afterwards separated by hot water, the antimoniate of potassa is then to be decomposed by muriatic acid, when the insoluble antimonic acid of a straw colour will be obtained.

Methods of obtaining antimony.—1. To obtain antimony, heat 32 parts of filings of iron to redness, and project on them, by degrees, 100 parts of antimony; when the whole is in fusion, throw on it, by degrees, 20 parts of nitrate of potassa, and after a few minutes quiet fusion, pour it into an iron melting cone, previously heated and greased.

2. It may also be obtained by melting eight parts of the ore mixed with six of nitrate of potassa, and three of supertartrate of potassa, gradually projected into a red-hot crucible, and fused.

To obtain perfectly pure antimony, Margraaf melted some pounds of the sulphuret in a luted crucible, and thus scorified any metals it might contain. Of the antimony thus purified, which lay at the bottom, he took sixteen ounces, which he oxydised cautiously, first with a slow, and afterwards with a strong heat, until it ceased to smell of sulphur, and acquired a grayish-white colour. Of this gray powder he took four ounces, mixed them with six drachms of supertartrate of potassa, and three of charcoal, and kept them in fusion in a well-covered and luted crucible, for one hour, and thus obtained a metallic button that weighed one ounce, seven drachms, and twenty grains.

The metal, thus obtained, he mixed with half its weight of desiccated subcarbonate of soda, and covered the mixture with the same quantity of the subcarbonate. He then melted it in a well-covered and luted crucible, in a very strong heat, for half an hour, and thus obtained a button which weighed one ounce, six drachms, and seven grains, much whiter and more beautiful than the former. This he again treated with one and a half ounce of subcarbonate of soda, and obtained a button, weighing one ounce, five drachms, and six grains. This button was still purer than the foregoing. Repeating these fusions with equal weights of subcarbonate of soda three times more, and an hour and a half each time, he at last obtained a button so pure as to amalgamate with mercury with ease, very hard, and in some degree malleable; the scoriæ formed in the last fusion were transparent, which indicated that they contained no sulphur, and hence it is the obstinate adherence of the sulphur that renders the purification of this metal so difficult.

"Chlorine gas and antimony combine with combustion, and a *bichloride* results. This was formerly prepared by distilling a mixture of two parts of corrosive sublimate with one of antimony. The substance which came over having a fatty consistence, was called *butter of antimony*. It is frequently crystallised in four-sided prisms. It is fusible and volatile at a moderate heat; and is resolved by water alone into the white oxyde and muriatic acid. Being a bichloride, it is eminently corrosive, like the bichloride of mercury, from which it is formed. It consists of 45.7 chlorine + 54.3 antimony, according to Dr. John Davy's analysis, when the composition of the sulphuret is corrected by its recent exact analysis by Berzelius. But 11 antimony + 2 primes chlorine = 9.0, give the proportion per cent. of 44.1 + 55.5; a good coincidence, if we consider the circuitous process by which Dr. Davy's analysis was performed. Three parts of corrosive sublimate, and one of metallic antimony, are the equivalent proportions for making butter of antimony.

Iodine and antimony combine by the aid of heat into a solid *iodine*, of a dark red colour.

The *phosphuret* of this metal is obtained by fusing it with solid phosphoric acid. It is a white semicrystalline substance. The sulphuret of antimony exists abundantly in nature. It consists, according to Berzelius, of 100 antimony + 37.25 sulphur. The proportion given by the equivalent ratio is 100 + 36.5. The only important alloys of antimony are those of lead and tin; the former constitutes type-metal, and contains about one-sixteenth of antimony; the latter alloy is employed for making the plates on which music is engraved.

The salts of antimony are of two different orders; in the first, the deutoxyde acts the part of a salifiable base; in the second, the tritoxyde and peroxyde act the part of acids, neutralizing the alkaline and other bases, to constitute the antimonites and antimoniates.

The only distinct combination of the first order entitled to our attention, is the triple salt called *tartrate of potassa and antimony*, or tartar emetic, and which, by Gay Lussac's new views, would be styled cream-tartrate of antimony. This constitutes a valuable and powerful medicine, and therefore the mode of preparing it should be correctly and clearly defined. As the dull white deutoxyde of antimony is the true basis of this compound salt, and as that oxyde readily passes by mismanagement into the tritoxyde or antimonious acid, which is altogether unfit for the purpose, adequate pains should be taken to guard against so capital an error. In the British Pharmacopœias, the glass of antimony is now directed as the basis of tartar emetic. More complex and precarious formulæ were formerly introduced. The new edition of the Pharmacopée Française has given a recipe, which appears, with a slight change of proportions, to be unexceptionable. Take of the sulphuretted vitreous oxyde of antimony, levigated and acidulous tartrate of potassa, equal parts. From a powder, which is to be put into an earthen or silver vessel, with a sufficient quantity of pure water. Boil the mixture for half an hour, adding boiling water from time to time; filter the hot liquor, and evaporate to dryness in a porcelain capsule; dissolve in boiling water the result of the evaporation, evaporate till the solution acquires the spec. grav. 1.161, and then let it repose, that crystals be obtained, which, by this process, will be pure. By another recipe, copied, with some alteration, from Mr. Phillips's prescription, into the appendix of the French Pharmacopœia, a subsulphate of antimony is formed first of all, by digesting two parts of sulphuret of antimony in a moderate heat, with three parts of oil of vitriol. This insoluble subsulphate being well washed, is then digested in a quantity of boiling water, with its own weight of cream of tartar, and evaporated at the density 1.161, after which it is filtered hot. On cooling, crystals of the triple tartrate are obtained. One might imagine, that there is a chance of obtaining by this process a mixture of sulphate of potassa, and perhaps of a triple sulphate of antimony, along with the tartar emetic. Probably this does not happen, for it is said to yield crystals, very pure, very white, and without any mixture whatever.

Pure tartar emetic is in colourless and transparent tetrahedrons or octohedrons. It reddens litmus. Its taste is nauseous and caustic. Exposed to the air, it effloresces slowly. Boiling water dissolves half its weight, and cold water a fifteenth part. Sulphuric, nitric, and muriatic acids, when poured into a solution of this salt, precipitate its cream of tartar; and soda, potassa, ammonia, or their carbonates, throw down its oxyde of antimony. Barytes, strontites, and lime waters occasion not only a precipitate of oxyde of antimony, like the alkalies, but also insoluble tartrates of these earths. That produced by the alkaline hydrosulphurets is wholly formed of kermes; while that caused by sulphuretted hydrogen, contains both kermes and cream of tartar. The decoctions of several varieties of cinchona, and of several bitter and astringent plants, equally decompose tartar emetic; and the precipitate then always consists of the oxyde of antimony, combined with the vegetable matter and cream of tartar. Physicians ought, therefore, to beware of such incompatible mixtures. When tartar emetic is exposed to a red heat, it first blackens, like all organic compounds, and afterwards leaves a residuum of metallic antimony and subcarbonate of potassa. From this circumstance, and the deep brownish red precipitate, by hydrosulphurets, this antimonial combination may readily be recognised. The precipitate may further be dried on a filter, and ignited with black flux, when a globule of metallic antimony will be obtained. Infusion of galls is an active precipitant of tartar emetic.

The composition of this salt, according to M. Thenard, is 35.4 acid, 39.6 oxyde, 16.7 potassa, and 8.2 water. The presence of the latter ingredient is obvious, from the undisputed phenomenon of efflorescence. If we adopt the new views of M. Gay Lussac, this salt may be a compound of a prime equivalent of tartar = 23.825, with a prime equivalent of deutoxyde of antimony = 13. On this hypothesis, we would have the following proportions:

2 primes acid,	= 16.75	45.4
1 prime potassa,	= 5.95	16.2
1 prime water,	= 1.125	3.1
1 oxyde of antimony,	= 13.00	35.3
	36.825	100.0

But very little confidence can be reposed in such atomical representations.

The deutoxyde seems to have the property of combining with sulphur in various proportions. To this species of compound must be referred the liver of antimony, glass of antimony, and *crocus metallorum* of the ancient apothecaries. Sulphuretted hydrogen forms, with the deutoxyde of antimony, a compound which possessed at one time great celebrity in medicine, and of which a modification has lately been introduced into the art of calico printing. By dropping hydrosulphuret of potassa, or of ammonia, into the cream tartrate, or into mild muriate of antimony, the hydrosulphuret of the metallic oxyde precipitates of a beautiful deep orange colour. This is *kermes mineral*. Cluzel's process for obtaining a fine *kermes*, light, velvety, and of a deep purple-brown, is the following: one part of pulverised sulphuret of antimony, 22½ parts of crystallised subcarbonate of soda, and 200 parts of water, are to be boiled together in an iron pot. Filter the hot liquor into warm earthen pans, and allow them to cool very slowly. At the end of 24 hours, the kermes is deposited. Throw it on a filter, wash it with water which had been boiled and then cooled out of contact with air. Dry the kermes at a temperature of 85°, and preserve in corked phials. Whatever may be the process employed, by boiling the liquor, after cooling and filtration, on new sulphuret of antimony, or upon that which was left in the former operation, this new liquid will deposit, on cooling, a new quantity of kermes. Besides the hydrosulphuretted oxyde of antimony, there is formed a sulphuretted hydrosulphuret of potassa or soda. Consequently, the alkali seizes a portion of the sulphur from the antimonial sulphuret, water is decomposed; and, whilst a portion of its hydrogen unites to the alkaline sulphuret, its oxygen, and the other portion of its hydrogen, combine with the sulphuretted antimony. It seems, that the resulting kermes remains dissolved in the sulphuretted hydrosulphuret of potassa or soda; but as it is less soluble in the cold than the hot, it is partially precipitated by refrigeration. If we pour into the supernatant liquid, after the kermes is deposited and removed, any acid, as the dilute nitric, sulphuric, or muriatic, we decompose the sulphuretted hydrosulphuret of potassa or soda. The alkaline base being laid hold of, the sulphuretted hydrogen and sulphur to which they were united are set at liberty; the sulphur and kermes fall together, combine with it, and form an orange-coloured compound, called the golden sulphuret of antimony. It is a hydroguretted sulphuret of antimony. Hence, when it is digested with warm muriatic acid, a large residuum of sulphur is obtained, amounting sometimes to 12 per cent. Kermes is composed, by Thenard, of 20.3 sulphuretted hydrogen, 4.15 sulphur, 72.76 oxyde of antimony, 2.79 water and loss; and the golden sulphuret consists of 17.87 sulphuretted hydrogen, 68.3 oxyde of antimony, and 12 sulphur.

By evaporating the supernatant kermes liquid, and cooling, crystals form, which have been lately employed by the calico printer to give a topical orange. These crystals are dissolved in water, and the solution, being thickened with paste or gum, is applied to cloth in the usual way. When the cloth is dried, it is passed through a dilute acid, when the orange precipitate is deposited and fixed on the vegetable fibres.

An empirical antimonial medicine, called James's powder, has been much used in this country. The inventor called it his *fever powder*, and was so successful in his practice with it, that it obtained very great reputation, which it still in some measure retains. Probably, the success of Dr. James was in great measure owing to his free use of the bark, which he always gave as largely as the stomach would bear, as soon as he had completely evacuated the primæ viæ by the use of his antimonial preparation, with which at first he used to combine some mercurial. His specification, lodged in Chancery, is as follows: "Take antimony, calcine it with a continued protracted heat, in a flat, unglazed, earthen vessel, adding to it from time to time a sufficient quantity of any animal oil and salt, well dephlegmated; then boil it in melted nitre for a considerable time, and separate the powder from the nitre by dissolving it in water." The real recipe has been studiously concealed, and a false one published in its stead. Different formulæ have been offered for imitating it. That of Dr. Pearson furnishes a mere mixture of an oxyde of antimony, with phosphate of lime. The real powder of James, according to this chemist, consists of 57 oxyde of antimony, with 43 phosphate of lime. It seems highly probable that superphosphate of lime would act on oxyde of antimony in a way somewhat similar to cream of tartar, and produce a more chemical combination than what can be derived from a precarious ustulation, and calcination, of hartshorn shavings and sulphuret of antimony, in ordinary hands. The antimonial medicines are powerful deobstruents, promoting particularly the cuticular discharge. The union of this metallic oxyde with sulphuretted hydrogen, ought undoubtedly to favour its medicinal agency in chronic diseases of the skin. The kermes deserves more credit than it has hitherto received from British physicians.

The compounds, formed by the antimonious and antimonic acids with the bases, have not been applied to any use. Muriate of barytes may be employed as a test for tartar emetic. It will show, by a precipitate insoluble in nitric acid, if sulphate of potassa be present. If the crystals be regularly formed, more tartar need not be suspected."—*Ure's Chem. Dict.*

The preparations of antimony formerly in use were very many: those now directed to be kept are:—

1. *Sulphuretum antimonii.*
2. *Oxydum antimonii.*
3. *Sulphuretum antimonii præcipitatum.*
4. *Antimonium tartarizatum.*
5. *Vinum antimonii tartarizati.*
6. *Pulvis antimonialis.*

ANTI′MORIS. (From *αντι*, against, and *μορος*, death, or disease.) A medicine to prolong life.

ANTINEPHRI′TIC. (*Antinephriticus*; from *αντι*, against, and *νεφριτις*, a disease of the kidneys.) A remedy against disorders of the kidneys.

ANTIODONTALGIC. (*Antiodontalgicus*; from *αντι*, against, and *οδονταλγια*, the toothache.) Against the toothache.

ANTIODONTA′LGICUS. An insect described by Germi in a small work published at Florence 1794, so called from its property of allaying the toothache. It is a kind of curculio found on a species of thistle, *Carduus spinosissimus*. If twelve or fifteen of these insects, in the state of larvæ, or when come to perfection, be bruised and rubbed slowly between the forefinger and thumb until they have lost their moisture, and if the painful tooth, where it is hollow, be touched with that finger, the pain ceases sometimes instantaneously. A piece of shamoy leather will answer the same purpose with the finger. If the gums are inflamed, the remedy is of no avail. Other insects possess the property of curing the toothache; such as the *Scarabeus ferrugineus* of Fabricius; the *Coccinella septempunctata*, or lady-bird; the *Chrysomela populi*, and the *Chrysomela sanguinolenta*. This property belongs to several kinds of the *Coleoptera*.

ANTIPARALY′TIC. (*Antiparalyticus*; from *αντι*, against, and *παραλυσις*, the palsy.) Against the palsy.

ANTIPATHY. (*Antipathia, æ. f.* Αντιπαθης, from αντιπαθεώ, to have a natural repugnance or dislike; from *αντι*, against, and *παθος*, an affection.) 1. An aversion to particular objects.

2. The name of a genus of diseases in some classifications.

ANTIPERISTA′LTIC. *Antiperistalticus*; from *αντι*, against, and *περιςελλω*, to contract.) Whatsoever obstructs the peristaltic motion of the intestines.

ANTIPERI′STATIS. (From *αντι*, against, and *περιςημι*, to press.) A compression on all sides. *Theophrastus de igne.*

ANTIPHA′RMIC. (*Antipharmicus*; from *αντι*, against, and *φαρμακον*, a poison.) The same as alexipharmic. Remedies or preservatives against poison.—*Dioscorides.*

ANTIPHLOGI′STIC. (*Antiphlogisticus*; from *αντι*, against, and *φλεγω*, to burn. A term applied to those medicines, plans of diet, and other circumstances, which tend to oppose inflammation, or which, in other words, weaken the system by diminishing the activity of the vital power.

ANTIPHTHI′SIC. (*Antiphthisicus*; from *αντι*, against, and *φθισις*, consumption.) Against a consumption.

ANTI′PHTHORA. (From *αντι*, against, and φθορα, corruption.) A species of wolfsbane which resists corruption. See *Aconitum anthora.*

ANTIPHY'SIC. (*Antiphysicus*; from αντι, against, and φυσαω, to blow.) A carminative or remedy against wind.

ANTIPLEURI'TIC. (*Antipleuriticus*; from αντι, against, and πλευριτις, pleurisy.) Against a pleurisy.

ANTIPODA'GRIC. (*Antipodagricus*; from αντι, against, and ποδαγρα, the gout.) That which relieves or removes the gout.

Antipraxia. (From αντι, against, and πρασσω, to work.) A contrariety of functions and temperaments in divers parts. Contrariety of symptoms.

ANTIPYRE'TIC. (*Antipyreticus*; from αντι, against, and πυρετος, fever.) Against a fever.

Antiquartana'ria. (From αντι, against, and *quartana*, a quartan fever.) Remedies against quartan agues.

Antiqua'rticum. The same as Antiquartanaria.

ANTIRRHI'NUM. (Αντιῤῥινον; from αντι, against, and ῥις, the nose: so called because it represents the nose of a calf.) The name of a genus of plants in the Linnæan system. Class, *Didynamia*; Order, *Angiospermia.*

Antirrhinum elatine. The systematic name of the plant we call fluellen, or female speedwell. *Elatine* of the shops. The leaves of this plant have a roughish bitter taste, but no smell. It was formerly much used against scurvy and old ulcerations, but now wholly forgotten.

Antirrhinum linaria. The systematic name for the *linaria* of the pharmacopœias. *Osyris*; *Urinaria*; *Antirrhinum—foliis lanceolatis linearibus confertis, caule erecto, spicis terminalibus sessilibus, floribus imbricatis* of Linnæus. Common toad-flax. A perennial indigenous plant, common in barren pastures, hedges, and the sides of roads, flowering from July to September. The leaves have a bitterish and somewhat saline taste, and when rubbed between the fingers, have a faint smell, resembling that of elder. They are said to be diuretic and cathartic, and in both characters to act powerfully, especially in the first; hence the name *urinaria.* They have been recommended in dropsies and other disorders requiring powerful evacuations. The linaria has also been used as a resolvent in jaundice, and such diseases as were supposed to arise from visceral obstructions. But the plant has been chiefly valued for its effects when externally applied, especially in hæmorrhoidal affections, for which both the leaves and flowers have been employed in various forms of ointment, fomentation, and poultice. Dr. Wolph first invented an ointment of this plant for the piles. The Landgrave of Hesse, to whom he was physician, constantly interrogated him, to discover its composition; but Wolph obstinately refused, till the prince promised to give him a fat ox annually for the discovery: hence, to the following verse, which was made to distinguish the linaria from the escula, viz.

"*Esula lactescit, sine lacte linaria crescit.*"

The hereditary Marshal of Hesse, added,

"*Esula nil nobis, sed dat linaria taurum.*"

ANTISCO'LIC. (*Antiscolicus*; from αντι, against, and σκωληξ, a worm.) Remedies against worms. See *Anthelmintic.*

ANTISCORBU'TIC. (*Antiscorbuticus*, from αντι, against, and *scorbutus*, the scurvy.) Medicines which cure the scurvy.

ANTISEPTIC. (*Antisepticus*, from αντι, against, and σηπω, to putrefy.) Whatever possesses a power of preventing animal substances from passing into a state of putrefaction, and of obviating putrefaction when already begun. This class of medicines comprehends four orders:

1. *Tonic antiseptics*; as cinchona, cusparia, chamæmelum, &c. which are suited for every condition of body, and are, in general, preferable to other antiseptics, for those with relaxed habits.

2. *Refrigerating antiseptics*; as acids, which are principally adapted for the young, vigorous, and plethoric.

3. *Stimulating antiseptics*; as wine and alkohol, best adapted for the old and debilitated.

4. *Antispasmodic antiseptics*; as camphor and asafœtida, which are to be selected for irritable and hysterical habits.

Anti'spasis. (From αντι, against, and σπαω, to draw.) A revulsion. The turning the course of the humours, whilst they are actually in motion.—*Galen.*

ANTISPASMODIC. (*Antispasmodicus*; from αντι, against, and σπασμος, a spasm.) Possessing the power of allaying, or removing, inordinate motions in the system, particularly those involuntary contractions which take place in muscles, naturally subject to the command of the will. Spasm may arise from various causes. One of the most frequent is a strong irritation, continually applied; such as dentition, or worms. In these cases, narcotics prove useful, by diminishing irritability and sensibility. Sometimes spasm arises from mere debility; and the obvious means of removing this is by the use of tonics. Both narcotics and tonics, therefore, are occasionally useful as antispasmodics, such as opium, camphor, and æther, in the one class, and zinc, mercury, and Peruvian bark, in the other. But there are, farther, several other substances, which cannot be with propriety referred to either of these classes; and to these, the title of antispasmodics is more exclusively appropriated. The principal antispasmodics, properly so called, are moschus, castoreum, oleum animale empyreumaticum, petroleum, ammonia, asafœtida, sagapenum, galbanum, valeriana, crocus, melaleuca leucadendron. The narcotics, used as antispasmodics, are æther, opium, camphor. The tonics, used as antispasmodics, are cuprum, zincum, hydrargyrum, cinchona.

ANTI'THENAR. (From αντι, against, and θεναρ, the palm of the hand or foot.) A muscle of the foot. See *Adductor pollicis pedis.*

ANTITRA'GICUS. *Antitragus.* One of the proper muscles of the ear, the use of which is to turn up the tip of the antitagrus a little outwards, and to depress the extremity of the antihelix towards it.

ANTITRAGUS. (*Antitragus*, *i.* m. from αντι, and τραγος, the tragus.) An eminence of the outer ear, opposite to the tragus.

ANTIVENE'REAL. (From αντι, against, and *venereus*, venereal.) Against the venereal disease.

ANTO'NII SANCTI IGNIS. (So called because St. Anthony was supposed to cure it miraculously. In the Roman missal, St. Anthony is implored as being the preserver from all sorts of fire.) St. Anthony's fire. See *Erysipelas.*

Antophy'llon. (From αντι, against, and φυλλον, a leaf; so called because its leaves are opposite.) The male caryophyllus.

A'NTRUM. (*Antrum*, *i.* n. a den or cave.) 1. A cavity which has a small opening into it.

2. The cochlea of the ear.

ANTRUM BUCCINOSUM. The cochlea of the ear.

ANTRUM GENÆ. See *Antrum of Highmore.*

ANTRUM HIGHMORIANUM. See *Antrum of Highmore.*

ANTRUM OF HIGHMORE. (From the name of an anatomist, who gave the first accurate description of it.) *Antrum Highmorianum; Antrum genæ; Sinus maxillaris pituitarius; Antrum maxillæ superioris.* Maxillary sinus. A large cavity in the middle of each superior maxillary bone, between the eye and the roof of the mouth, lined by the mucus membrane of the nose. See *Maxillare superius, os.*

One or both antra are liable to several morbid affections. Sometimes their membranous lining inflames, and secretes pus. At other times, in consequence of inflammation, or other causes, various excrescences and fungi are produced in them. Their bony parietes are occasionally affected with exostosis, or caries. Extraneous bodies may be lodged in them, and it is even asserted that insects may be generated in them, and cause, for many years, afflicting pains. Abscesses in the antrum are by far the most common. Violent blows on the cheek, inflammatory affections of the adjacent parts, and especially of the pituitary membrane lining the nostrils, exposure to cold and damp, and, above all things, bad teeth, may induce inflammation and suppuration in the antrum. The first symptom is a pain, at first imagined to be a tooth-ache, particularly if there should be a carious tooth at this part of the jaw. This pain, however, extends more into the nose than that usually does which arises from a decayed tooth; it also affects, more or less, the eye, the orbit, and the situation of the frontal sinuses. But even such symptoms are insufficient to characterise the disease, the nature of which is not unequivocally evinced, till a much later period. The complaint is, in general, of much longer duration than one entirely dependent on a caries of the tooth, and its violence increases more and more, until at last a hard tumour becomes perceptible below the cheek-bone. The swelling by degrees extends over the whole cheek; but it afterwards rises to a point, and forms a very circumscribed hardness, which may be felt above the back grinders. This symptom is accompanied by redness, and sometimes by inflammation and suppuration of the external parts. It is not uncommon also, for the outward abscess to communicate with that within the antrum. The circumscribed elevation of the tumour, however, does not occur in all cases. There are instances in which the matter makes its way towards the palate, causing the bones of the part to swell, and at length rendering them carious, unless timely assistance be given. There are other cases, in which the matter escapes between the fangs and sockets of the teeth. Lastly, there are other examples, in which matter, formed in the antrum, makes its exit at the nostril of the same side, when the patient is lying with his head on the opposite one, in a low position. If this mode of evacuation should be frequently repeated, it prevents the tumour both from pointing externally, and bursting, as it would do if the purulent matter could find no other vent. This evacuation of the pus from the nostril is not very common. The method of cure consists in extracting one of the dentes molares from the affected side; and then perforating through the socket into the bony cavity. A mild injection may afterwards be employed to cleanse the sinus occasionally.

ANTRUM MAXILLÆ. See *Antrum of Highmore.*

ANTRUM MAXILLARE. See *Antrum of Highmore.*

ANTRUM PYLORI. A concavity of the stomach approaching the pylorus.

ANTY'LION. (From *Antyllus*, its inventor.) An astringent application, recommended by Paulus Ægineta.

A'NUS. (*Anus, i.* masc. *quasi onus;* as carrying the burden of the bowels.)

1. The fundament; the lower extremity of the great intestine, named the rectum, is so called; and its office is to form an outlet for the fæces. The anus is furnished with muscles which are peculiar to it, viz. the *sphincter*, which forms a broad circular band of fibres, and keeps it habitually closed, and the *levatores ani*, which serve to dilate and draw it up to its natural situation, after the expulsion of the fæces. It is also surrounded, as well as the whole of the neighbouring intestine, with muscular fibres, and a very loose sort of cellular substance. The anus is subject to various diseases, especially piles, ulceration, abscesses, excrescences, prolapsus; and imperforation in new-born infants.

2. The term *anus* is also applied to a small opening of the third ventricle of the brain, which leads into the fourth.

ANUS, ARTIFICIAL. An accidental opening in the parietes of the abdomen, to which opening some part of the intestinal canal leads, and through which the fæces are either wholly or in part discharged. When a strangulated hernia occurs, in which the intestine is simply pinched, and this event is unknown; when it has not been relieved by the usual means; or when the necessary operation has not been practised in time; the protruded part becomes gangrenous, and the fæces escape. But if the patient should be at last operated upon, his fæces are discharged through the wound, and the intestines are more easily emptied. In both cases, the excrement continues to be discharged from the artificial opening. In this way an artificial anus is formed, through which the excrement is evacuated during life.

ANY'DRION. (From *α*, priv. and *υδωρ*, water; so called, because they who eat of it become thirsty.) A species of night-shade, according to Blancard.

ANYPEU'THYNUS. (From *α*, neg. and *υπευθυνος*, blameable.) Hippocrates, in his Precepts, uses this word to signify an accidental event, which cannot be charged on the physician, and for which he is not accountable.

AO'RTA. (*Aorta, æ.* f.; from *αηρ*, air, and *τηρεω*, to keep: so called because the ancients supposed that only air was contained in it.) The great artery of the body, which arises from the left ventricle of the heart, forms a curvature in the chest, and descends into the abdomen. See *Artery.*

APALACHI'NE GALLIS. (From *απαλλακω*, to repel; because it is supposed to repel infection.) See *Ilex cassine.*

APARI'NE. (From *ρινη*, a file; because its bark is rough, and rasps like a file.) Goose-grass. See *Galium aparine.*

APARTHRO'SIS. (From *απο* and *αρθρον*, a joint.) Articulation.

APATITE. A phosphate of lime mineral, of a white wine, yellow, green and red colour, found in primitive rocks in Cornwall and Devonshire.

APE'LLA. (From *α*, priv. and *pellis*, skin.) Shortness of the prepuce. Galen gives this name to all whose prepuce, either through disease, section, or otherwise, will not cover the glans.

APE′PSIA. (*Apepsia, æ.* f. Απεψια; from *α*, priv. and πεπτω, to digest.) Indigestion. See *Dyspepsia.*

APE′RIENS PALEABRARUM RECTUS. See *Levator palpebræ superioris.*

APERIENT. (*Aperiens;* from *aperio*, to open.) 1. That which gently opens the bowels.

2. Applied also to muscles, the office of which is to open parts; as the levator palpebræ superioris, which is called, in some anatomical works, aperiens palpebræ.

APERI′STATON. See *Aperistatus.*

APERI′STATUS. (From *α*, neg. and περιςημι, to surround.) *Aperistaton.* An epithet used by Galen, of an ulcer which is not dangerous, nor surrounded by inflammation.

APE′RTOR OCULI. See *Levator palpebræ superioris.*

APETALUS. (From *α*, priv. and *petalum*, a petal.) Without a petal or corol.

APETALÆ PLANTÆ. Plants without petals. The name of a division of plants in most systems of botany.

APEUTHY′SMENUS. (From απο and ευθυς, straight.) A name formerly given to the intestinum rectum, or straight gut.

A′PEX. 1. The extremity of a part; as the apex of the tongue, apex of the nose, &c.

2. The extremity of a leaf, *apex folii.*

3. The *anthera* of a flower of Tournefort, Rivinus, and Ray.

APHANI′SMUS. (From αφανιζω, to remove from the sight.) The removal, or gradual decay, of a disorder.

APHANITE. The name given by Haüy to a rock apparently homogeneous, but really compound, in which amphibole is the predominate principle.

APHÆ′RESIS. (From αφαιρεω, to remove.) This term was formerly much used in the schools of surgery, to signify that part of the art which consists in taking off any diseased or preternatural part of the body.

APHELXIA. (*Aphelxia, æ.* f.; from αφελκω, *abstraho*, to separate or abstract.) Revery. A genus of diseases in Good's classification constituted by absence or abstraction of mind. See *Nosolgy.*

APHEPSE′MA. (From απο, and εψω, to boil.) A decoction.

A′PHESIS. (From αφιημι, to remit.) The remission or termination of a disorder.

APHISTE′SIS. (From αφιςημι, to draw from.) An abscess.

Aphlogistic lamp. One which burns without flame.

A′PHODOS. (From απο, and οδος, departure.) Excrement. The dejection of the body.

APHO′NIA. (Αφωνια; from *α*, priv. and φωνη, the voice.) A suppression of the voice, without either syncope or comma. A genus of disease in the class *Locales*, and order *Dyscinesiæ*, of Cullen.

1. When it takes place from a tumour of the fauces, or about the glottis, it is termed *aphonia gutturalis.*

2. When from a disease of the trachea, *aphonia trachealis.*

3. And when from a paralysis, or want of nervous energy, *aphonia atonica.*

APHORIA. (*Aphoria, æ.* f.; from *α*, negative, and φερω, *fero, paris.*) Barrenness. The name of a genus of diseases in Good's new classification. See *Nosology.*

A′PHORISM. (*Aphorismus;* from αφοριζω, to distinguish.) A maxim, or principle, comprehended in a short sentence.

APHRITE. Earth foam. A carbonate of lime usually found in calcareous veins at Gera in Misnia and Thuringia.

APHRODI′SIA. (From Αφροδιτη, Venus.) An immoderate desire of venery.

APHRODISIAC. (*Aphrodisiacus;* from αφροδισια, venery.) That which excites a desire for venery.

APHRODISIA′STICON. (From αφρος, froth.) A troch so called by Galen, because it was given in dysenteries, where the stools were frothy.

APHRODI′SIUS MORBUS. (From Αφροδιτη, Venus.) The venereal disease.

APHTHA. (*Aphtha, æ.* f. Αφθαι; from απτω, to inflame.) The thrush. Frog, or sore mouth. *Aphtha lactucimen* of Sauvages. *Ulcera serpentia oris*, or spreading ulcers in the mouth, of Celsus. *Pustula oris. Alcola. Vesiculæ gingivarum Acacos. Aphtha infantum.* A disease ranked by Cullen in the class *Pyrexiæ*, order *Exanthemata.* Children are very subject to it. It appears in small, white ulcers upon the tongue, gums, and around the mouth and palate, resembling small particles of curdled milk. When the disease is mild, it is confined to these parts; but when it is violent and of long standing, it is apt to extend through the whole course of the alimentary canal, from the mouth down to the anus; and so to excite severe purgings, flatulencies, and other disagreeable symptoms. The disease, when recent and confined to the mouth, may in general be easily removed; but when of long standing, and extending down to the stomach and intestines, it very frequently proves fatal.

The thrush sometimes occurs as a chronic disease, both in warm climates and in those northern countries where the cold is combined with a considerable degree of moisture, or where the soil is of a very marshy nature. It may, in some cases, be considered as an idiopathic affection; but it is more usually symptomatic. It shows itself, at first, by an uneasy sensation, or burning heat in the stomach, which comes on by slow degrees, and increases gradually in violence. After some time, small pimples, of about the size of a pin's head, show themselves on the tip and edges of the tongue; and these, at length, spread over the whole inside of the mouth, and occasion such a tenderness and rawness, that the patient cannot take any food of a solid nature; neither can he receive any vinous or spirituous liquor into his mouth, without great pungency and pain being excited; little febrile heat attends, but there is a dry skin, pale countenance, small pulse, and cold extremities. These symptoms will probably continue for some weeks, the general health being sometimes better and sometimes worse, and then the patient will be attacked with acid eructations, or severe purgings, which greatly exhaust his strength, and produce considerable emaciation of the whole body. After a little time, these symptoms cease, and he again enjoys better health; but, sooner or later, the acrid matter shows itself once more in the mouth, with greater virulence than before, and makes frequent translations to the stomach and intestines, and so from these to the mouth again, until, at last, the patient is reduced to a perfect skeleton. Elderly people, and persons with a shattered constitution, are most liable to its attacks. The treatment of the thrush in children is generally to be begun by the exhibition of a gentle emetic: then clear the bowels, if confined, by rhubarb and magnesia, castor oil, or other mild aperients; or sometimes in gross torpid habits by a dose of calomel. In general the prevalence of acid in the primæ viæ appears to lead to the complaint; whence antacid remedies prove beneficial in its progress: when the patient is costive, giving the preference to magnesia; when relaxed, to chalk, which may be sometimes joined with aromatics, the mild vegetable astringents, or even a little opium, if the diarrhœa be urgent. Where the child is very weak, and the aphthæ of a dark colour, the decoction of bark or other tonics must be had recourse to. The separation of the sloughs and healing of the ulcers may be promoted by washing the mouth occasionally with the honey of borax, diluted with two or three parts of rose water; or where they are of a dark colour, by the decoction of bark, acidulated with sulphuric acid. The diet should be light and nutritious, especially where there is much debility. As the complaint is subsiding, particular attention is required to obviate the bowels becoming confined. In the chronic aphthæ affecting grown persons, pretty much the same plan of treatment is to be pursued: besides which, the compound powder of ipecacuanha and other diaphoretics, assisted by the occasional use of the warm bath, wearing flannel next the skin, particularly in a damp cold climate, &c. appear to be beneficial.

APHYLLUS. (From α, priv. and φυλλον, a leaf.) Leafless. A term applied to parts of plants which are so conditioned when similar parts of other plants have leaves. Thus a stem is said to be aphyllous when it is altogether void of leaves. Linnæus uses the term *nudus*. Examples are found in *Cuscuta Europæa*, dodder; *Asphodelus fistulosus*, &c.

Aphyllæ plantæ. Aphyllous plants, or plants without leaves. Some plants being entirely devoid of leaves, are naturally arranged under one head, to which this name is given.

A′PIS. The name of a genus of insects in the Linnæan system. The bee.

Apis mellifica. The systematic name of the honey-bee. It was formerly dried and powdered, and thus given internally as a diuretic. It is to the industry of this little animal that we are indebted for honey and wax. See *Mel* and *Cera*. The venom of the bee, according to Fontana, bears a close resemblance to that of the viper. It is contained in a small vesicle, and has a hot acrid taste like that of the scorpion.

A′PIUM. (*Apium, i. n.*; from ηπιος, *Doricè*, απιος, mild: or from *apes*, bees; because they are fond of it.) 1. The name of a genus of plants in the Linnæan system. Class, *Pentandria*; Order, *Digynia*.

2. The pharmacopœial name of the herb smallage. See *Apium graveolens*.

Apium graveolens. The systematic name for the *apium* of the pharmacopœias. *Apium—foliolis caulinis, cuneiformibus, umbellis, sessilibus*, of Linnæus. Small-age. The root, seeds, and fresh plant, are aperient and carminative.

Apium hortense. See *Apium petroselinum*.

Apium petroselinum. The systematic name for the *petroselinum* of the pharmacopœias. *Petroselinum vulgare. Apium hortense.* Common parsley. *Apium—foliis caulinis linearibus, involucellis minutis*, of Linnæus. Both the roots and seeds of this plant were formerly directed by the London College for medicinal use, and the root is still retained in the Edinburgh Pharmacopœia: the former have a sweetish taste, accompanied with a slight warmth or flavour, somewhat resembling that of carrot; the latter are in taste warmer and more aromatic than any other part of the plant, and manifest considerable bitterness. The roots are said to be aperient and diuretic, and have been employed in nephritic pains and obstructions of urine. The seeds possess aromatic and carminative powers, but are seldom prescribed.

APLONÆ. A deep orange-brown mineral, mostly considered to be a variety of the garnet.

APNEU′STIA. (From α, and πνεω, to breathe.) A defect or difficulty of respiration, such as happens in a cold, &c. *Foesius.*

Apnœa′. The same.—*Galen.*

Apocapni′smus. (From απο, and καπνος, smoke.) A fumigation.

Apocalha′rsis. (From απο, and καθαιρω, to purge.) An evacuation of humours. A discharge downwards, and sometimes applied, with little discrimination, to vomiting.

Apocaulize′sis. (From αποκαυλξιω, to break transversely.) A transverse fracture.—*Hippocrates.*

APOCENO′SIS. (From απο, and κενοω, to evacuate.) 1. A flow or evacuation of any humour.

2. The name of an order in the class *Locales* of Cullen, which embraces diseases characterised by a superabundant flux of blood, or other fluid, without pyrexia.

Apo′cope. (From απο, and κοπτω, to cut from.) Abscission, or the removal of a part by cutting it off.

Apo′crisis. (From απο, and κρινω, to secrete from.) A secretion of superabundant humours. —*Hippocrates.*

Apocru′sticon. See *Apocrustinum.*

Apocru′stinum. (From αποκρουω, to repel.) *Apocrusticon.* An astringent or repellent medicine.—*Galen.*

Apocye′sis. (From απο, and κυω, to bring forth.) Parturition, or the bringing forth of a child.—*Galen.*

Apodacry′tica. (From απο, and δακρυ, a tear.) Medicines which, by exciting tears, remove superfluous humours from the eyes, as onions, &c.—*Pliny.*

Apogeu′sis. See *Ageustia.*

Apogeu′stia. See *Ageustia.*

Apoginome′sis. (From απογινομαι, to be absent.) The remission or absence of a disease.—*Hippocrates.*

Apoglauco′sis. (From απο, and γλατκος, sky-coloured; so called because of its bluish appearance.) See *Glaucoma.*

Apo′gonum. (From απο, and γινομαι, to beget.) A living fœtus in the womb.—*Hippocrates.*

Apole′psis. (From απο, and λαμβανω, to take from.) An interception, suppression, or retention of urine, or any other natural evacuation.—*Hippocrates.*

Apolino′sis. (From απο, and λινον, flax.) The method of curing a fistula, according to Ægineta, by the application of raw flax.

Apo′lysis. (From απο, and λυω, to release.) The solution or termination of a disease. The removal of a bandage.—*Erotianus.*

APOMA′GMA. (From απο, and ματτω, to cleanse from.) Any thing used to cleanse and wipe away filth from sores, as sponge, &c.—*Hippocrates.*

Apomathe′ma. (From απο, neg. and μανθανω, to learn.) Hippocrates expresses, by this term, a forgetfulness of all that has been learnt.

Apo′meli. (From απο, from, and μελι, honey.) An oxymel, or decoction, made with honey.

APONEURO′SIS. (From απο, and νευρον, a nerve; from an erroneous supposition of the ancients, that it was formed by the expansion of a nerve.) A tendinous expansion. See *Muscle.*

APO′NIA. (From α, priv. and πονος, pain.) Freedom from paiu.

Aponitro′sis. (From *απο*, and *νιτρον*, nitre.) The sprinkling an ulcer over with nitre.

Apopalle′sis. (From *αποπαλλω*, to throw off hastily.) An abortion, or premature expulsion of a fœtus.—*Hippocrates.*

Apopalsis. See *Apopallesis.*

Apopeda′sis. (From *απο*, and *πηδαω*, to jump from.) A luxation.

APOPHLEGMA′SIA. (From *απο*, and *φλεγμα*, phlegm.) A discharge of phlegm or mucus.

APOPHLEGMA′TIC. (*Apophlegmaticus;* from *απο*, and *φλεγμα*, phlegm.) *Apophlegmatizantia; Apophlegmatizonta.* 1. Medicines which excite the secretion of mucus from the mouth and nose.

2. Masticatories.

3. Errhines.

Apophlegmatizantia. See *Apophlegmatic.*

Apophlegmatizonta. See *Apophlegmatic.*

Apophra′xis. (From *απο*, and *φρασσω*, to interrupt.) A suppression of the menstrual discharge.

Apophtha′rma. (From *απο*, and *φθειρω*, to corrupt.) A medicine to procure abortion.

Apophthe′gma. (From *αποφθεγγομαι*, to speak eloquently.) A short maxim, or axiom; a rule.

Apo′phthora. (From *αποφθειρω*, to be abortive.) An abortion.

Apophy′ades. The ramifications of the veins and arteries.—*Hippocrates.*

Apo′phyas. (From *αποφυω*, to proceed from.) Any thing which grows or adheres to another, as a wart to the finger.

APOPHYLLITE. *Ichthyophthalmite.* Fish-eye stone. A mineral composed of silex, potassa, and water, found in the iron mine of Utoe, in Sweden.

APO′PHYSIS. (From *αποφυω*, to proceed from.) 1. In anatomy, *Appendix; Probole; Ecphysis; Processus; Productio; Projectura; Protuberantia.* A process, projection, or protuberance of a bone beyond a plain surface; as the nasal apophysis of the frontal bone, &c.

2. In botany, this word is applied to a fleshy tubercle under the basis of the capsule or dry fruit adhering to the frondose mosses.

Apople′cta vena. A name formerly applied to the internal jugular vein; so called because in apoplexies it appears full and turgid.—*Bartholin.*

APOPLE′CTIC. (From *αποπληξια*, an apoplexy.) Belonging to an apoplexy.

APOPLE′XY. (*Apoplexy, æ.* f.; from *απο*, and *πλησσω*, to strike or knock down; because persons, when seized with this disease, fall down suddenly.) A sudden abolition, in some degree, of the powers of sense and motion, the patient lying in a sleep-like state; the action of the heart remaining, as well as the respiration, often with a stertorous noise. Cullen arranges it in the class *Neuroses*, and order *Comata:*

1. When it takes place from a congestion of blood, it is termed *Apoplexia sanguinea.*

2. When there is an abundance of serum, as in persons of a cold phlegmatic temperament, *Apoplexia serosa.*

3. If it arise from water in the ventricles of the brain, it is called *Apoplexia hydrocephalica.* See *Hydrocephalus.*

4. If from a wound, *Apoplexia traumatica.*

5. If from poisons, *Apoplexia venenata.*

6. If from the action of suffocating exhalations, *Apoplexia suffocata.*

7. If from passions of the mind, *Apoplexia mentalis.*

8. And when it is joined with catalepsy, *Apoplexia cataleptica.*

Apoplexy makes its attack chiefly at an advanced period of life; and most usually on those who are of a corpulent habit, with a short neck, and large head; and who lead an inactive life, make use of a full diet, or drink to excess. The immediate cause of apoplexy, is a compression of the brain, produced either by an accumulation of blood in the vessels of the head, and distending them to such a degree, as to compress the medullary portion of the brain; or by an effusion of blood from the red vessels, or of serum from the exhalants; which fluids are accumulated in such a quantity as to occasion compression. These states, of overdistension and of effusion, may be brought on by whatever increases the afflux, and impetus of the blood in the arteries of the head; such as violent fits of passion, great exertions of muscular strength, severe exercise, excess in venery, stooping down for any length of time, wearing any thing too tight about the neck, overloading the stomach, long exposure to excessive cold, or a vertical sun, the sudden suppression of any long-accustomed evacuation, the application of the fumes of certain narcotic and metallic substances, such as opium, alcohol, charcoal, mercury, &c. and by blows, wounds, and other external injuries: in short, apoplexy may be produced by whatever determines too great a flow of blood to the brain, or prevents its free return from that organ.

The young, and those of a full plethoric habit, are most liable to attacks of the sanguineous apoplexy; and those of a phlegmatic constitution, or who are much advanced in life, to the serous. Apoplexy is sometimes preceded by headache, giddiness, dimness of sight, loss of memory, faltering of the tongue in speaking, numbness in the extremities, drowsiness, stupor, and night-mare, all denoting an affection of the brain; but it more usually happens that, without much previous indisposition, the person falls down suddenly, the countenance becomes florid, the face appears swelled and puffed up, the vessels of the head, particularly of the neck and temples, seem turgid and distended with blood; the eyes are prominent and fixed, the breathing is difficult and performed with a snorting noise, and the pulse is strong and full. Although the whole body is affected with the loss of sense and motion, it nevertheless takes place often more upon one side than the other, which is called hemiplegia, and in this case, the side least affected with palsy is somewhat convulsed.

In forming an opinion as to the event, we must be guided by the violence of the symptoms. If the fit is of long duration, the respiration laborious and stertorous, and the person much advanced in years, the disease, in all probability, will terminate fatally. In some cases, it goes off entirely; but it more frequently leaves a state of mental imbecility behind it, or terminates in a hemiplegia, or in death. Even when an attack is recovered from, it most frequently returns again, after a short period of time, and in the end proves fatal. In dissections of apoplexy, blood is often found effused on the surface and in the cavities of the brain; and in other instances, a turgidity and distention of the blood-vessels are to be observed. In some cases, tumours have been found attached to different parts of the substance of the brain, and in others, no traces of any real affection of it could be observed.

On an attack of sanguineous apoplexy, all compression should be removed from the neck, the patient laid with his head a good deal raised, and a free admission of cool air allowed. Then blood should be taken freely from the arm or the temporal artery, or the jugular vein; which it may be sometimes necessary to repeat, if the symptoms continue, and the patient is still plethoric; or if blood can less be spared, cupping or leeches may lessen the congestion in the brain. The next object should be thoroughly to evacuate the bowels by some active purgative, as calomel joined with jalap, or with extract of colocynth, or followed by infusion of senna and some neutral salt, with a little tartarized antimony or tincture of jalap repeated every two hours till it operates; or a draught of tincture of senna and wine of aloes, where the bowels are very torpid, may answer the purpose. Stimulant glysters will also be proper, particularly if the patient cannot swallow, as common salt and syrup of buckthorn, with a proper quantity of gruel, infusion of senna or infusion of colocynth; or a turpentine glyster in elderly torpid habits. Cold should then be applied assiduously to the scalp, the hair being previously shaved, and a blister to the back of the neck; and diaphoretic medicines may be exhibited, avoiding, however, those which contain opium. Sinapisms to the feet may also be useful, particularly if these are cold. If under these means, the sensibility does not gradually return, some of the gentle diffusible stimulants will be proper, as ammonia, mustard, ether, camphor, &c.: and at this period, a blister to the scalp may come in aid. By some practitioners emetics are recommended, but their use is hazardous, especially if sufficient evacuations be not premised: and the same may be observed of sternutatories. In the serous form of the disease, general bleeding is inadmissible, and even the local abstraction of blood should be very sparingly made; the bowels should be kept open, especially by aloetic or mercurial formulæ, but not procuring profuse discharges; and the other secretions maintained, especially by the use of the diffusible stimulants already mentioned; blisters to the head, and errhines may be here also useful. When apoplectic symptoms have been occasioned by opium, or other narcotics, the timely discharge of this by an active emetic will be the most important measure; but in a plethoric habit, bleeding should be premised; subsequently various stimulants may be employed, as ammonia, vinegar, &c. endeavouring to procure a determination to the surface, and rousing the patient from his torpid state. The prevention of the sanguineous form of the disease will be best attempted by abstemiousness, regular moderate exercise, and keeping up the evacuations; an issue or seton may also be useful; but under urgent circumstances, bleeding, especially topical, must be resorted to. In leucophlegmatic habits, a more nutritious diet will be proper.

APOPNI′XIS. (From αποπνιγω, to suffocate.) A suffocation.—*Moschion.*

APOPSOPHE′SIS. (From απο, and ψοφεω, to emit wind.) The emission of wind by the anus or uterus, according to Hippocrates.

APOPSY′CHIA. (From απὸ, from, and ψυχη, the mind.) The highest degree of deliquium, or fainting, according to Galen.

APO′PTOSIS. (From αποπιπτω, to fall down.) A prolapsus, or falling down of any part through relaxation.—*Erotian.*

Apore′xis. (From απο, and ορεγω, to stretch out.) A play with balls, in the gymnastic exercises.

Apo′ria. (From α, priv. and πορος, a duct.) Restlessness, uneasiness, occasioned by the interruption of perspiration, or any stoppage of the natural secretions.

Aporrhi′psis. (From αποῤῥιπτω, to cast off.) Hippocrates used this word to signify that kind of insanity where the patient tears off his clothes, and casts them from him.

Aposceparni′smus. (From απο, from, and σκεπαρνιζω, to strike with a hatchet.) *Deasciatio.* A species of fracture, when part of a bone is chipped off.—*Gorræus.*

Aposcha′sis. (From απο, and σχαζω, to scarify.) *Aposchasmus.* A scarification. Venesection.—*Hippocrates.*

Aposi′tia. (From ἀπο, from, and σιτος, food) *Apositios.* A loathing of food.—*Galen.*

Apospa′sma. (From αποσπαω, to tear off.) A violent, irregular fracture of a tendon, ligament, &c.—*Galen.*

Aposphaceli′sis. (From απο, and σφακελος, a mortification.) Hippocrates uses this word to denote a mortification of the flesh in wounds, or fractures, caused by too tight a bandage.

APO′STASIS. (From απο, and ιϛημι, to recede from.) 1. An abscess, or collection of matter.

2. The coming away of a fragment of bone, by fracture.

3. When a distemper passes away by some outlet, Hippocrates calls it an *apostasis by excretion.*

4. When the morbific matter, by its own weight, falls and settles on any part, an *apostasis by settlement.*

5. When one disease turns to another, an *apostasis by metastasis.*

APOSTA′XIS. (From αποϛαζω, to distil from.) Hippocrates uses this word to express the defluxion or distillation of any humour, or fluid: as blood from the nose.

APOSTELUS. An apostle. An ointment and other things were formerly so designated from some famous inventer; as unguentum apostelorum, because it has twelve ingredients in it.

APOSTEMA. (*Apostema, atis.* n.; from αφιϛημι, to recede.) The term given by the ancients to abscesses in general. See *Abscess.*

APOSTEMA′TIAI. Those who, from an inward abscess, void pus downwards, are thus called by Aretæus.

Aposteri′gma. (From αποϛηριγω, *fulcio.*) Galen uses this word to denote a rest of a diseased part, a cushion.

Apo′strophe. (From απο, and ϛρεφω, to turn from.) Thus Paulus Ægineta expresses an aversion for food.

APOSYRINGE′SIS. (From απο, and συριγξ, a fistula.) The degeneracy of a sore into a fistula.—*Hippocrates.*

APOSY′RMA. (From απο, and συρω, to rub off.) An abrasion or disquamation of the bones or skin.—*Hippocrates.*

APOTANEUSIS. (From απο, and τεινω, to extend.) An extension, or elongation, of any member or substance.

Apotelme′sis. (From απο, and τελμα, a bog.) An expurgation of filth, or fæces.

APOTHE′CA. (Αποθηκη; from αποτιθημι, to reposit.) A shop, or vessel, where medicines are sold, or deposited.

APOTHECA′RY. (*Apothecarius*; from απο, and τιθημι, *pono,* to put: so called from his employ being to prepare, and keep in readiness, the various articles in the *Materia Medica,* and to compound them for the physician's use; or from αποθήκη, a shop.) In every European country, except Great Britain, the *apothecary* is the same as we name in England the *druggist* and *chemist.*

APOTHERAPEI'A. (From *απο*, and *θεραπευω*, to cure.) A perfect cure, according to Hippocrates.

Apotherapeu'tica. (From *αποθεραπευω*, to heal.) Therapeutics. That part of medicine which teaches the art of curing disorders.

Apothe'rmum. (From *απο*, and *θερμη*, heat.) An acrimonious pickle, with mustard, vinegar, and oil.—*Galen*.

APO'THESIS. (From *απο*, and *τιθημι*, to replace.) The reduction of a dislocated bone, according to Hippocrates.

APO'THLI'MMA. (From *απο*, and *θλιβω*, to press from.) The dregs or expressed juice of a plant.

Apothrau'sis. (From *απο*, and *θραυω*, to break.) The taking away the splinters of a broken bone.

Apo'tocus. (From *απο*, and *τικτω*, to bring forth.) Abortive; premature.—*Hippocrates*.

Apotre'psis. (From *απο*, and *τρεπω*, to turn from.) A resolution or reversion of a suppurating tumour.

Apotropæ'a. (From *αποτρεπω*, to avert.) An amulet, or charm, to avert diseases.—*Foësius*.

A'POZEM. (*Apozema*. From *απο*, and *ζεω*, to boil.) A decoction.

Apozeu'xis. (From *απο*, and *ζευγνυμι*, to separate.) The separation or removal of morbid parts.—*Hippocrates*.

Apo'zymos. (From *απο*, and *ζυμη*, ferment.) Fermented.

APPARA'TUS. (From *appareo*, to appear, or be ready at hand.) This term is applied to the instruments and the preparation and arrangement of every thing necessary in the performance of any operation, medical, surgical, or chemical.

Apparatus altus. See *Lithotomy*.

Apparatus major. See *Lithotomy*.

Apparatus minor. See *Lithotomy*.

Apparatus, pneumatic. The discovery of aëriform fluids has, in modern chemistry, occasioned the necessity of some peculiar instruments, by means of which those substances may, in distillations, solutions, or other operations, be caught, collected, and properly managed. The proper instruments for this are styled the pneumatic apparatus. Any kind of air is specifically lighter than any liquid; and, therefore, if not decomposed by it, rises through it in bubbles. On this principle rests the essential part of the apparatus, adapted to such operations. Its principal part is the pneumatic trough, which is a kind of reservoir for the liquid, through which the gas is conveyed and caused to rise, and is filled either with water or with quicksilver. Some inches below its brim an horizontal shelf is fastened, in dimension about half or the third part of the trough, and in the water-trough this is provided on its foremost edge with a row of holes, into which, from underneath, short-necked funnels are fixed. The trough is filled with water sufficient to cover the shelf, to support the receivers, which being previously filled with water are placed invertedly, their open end turned down upon the above-mentioned holes, through which afterwards the gases, conveyed there and directed by means of the funnels, rise in the form of air bubbles.

In some cases the trough must be filled with quicksilver, because water absorbs or decomposes some kinds of air. The price and specific gravity of that metal make it necessary to give to the quicksilver trough smaller dimensions. It is either cut in marble, or made of wood well joined. The late Karston has contrived an apparatus, which, to the advantage of saving room, adds that of great conveniency.

To disengage gases, retorts of glass, either common or tubulated, are employed, and placed in a sand-bath, or heated by a lamp. Earthen, or coated glass retorts, are put in the naked fire. If necessary, they are joined with a metallic or glass conveying pipe. When, besides the aëriform, other fluids are to be collected, the middle or intermediate bottle finds its use; and to prevent, after cooling, the rising of the water from the trough into the disengaging vessel, the tube of safety is employed. For the extrication of gases taking place in solutions, for which no external heat is required, the bottle called disengaging bottle, or proof, may be used. For receivers, to collect disengaged airs, various cylinders of glass are used, whether graduated or not, either closed at one end or open at both; and in this last case, they are made air-tight by a stopper fitted by grinding. Besides these, glass bells and common bottles are employed.

To combine with water, in a commodious way, some gases that are only gradually and slowly absorbed by it, the glass apparatus of Parker is serviceable.

APPENDI'CULA. A little appendage.

Appendicula cæci vermiformis. A vermicular process, about four inches in length, and the size of a goose-quill, which hangs to the intestinum cæcum of the human body.

Appendiculæ epiploicæ. *Appendices coli adiposæ*. The small appendices of the colon and rectum, which are filled with adipose substance. See *Omentum*.

APPENDICULA'TUS. Applied to leaves, leaf-stalks, &c. that are furnished with an additional organ for some particular purpose not essential to it; as the *Dionæa muscipula*, the leaves of which terminate each in a pair of toothed irritable lobes, that close over and imprison insects; as also the leaf of the *Nepentha distillatorea*, which bears a covered pitcher full of water; the leaves of our *Utriculum*, which have numerous bladders attached to them which seem to secrete air and float them; and the petiolus of the *Dipsacus pilosus*, which has little leaves at its base.

APPENDIX. 1. An appendage; that which belongeth to any thing.

2. See *Apophysis*.

APPLE. See *Pyrus*.

Apple, acid of. See *Malic acid*.

Apple, pine. See *Bromelia ananus*.

Apple, thorn. See *Datura stramonium*.

Appropriate affinity. See *Affinity intermediate*.

APRICOT. See *Prunus armeniaca*.

APYRE'XIA. (From *α*, priv. and *πυρεξια*, a fever.) Apyrexy. Without fever. The intermission of feverish heat.

APYRI'NUS. (From *α*, priv. and *πυρην*, *nucleus*, a kernel.) Without a kernel.

Apyrinæ plantæ. Plants without kernels. The name in Gerard's arrangement of a class of plants.

APYROUS. Bodies which sustain the action of a strong heat for a considerable time, without change of figure or other properties, have been called apyrous; but the word is now very seldom used. It is synonymous with *refractory*.

A'QUA. See *Water*.

Aquæ aeris fixi. Water impregnated with fixed air. This is liquid carbonic acid, or water impregnated with carbonic acid. It sparkles in the glass, has a pleasant acidulous taste, and forms an excellent beverage. It diminishes thirst, lessens the morbid heat of the body, and acts as a powerful diuretic. It is also an excellent remedy in increasing irritability of the stomach, as in advanced pregnancy, and it is one of the best anti-emetics which we possess.

AQUA ALUMINIS COMPOSITA. Compound solution of alum, formerly called aqua aluminosa bateana. See *Liquor aluminis compositus.*

AQUA AMMONIÆ ACETATÆ. See *Ammoniæ acetatis liquor.*

AQUA AMMONIÆ PURÆ. See *Ammonia.*

AQUA ANETHI. See *Anethum graveolens.*

AQUA CALCIS. See *Calcis liquor.*

AQUA CARUI. See *Carum carui.*

AQUA CINNAMOMI. See *Laurus cinnamomum.*

AQUA CŒLESTIS. A preparation of copper.

AQUA CUPRI AMMONIATI. See *Cupri ammoniati liquor.*

AQUA CUPRI VITRIOLATI COMPOSITA. This preparation of the Edinburgh Pharmacopœia, is used externally, to stop hæmorrhages of the nose, and other parts. It is made thus: ℞ *Cupri vitriolati, Aluminis, sing.* ℥ss. *Aquæ puræ,* ℥iv. *Acidi vitriolici,* ʒij. Boil the salts in water until they are dissolved; then filter the liquor, and add the acid.

AQUA DISTILLATA. Distilled water. This is made by distilling water in clean vessels, until about two-thirds have come over. In nature, no water is found perfectly pure. Spring or river water always contains a portion of saline matter, principally sulphate of lime; and, from this impregnation, is unfit for a number of pharmaceutic preparations. By distillation, a perfectly pure water is obtained. The London College directs ten gallons of common water; of which, first distil four pints, which are to be thrown away; then distil four gallons. This distilled water is to be kept in glass vessels. See *Water.*

AQUA FŒNICULI. See *Anethum fœniculum.*

AQUA FORTIS. This name is given to a weak and impure nitric acid, commonly used in the arts. It is distinguished by the terms *double* and *single,* the single being only half the strength of the other. The artists who use these acids call the more concentrated acid, which is much stronger even than the double aqua fortis, *spirit of nitre.* This distinction appears to be of some utility, and is therefore not improperly retained by chemical writers. See *Nitric acid.*

AQUA KALI PRÆPARATI. See *Potassæ subcarbonatis liquor.*

AQUA KALI PURI. See *Potassæ liquor.*

AQUA LITHARGYRI ACETATI. See *Plumbi acetatis liquor.*

AQUA LITHARGYRI ACETATI COMPOSITA. See *Plumbi acetatis liquor dilutus.*

AQUA MARINE. See *Beryl.*

AQUA MENTHÆ PIPERITÆ. See *Mentha piperita.*

AQUA MENTHÆ SATIVÆ. See *Mentha viridis.*

AQUA MENTHÆ VIRIDIS. See *Mentha viridis.*

AQUA DE NAPOLI. See *Aquetta.*

AQUA PIMENTÆ. See *Myrtus pimenta.*

AQUA PULEGII. See *Mentha Pulegium.*

AQUA REGIA. *Aqua regalis.* This acid, which is a mixture of the nitric and muriatic acids, lately called nitro-muriatic, and now chlorine, was formerly called aqua regalis, because it was, at that time, the only acid that was known to be able to dissolve gold. See *Chlorine.*

AQUA ROSÆ. See *Rosa centifolia.*

AQUA STYPTICA. A name formerly given to a combination of powerful astringents, viz. sulphate of copper, sulphate of alum, and sulphuric acid. It has been applied topically to check hæmorrhage, and, largely diluted with water, as a wash in purulent ophthalmia. See *Aqua cupri vitriolati composita.*

Aqua Toffania. See *Aquetta.*

AQUA VITÆ. Ardent spirit of the first distillation has been distinguished in commerce by this name.

AQUA ZINCI VITRIOLATI CUM CAMPHORA. *Aqua vitriolica camphorata.* This is made by dissolving half an ounce of sulphate of zinc in a quart of boiling water, adding half an ounce of camphorated spirit, and filtering. This, when properly diluted is an useful collyrium for inflammations of the eyes, in which there is a weakness of the parts. Externally, it is applied by surgeons to scorbutic and phagedenic ulcerations.

AQUÆ DISTILLATÆ. Distilled waters. These are made by introducing vegetables, as mint, penny-royal, &c. into a still with water; and drawing off as much as is found to possess the properties of the plants. The London College orders the waters to be distilled from dried herbs, because fresh are not ready at all times of the year. Whenever the fresh are used, the weights are to be increased. But wheher the fresh or dried herbs are employed, the operator may vary the weight according to the season in which they have been produced and collected. Herbs and seeds, kept beyond the space of a year, are improper for the distillation of waters. To every gallon of these waters, five ounces, by measure, of proof spirit are to be added.

AQUÆ MINERALES. See *Mineral waters.*

AQUÆ STILLATITIÆ SIMPLICES. Simple distilled waters.

AQUÆ STILLATITIÆ SPIRITUOSÆ. Spirituous distilled waters, now called only spiritus; as spiritus pulegii.

AQUÆDUCT. *Aquæductus;* a canal or duct so named because it was supposed to carry a watery fluid.

AQUÆDUCT OF FALLOPIUS. A canal in the petrous portion of the temporal bone, first accurately described by Fallopius.

Aquatic nut. See *Trapa natans.*

AQUATICÆ PLANTÆ. Aquatic plants, or such as grow in or near water. A natural order of plants.

AQUATICUS. (From *aqua,* water.) Aquatic; or belonging to the water.

AQUEOUS. (*Aquosus,* watery.) Of the nature of, or resembling water.

AQUEOUS HUMOUR. *Humor Aquosus.* The very limpid watery fluid, which fills both chambers of the eye. See *Eye.*

AQUE'TTA. The name of a liquid poison, made use of by the Roman women, under the Pontificate of Alexander VII. It was prepared, and sold in drops, by Tophania, or Toffania, an infamous woman who resided at Palermo, and afterwards at Naples. From her, these drops obtained the name of *Aqua Toffania; Aqua della Toffana;* and also *Aqua di Napoli.* This poison is said by some to be a composition of arsenic, and by others of opium and cantharides.

AQUIFO'LIUM. (From *acus,* a needle, and *folium,* a leaf; so called on account of its prickly leaf.) See *Ilex aquifolium.*

A'QUILA. (Αετος, the eagle.) 1. A species of the extensive genus *Falco* of ornithologists.

2. Aquila, among the ancients, had many other epithets joined with it, as rubra, salutifera, volans, &c.

3. A chemical name formerly used for sal-am-

moniac, mercurius præcipitatus, arsenic, sulphur, and the philosopher's stone.

Aquila alba. One of the names given to calomel by the ancients. See *Hydrargyri. submurias.*

Aquila alba philosophorum. *Aqua alba ganymedis.* Sublimed sal-ammoniac.

Aquila cœlestis. A panacea, or cure for all diseases; a preparation of mercury.

Aquila veneris. A preparation of the ancients, made with verdigris and sublimed sal-ammoniac.

Aquilæ lignum. Eagle-wood. It is generally sold for the agallochum. See *Lignum aloes.*

Aquilæ venæ. Branches of the jugular veins, which are particularly prominent in the eagle.

AQUILE'GIA. (From *aqua*, water, and *lego*, to gather; so called from the shape of its leaves, which retain water.) The herb columbine.

1. The name of a genus of plants in the Linnæan system. Class, *Polyandria;* Order, *Pentagynia.*

2. The name in the pharmacopœias, for the columbine. See *Aquilegia vulgaris.*

Aquilegia vulgaris. The systematic name of the columbine. The seeds, flowers, and the whole plant, have been used medicinally, the first in exanthematous diseases, the latter chiefly as an antiscorbutic. Though retained in several foreign pharmacopœias, their utility seems to be not allowed in this country.

Aquili'na. (From *Aquila*, an eagle; so called from the resemblance of its leaves to eagle's wings.) The trivial name of a species of pteris. See *Pteris.*

AQUU'LA. (Diminutive of *aqua.*) A small quantity of very fine and limpid water. This term is applied to the pellucid water, which distends the capsule of the crystalline lens, and the lens itself. Paulus Ægineta uses it to denote a tumour consisting of a fatty substance under the skin of the eyelid.

Arabic gum. See *Acaciæ gummi.*

A'racalan. An amulet.

A'raca miri. (Indian.) A shrub growing in the Brazils, the roots of which are diuretic and antidysenteric.

ARA'CHNE. (From *arag*, Hebrew, to weave; or from *αραχνη*, a spider.) The spider.

ARACHNOID. (*Arachnoides;* from *αραχνη*, a spider, and *ειδος*, likeness; so named from its resemblance to a spider's web.) Web-like.

Arachnoid membrane. *Membrana arachnoides.* 1. A thin membrane of the brain, without vessels and nerves, situated between the dura and pia mater, and surrounding the cerebrum, cerebellum, medulla oblongata, and medulla spinalis.

2. The term is also applied by some writers to the tunic of the crystalline lens and vitreous humour of the eye.

ARACK. (Indian.) An Indian spirituous liquor, prepared in many ways, often from rice; sometimes from sugar, fermented with the juice of cocoa-nuts; frequently from toddy, the juice which flows from the cocoa-nut tree by incision, and from other substances.

A'rados. (From *αραδεω*, to be turbulent.) Hippocrates uses this term to signify a commotion in the stomach, occasioned by the fermentation of its contents.

Aræo'tica. (From *αραιοω*, to rarefy.) Things which rarefy the fluids of the body.

ARA'LIA. (From *ara*, a bank in the sea; so called because it grows upon banks near the sea.) The name of a genus of plants in the Linnæan system. Class, *Pentandria;* Order, *Pentagynia.* The berry-bearing angelica. Of the several species of this tree, the roots of the nudicaulis, or naked-stalked, were brought over from North America, where it grows, and sold here for sarsaparilla.

Ara'nea. (From *αραω*, to knit together.)

1. The name of a genus of insects.

2. The spider.

ARA'NTIUS, Ju'lius Cæsar, a celebrated anatomist and physician, born at Bologna, about the year 1530. After studying under Vesalius, and others, he graduated and became professor there, and died in 1589. In his first work, "On the Human Fœtus," he described the foramen ovale, and ductus arteriosus, and corrected several errors in the anatomy of the gravid uterus, which had been generally derived from the examination of brutes. He afterwards showed that the blood, after birth, could only pass from the right to the left side by the heart through the vessels of the lungs, thus preparing for the discovery of the circulation of Harvey. A Treatise on Tumours, and a Commentary on part of Hippocrates, were also written by him.

ARA'TRUM. The plough. A plant has this for a trivial name, because its roots are found to hinder the plough: hence *remora aratri.* See *Ononis spinosa.*

ARBOR. A tree. 1. In botany, a plant, consisting of one trunk which rises to a great height, is very durable, woody, and divided at its top into branches which do not perish in the winter; as the oak, elm, ash, &c.

2. In anatomy, it is applied to parts which ramify like a tree; as the *Arbor vitæ* of the cerebellum.

3. In chemistry, applied to crystallisations which ramify like branches.

Arbor dianæ. See *Silver.*

Arbor vitæ. The tree of life.

1. The cortical substance of the cerebellum is so disposed, that, when cut transversely, it appears ramified like a tree, from which circumstance it is termed *arbor vitæ.*

2. The name of a tree formerly in high estimation in medicine. See *Thuya occidentalis.*

Arbores. One of the natural divisions or families of plants. Trees consist of a single and durable woody trunk, bearing branches, which do not perish in the winter, as *Tilia, Fraxinus, Pyrus,* &c.

ARBUSTIVA. (From *arbustum*, a copse of shrubs or trees.) The name of an order of plants in Linnæus's natural method.

ARBUTHNOT, John, a physician, born in Scotland soon after the restoration, celebrated for his wit and learning. He graduated at Aberdeen, and settling in this metropolis, had the good fortune to be at Epsom, when Prince George of Denmark was taken ill there; whom, having restored to health, he was appointed physician to Queen Anne, but never got into very extensive practice. His chief medical publications were "On the Choice of Aliments," and "On the Effects of Air upon Human Bodies." He died in 1735.

A'RBUTUS. The name of a genus of plants in the Linnæan system. Class, *Decandria;* Order, *Monogynia.*

Arbutus, trailing. See *Arbutus uva ursi.*

Arbutus unedo. *Amatzquitl; Unedo papyracea.* A decoction of the bark of the root of this plant is commended in fevers.

Arbutus uva ursi. The systematic name for the officinal trailing Arbutus; Bear's berry;

Bear's whortle-berry; Bear's whorts; or Bear's bilberries; called also *Vaccaria*. *Arbutus—caulibus procumbentibus, foliis integerrimis*, of Linnæus. This plant, though employed by the ancients in several diseases, requiring adstringent medicines, had almost entirely fallen into disuse until the middle of the present century, when it first drew the attention of physicians, as a useful remedy in calculous and nephritic complaints, which diseases it appears to relieve by its adstringent qualities.

A′RCA ARCANORUM. The mercury of the philosophers.

A′RCA CORDIS. The pericardium.

ARCA′NUM. A secret. A medicine, the preparation or efficacy of which is kept from the world, to enhance its value. With the chemists, it is a thing secret and incorporeal; it can only be known by experience, for it is the virtue of every thing, which operates a thousand times more than the thing itself.

ARCANUM CATHOLICUM. Bezoar, plantain, and colchicum.

ARCANUM DUPLEX. *Arcanum duplicatum.* A name formerly given to the combination of potassa and sulphuric acid, more commonly called vitriolated tartar, and now sulphate of potassa.

ARCANUM TARTARI. The acetate of potassa.

ARCE′RTHOS. Juniper.

ARCHÆ′US. 1. The universal archæus, or principle of Van Helmont, was the active principle of the material world. See *Vis vitæ*.

2. Good health.

A′RCHE. (From αρχη, the beginning.) The earliest stage of a disease.

ARCHE′NDA. (Arabian.) A powder made of the leaves of the ligustrum, to check the fœtid odour of the feet.

ARCHEO′STIS. White briony.

Archil. See *Lichen rocella*.

Archilla. See *Lichen rocella*.

ARCHIMA′GIA. (From αρχη, the chief, and *magaa*, the Arabian for meditation.) Chemistry, as being the chief of sciences.

ARCHI′THOLUS. (From αρχη, the chief, and ϑολος, a chamber.) The sudatorium, or principal room of the ancient baths.

ARCHOPTO′MA. (From αρχος, the anus, and πιπτω, to fall down.) A bearing down of the rectum, or prolapsus ani.

A′RCHOS. (From αρχος, an arch.) The anus; so called from its shape.

ARCTA′TIO. (From *arcto*, to make narrow.) *Arctitudo.* Narrowness.

1. A constipation of the intestines, from inflammation.

2. A preternatural straitness of the pudendum muliebre.

A′RCTIUM. (From αρκτος, a bear; so called from its roughness.) The name of a genus of plants in the Linnæan system. Class, *Syngenesia*; Order, *Polygamia æqualis*. The burdock.

ARCTIUM LAPPA. The systematic name for the herb clot bur, or burdock. *Bardana; Arctium; Britannica; Ilaphis.* The plant so called in the pharmacopœias, is the *Arctium—foliis cordatis, inermibus, petiolatis*, of Linnæus. It grows wild in uncultivated grounds. The seeds have a bitterish subacrid taste: they are recommended as very efficacious diuretics, given either in the form of emulsion, or in powder, to the quantity of a drachm. The roots taste sweetish, with a slight austerity and bitterness: they are esteemed aperient, diuretic, and sudorific; and are said to act without irritation, so as to be safely ventured upon in acute disorders. Decoctions of them have been used, in rheumatic, gouty, venereal, and other disorders; and are preferred by some to those of sarsaparilla. Two ounces of the roots are to be boiled in three pints of water, to a quart; to this, two drachms of sulphate of potassa have been usually added. Of this decoction, a pint should be taken every day in scorbutic and rheumatic cases, and when intended as a diuretic, in a shorter period.

ARCTIZITE. The foliated species of scapolite. See *Scapolite*.

ARCTU′RA. (From *arcto*, to straiten.) An inflammation of the finger, or toe, from a curvature of the nail.—*Linnæus.*

ARCUA′LIA. (From *arcus*, a bow.) *Arcualis.* The sutura coronalis is so named, from its bow-like shape; and, for the same reason, the bones of the sinciput are called *arcualia ossa.*—*Bartholin.*

ARCUA′TIO. (From *arcus*, a bow.) A gibbosity of the fore-parts, with a curvation of the sternum, of the tibia, or dorsal vertebræ.—*Avicenna.*

A′RCULÆ. (A dim. of *arca*, a chest.) The orbits or sockets of the eyes.

A′RDAS. (From αρδυω, to defile.) Filth, excrement, or refuse.—*Hippocrates.*

ARDENT. (*Ardens*; from *ardeo*, to burn.) Burning hot. Applied to fevers, alkohol, &c.

ARDOR. (*Ardor, oris.* m.; from *ardeo*, to burn.) A burning heat.

ARDOR FEBRILIS. Feverish heat.

ARDOR URINÆ. Scalding of the urine, or a sense of heat in the urethra.

ARDOR VENTRICULI. Heartburn.

A′REA. 1. An empty space.

2. That kind of baldness where the crown of the head is left naked, like the tonsure of a monk.

ARE′CA. The name of a genus of plants, of the class *Palmæ*.

ARECA INDICA. An inferior kind of nutmeg.

ARE′GON. (From αρηγω, to help; so called from its valuable qualities.) A resolvent ointment.

AREMA′ROS. Cinnabar.

ARE′NA. Sand, or gravel.

ARENA′MEL. (From *arena*, sand; so called because it was said to be procured from sandy places.) *Arenamen.* Bole-armenic.

ARENA′TIO. (From *arena*, sand.) Saburation, or the sprinkling of hot sand upon the bodies of patients.—*Baccius de Thermis.*

ARENDATE. See *Epidote*.

ARE′NTES. (From *areo*, to dry up.) A sort of ancient cupping-glasses, used without scarifying.

ARE′OLA. (A diminutive of *area*, a void space.) A small red or brown circle, which surrounds the nipples of females. During and after pregnancy, it becomes considerably larger.

AREOMETER. See *Hydrometer*.

ARETÆNOI′DES. See *Arytænoides*.

ARETÆ′US, of Cappadocia, a physician, who practised at Rome, but at what period is uncertain, though the most probable opinion places him between the reigns of Vespasian and Adrian. Eight books of his remain "On the Causes, Signs, and Method of treating acute and chronic Diseases," written in the Greek language, and admired for their pure style, and luminous descriptions, as well as the judicious practice generally recommended. He was partial to the use of hellebore and other drastic medicines; and appears to have been among the first to recommend cantharides for blistering the skin.

A′RETE. (Αρετη, virtue.) Hippocrates uses this word to mean corporeal or mental vigour.

ARE′US. A pessary, invented by Ægineta.

A′RFAR. *Arsag.* Arsenic.—*Ruland, &c.*

A′RGAL. Argol. Crude tartar, in the state in which it is taken from the inside of wine-vessels, is known in the shops by this name.

ARGASY′LLIS. (From *αργος*, a serpent; which it is said to resemble.) The plant which was supposed to produce gum-ammoniac. See *Heracleum gummiferum.*

A′RGEMA. (From *αργος*, white.) *Argemon.* A small white ulcer of the globe of the eye.—*Erotianus. Galen, &c.*

Argentate of ammonia. Fulminating silver.

ARGENTI NITRAS. *Argentum nitratum; Causticum lunare.* Nitrate of silver. Take of silver an ounce; nitric acid, a fluid ounce; distilled water, two fluid ounces. Mix the nitric acid and water, and dissolve the silver therein on a sand bath; then increase the heat gradually that the nitrate of silver may be dried. Melt the salt in a crucible over a slow fire until the water being evaporated, it shall cease to boil; then pour it quickly into moulds of convenient shape. Its virtues are corrosive and astringent. Internally it is exhibited in very small quantities, in epilepsy, chorea, and other nervous affections, and externally it is employed to destroy fungous excrescences, callous ulcers, fistulas, &c. In the latter disease it is used as an injection; from two grains to three being dissolved in an ounce of distilled water.

ARGE′NTUM. (*Argentum, i. m.*; from *αργος*, white, because it is of a white colour.) Silver. See *Silver.*

ARGENTUM FUSUM. Crude mercury.

ARGENTUM MOBILE. Crude mercury.

ARGENTUM NITRATUM. See *Argenti nitras.*

ARGENTUM VIVUM. See *Mercury.*

A′RGES. (From *αργὸς*, white.) A serpent, with a whitish skin, deemed by Hippocrates exceedingly venomous.

ARGI′LLA. (*Argilla, æ. f.*; from *αργος*, white.) Argil. White clay; See *Alumina.*

ARGILLA VITRIOLATA. Alum.

ARGILLACEOUS. Of or belonging to argilla, or aluminous earth. See *Alumina.*

Argillaceous earth. See *Alumina.*

Argillaceous schistus. See *Clay-slate.*

ARGILLITE. See *Clay-slate.*

ARGYRI′TIS. (From *αργυρος*, silver.) Litharge, or spume of silver. A kind of earth was formerly so named, which is taken from silver mines, and is bespangled with many particles of silver.

ARGYRO′COME. (From *αργυρος*, silver, and *κόμη*, hair.) A species of *gnaphalium* or cudweed was so named from its white silvery floscules.

ARGYROLI′BANOS. The white olibanum.

ARGYRO′PHORA. An antidote, in the composition of which there is silver.

ARGYROTROPHE′MA. (From *αργος*, white, and *τροφημα*, food,) A white cooling food, made with milk. Milk diet.—*Galen.*

ARHEUMATI′STOS. (From *α*, neg. and *ῥευματιζω*, to be afflicted with rheums.) Not being afflicted with gouty rheums.

ARICY′MON. (From *αρι* and *κυω*, to be quickly impregnated.) A woman who conceives quickly and often.

ARILLUS. (From *arère*, to be dry or parched.) The seed-coat or tunic of the permanent husk that invests a seed, which drying falls off spontaneously. It is a peculiar membrane, thick, and loosely surrounds the seed.

The varieties of arilli are,

1. The *succulent*, pulpy; like a berry in *Evonymus europeus* and *Lætia.*

2. *Cartilaginous*; in *Coffea Arabica.*

3. *Dimidiate*, half round; as in *Taxus baccata.*

4. *Lacerate*, cut-like; as in the mace of the *Myristica moschata.*

5. *Reticulate*, net-like, surrounding the seed like a net; as in the *Orchis* tribe.

6. *Tricuspid*; as in *Malva coromandiliana.*

7. *Hirsute*, hairy; as in *Geranium incanum.*

8. *Villous*; in *Geranium dissectum.*

ARISTA. (From *areo*, to dry.) The awn; a sharp beard, or point, or bristle-like filament, which proceeds from the husk or glume of grasses. Its distinctions are into,

1. *Naked*, without villi; as in *Stipa arguens* and *juncea.*

2. *Plumose*, having white villi; as in *Stipa pennata.*

3. *Straight*, as in *Bromus secalinus*, and *mollis.*

4. *Geniculate*, having a knee-like bend; as with *Avena sativa.*

5. *Recurved*, bent back; as in *Holcus lanatus*, and *Agrostis canina.*

6. *Tortile*, twisted like a rope; as in *Agrostis rubra*, and *Aira montana.*

7. *Terminal*, fixed to the apex of the husk: it is so in *Agrostis miliacea.*

8. *Dorsal*, fixed to the back or outward part of the husk; as in *Agrostis canina; Bromus; Alopecuris.*

9. *Uncinate*, hooked; as in *Panicum hirtellum.*

ARISTALTHÆ′A. (From *αριςος*, best, and *αλθαια*, the althæa.) The common marsh-mallow. See *Althæa officinalis.*

ARISTATUS. (From *arista*, the awn.) Awned. Applied to leaves, leaf-stalks, &c. when terminated by a long rigid spine, which in a leaf does not appear as a contraction. In *Galium aristatum*, the leaf-stalk is awned.

ARISTOLO′CHIA. (*Aristolochia, æ. f.*; from *αριστος*, good, and *λοχια* or *λοχεια*, parturition; so called because it was supposed to be of sovereign use in disorders incident to child-birth. 1. The name of a genus of plants in the Linnæan system. Class, *Gynandria*; Order, *Hexandria.*

2. The pharmacopœial name of the long-rooted birthwort. See *Aristolochia longa.*

ARISTOLOCHIA ANGUICIDA. Snake-killing birthwort. *Aristolochia—foliis cordatis, acuminatis; caule volubili, fructicoso; pedunculis solitariis; stipulis cordatis*, of Linnæus. The juice of the root of this plant has the property of so stupifying serpents, that they may be handled with impunity. One or two drops are sufficient; and if more be dropt into the mouth, they become convulsed. So ungrateful is the smell of the root to those reptiles, that it is said they immediately turn from it. The juice is also esteemed as a preventive against the effects usually produced by the bite of venomous serpents.

ARISTOLOCHIA CLEMATITIS. *Aristolochia tenuis.* The systematic name of the *Aristolochia vulgaris* of some pharmacopœias. An extract is ordered by the Wirtemberg Pharmacopœia, and the plant is retained in that of Edinburgh. It is esteemed as possessing antipodagric virtues.

ARISTOLOCHIA FABACEA. See *Fumaria bulbosa.*

ARISTOLOCHIA LONGA. The systematic name for the aristolochia of our pharmacopœias. *Aristolochia:—foliis cordatis, petiolatis, integerri-*

mis, obtusiusculis; caule infirmo, floribus solitariis. The root of this plant only is in use; it possesses a somewhat aromatic smell, and a warm bitterish taste, accompanied with a slight degree of pungency. The virtues ascribed to this root by the ancients were very considerable; and it was frequently employed in various diseases, but particularly in promoting the discharge of the *lochia;* hence its name. It is now very rarely used, except in gouty affections, as an aromatic stimulant.

ARISTOLOCHIA ROTUNDA. The root of this species of birthwort, *Aristolochia—foliis cordatis, subsessilibus, obtusis; caule infirmo; floribus solitariis,* of Linnæus; is used indiscriminately with that of the *aristolochia longa.* See *Aristolochia longa.*

ARISTOLOCHIA SERPENTARIA. The systematic name for the *Serpentaria virginiana* of the pharmacopœias. *Aristolochia; Colubrina virginiana; Viperina; Viperina virginiana; Pestilochia; Contrayerva virginiana.* Virginian snake-root. The plant which affords this root is the *Aristolochia—foliis cordato oblongis planis; caulibus infirmis flexuosis teretibus; floribus solitariis. Caulus geniculata valde nodosa. Flores ad radicem* of Linnæus. Snake-root has an aromatic smell, approaching to that of valerian, but more agreeable; and a warm, bitterish, pungent taste. It was first recommended as a medicine of extraordinary power in counteracting the poisonous effects of the bites of serpents; this, however, is now wholly disregarded: but as it possesses tonic and antiseptic virtues, and is generally admitted as a powerful stimulant and diaphoretic, it is employed, in the present day, in some fevers where these effects are required. A tinctura is directed both by the London and Edinburgh Pharmacopœias.

ARISTOLOCHIA TENUIS. See *Aristolochia clematitis.*

ARISTOLOCHIA TRILOBATA. Three-lobed birthwort. The root, and every part of this plant, *Aristolochia foliis trilobis, caule volubili, floribus maximis* of Linnæus, is diuretic, and is employed in America against the bite of serpents.

ARISTOLOCHIA VULGARIS. See *Aristolochia clematitis.*

ARISTOPHANEI'ON. (From *Aristophanes,* its inventor.) The name of an ancient emollient plaster, composed of wax, or pitch.—*Gorræus.*

ARMA. (*Arma, orum. pl. n.* Arms.) In botany, applied to a species of armature or offensive weapons. They are one of the seven kinds of *fulcra,* or props of plants enumerated by Linnæus in his *Delineatio plantæ.* They are pungent points in some part of a plant. In the present day, arma is used as a generic term embracing the *aculeus, furca, spina,* and *stimulus.*

ARMATU'RA. 1. See *Arma.*

2. The amnios or internal membrane which surrounds the fœtus.

ARMATURE. See *Arma.*

A'RME. (From *αρω,* to adapt.) 1. A junction of the lips of wounds.

2. The joining of the sutures of the head.

ARMI'LLA. (Diminutive of *armus,* the arm.) The round ligament which confines the tendons of the carpus.

ARMORA'CIA. (From *Armorica,* the country whence it was brought. See *Cochlearia Armoracia.*

ARMSTRONG, JOHN, a Scotch physician, born in 1709, who, after graduating at Edinburgh, settled in London, but met with little success, having distinguished himself less in his profession than as a poet, particularly by his "Essay on the Art of Preserving Health," in blank verse. He afterwards attended the army in Germany, which brought him more into notice as a physician. He attained the age of seventy, and died in pretty good circumstances. His professional publications are not of much note; the principal one is entitled "Medical Essays." He is supposed, however, to have contributed materially to a useful Treatise on the Diseases of Children, published by his brother George, who, after practising many years as an apothecary, obtained a diploma in medicine.

A'RNICA. (*Arnica, æ.* f. Αρνικη; from *αρς,* a lamb; because of the likeness of the leaf of this plant to the coat of the lamb.) Arnica. 1. The name of a genus of plants in the Linnæan system. Class, *Syngenesia;* Order, *Polygamia superflua.*

2. The pharmacopœial name of the Mountain arnica. See *Arnica montana.*

ARNICA MONTANA. The systematic name for the *arnica* of the pharmacopœias. *Arnica—foliis ovatis integris; caulinis geminis oppositis,* of Linnæus. *Doronicum Germanicum. Acyrus.* The flowers of this plant are very generally employed on the Continent. Of the advantages derived from their use, in paralytic and other affections, depending upon a want of nervous energy, there are several proofs; and their extraordinary virtues, as a febrifuge and antiseptic, have been highly extolled by Dr. Collin, of Vienna. Much caution is necessary in regulating the dose, as it is a medicine very apt to produce vomiting and much uneasiness of the stomach. See *Arnica.*

ARNICA SUEDENSIS. See *Inula dysenterica.*

ARNO'TTO. A Spanish name for a shrub. See *Bixa orleana.*

ARO'MA. (*Aroma, matis.* neut.; from *αρι,* intensely, and *οζω,* to smell.) *Spiritis rector.* The odorous principle of plants, and other substances, which have their characteristic smell. This is called by the moderns, *aroma.* Water charged with aroma, is called the distilled water of the substance made use of: thus lavender and peppermint waters are water impregnated with the aroma of the lavender and peppermint.

AROMATA. (Αρωματα, sweet spices, herbs, &c.) Aromatics.

AROMA'TIC. (*Aromaticus;* from *αρωμα,* an odour.) A term applied to a grateful spicy scent, and an agreeable pungent taste, as cinnamon bark, cardamoms, &c.

Aromatic vinegar. See *Acetum aromaticum.*

AROMATICÆ PLANTÆ. Odoriferous or strong and agreeable smelling plants. The name of a class of plants in some natural arrangements.

AROMA'TICUS CORTEX. A name for canella alba. *Cortex winteranus.*

AROMATOPO'LA. (From *αρωμα,* an odour, and *πωλεω,* to sell.) A druggist; a vender of drugs and spiceries.

ARQUEBUSA'DE. (A French word, implying *good for a gun-shot wound.*) *Aqua sclopetaria; Aqua vulneraria; Aqua catapultarum.* The name of a spirituous water, distilled from a farrago of aromatic plants.

ARRA'CK. A spirituous liquor distilled from rice, and drunk, in the rice countries, as brandy is in this island. Its effects on the animal economy are the same.

ARRAGONITE. A mineral of a greenish and pearly gray colour, found at Arragon in Spain, England, and Scotland.

A'RRAPHUS. (From *α*, priv. and *ραφη*, a suture.) Without suture. It is applied to the cranium when naturally without sutures.

ARRHÆ'A. (From *α*, neg. and ῥεω, to flow.) The suppression of any natural flux, as the menses, &c.

ARRHIZUS. (From *α*, priv. and *ριζα*, a root: without root.) Applied to paraatical plants, which have no roots, but adhere and imbibe their nourishment by ainastomosing of the vessels; as *Viscum album*, and *Loranthus europeus.*

ARROWHEAD. The *Sagittaria sagittifolia* of Linnæus. The roots of this plant are said to be esculent, but it must be in times of very great scarcity.

Arrow-root. See *Maranta.*

Arrow-shaped. See *Leaf.*

ARSE'NIATE. (*Arsenias, atis.* m.; from *arsenicum*, arsenic.) A salt formed by a combination of arsenic acid with salifiable bases; as arseniate of ammonia, which is produced by the union of ammonia with arsenic acid. The only one used in medicine is the superarseniate of potassa, which is in solution in the liquor arsenicalis. See *Arsenicalis liquor.*

A'RSENIC. (*Arsenicum, i.* n.; from the Arabic term *Arsanek*, or from *αρσην*, for *αρρην*, *masculus*; from its strong and deadly powers.) The name of a metal scattered, in great abundance, over the mineral kingdom. It is found in black heavy masses of little brilliancy, called *native arsenic* or testaceous arsenic. This exists in different parts of Germany. Mineralised by sulphur, it forms *sulphurised arsenic.* This mineral is met with in Italy, about Mount Vesuvius. There are two varieties of this ore, which differ from each other in colour, occasioned by the different proportions of their component parts. The one is called yellow *sulphurised arsenic*, or *orpiment*; the other, *red sulphurised arsenic*, or *realgar*, or *ruby arsenic*; both are met with in Hungary and different parts of Germany. The colour of the first ore is a lemon-yellow, inclining sometimes to a green; the colour of the latter is a ruby-red; it is more transparent than the former, and found in compact solid masses, sometimes crystallised in bright needles. Arsenic united to oxygen, constitutes the ore called *native oxyde of arsenic.* This ore is scarce; it is generally found of an earthy appearance, or as an efflorescence, coating native, or metallic arsenic; its colour is a whitish gray; it is rarely met with crystallised. Arsenic exists likewise alloyed with cobalt, antimony, tin, copper, lead, and various other metals.

Method of obtaining Arsenic. In order to obtain metallic arsenic, mix two parts of the white oxyde of arsenic of commerce, with one of black flux (obtained by detonating one part of nitrate of potassa with two of supertartrate of potassa,) and put the mixture into a crucible, or melting pot. Invert over this another crucible, lute the two together with a little clay and sand, and apply gradually a red heat to the lower one. The oxyde of arsenic will be reduced, and be found lining the upper crucible in small crystals of a metallic brilliancy.

The charcoal of the black flux takes in this process the oxygen from the white oxyde, and forms carbonic acid gas; which flies off during the process, and the oxyde becomes reduced to the metallic state. This reduction of the oxyde is greatly facilitated by the alkali of the flux.

Remark.—In order to obtain arsenic in a state of absolute purity, the metal thus obtained must be reduced to a powder, dissolved by heat in nitro-muriatic acid, and then precipitated by immersing into the solution a plate of zinc. The arsenic is thus precipitated in a fine powder, and may be reduced to a mass, by exposing it in a covered crucible to a moderate heat.

“It is among the most combustible of the metals, burns with a blue flame, and garlic smell, and sublimes in the state of arsenious acid.

Concentrated sulphuric acid does not attack arsenic when cold; but if it be boiled upon this metal, sulphurous acid gas is emitted, a small quantity of sulphur sublimes, and the arsenic is reduced to an oxyde.

Nitrous acid readily attacks arsenic, and converts it into arsenious acid, or, if much be employed, into arsenic acid.

Boiling muriatic acid dissolves arsenic, but effects it very little when cold. This solution affords precipitates upon the addition of alkalies. The addition of a little nitric acid expedites the solution; and this solution, first heated and condensed in a close vessel, is wholly sublimed into a thick liquid, formerly termed *butter of arsenic.* Thrown in powder into chlorine gas, it burns with a bright white flame, and is converted into a chloride.

None of the earths or alkalies act upon it, unless it be boiled a long while in fine powder, in a large proportion of alkaline solution.

Nitrates detonate with arsenic, convert it into arsenic acid, and this, combining with the base of the nitrate, forms an arseniate, that remains at the bottom of the vessel.

Muriates have no action upon it; but if three parts of chlorate of potassa be mixed with one part of arsenic in fine powder, which must be done with great precaution, and a very light hand, a very small quantity of this mixture placed on an anvil, and struck with a hammer, will explode with flame and a considerable report; if touched with fire, it will burn with considerable rapidity; and if thrown into concentrated sulphuric acid, at the instant of contact a flame rises into the air like a flash of lightning, which is so bright as to dazzle the eye.

Arsenic readily combines with sulphur by fusion and sublimation, and forms a yellow compound called *orpiment*, or a red called *realgar.* The nature of these, and their difference, are not accurately known; but Fourcroy considers the first as a combination of sulphur with the oxyde, and the second as a combination of sulphur with the metal itself, as he found the red sulphuret converted into the yellow by the action of acids.

Arsenic is soluble in fat oils in a boiling heat; the solution is black, and has the consistence of an ointment when cold. Most metals unite with arsenic; which exists in the metallic state in such alloys as possess the metallic brilliancy.

Iodine and arsenic unite, forming an iodide, of a dark purple-red colour, possessing the properties of an acid. It is soluble in water, and its solution forms a soluble compound with potassa.

Arsenic combines with hydrogen into a very noxious compound, called arsenuretted hydrogen gas. To prepare it, fuse in a covered crucible 3 parts of granulated tin, and 1 of metallic arsenic in powder; and submit this alloy, broken in pieces, to the action of muriatic acid in a glass retort. On applying a moderate heat, the arsenuretted hydrogen comes over, and may be received in a mercurial or water pneumatic trough. Protomuriate of tin remains in the retort.

A prime equivalent of hydrogen is to one of arsenic as 1 to 76; and 2 consequently as 1 to 38.

Gehlen fell a victim to his researches on this gas; and therefore the new experiments requisite to elucidate its constitution must be conducted with circumspection. It extinguishes flame, and instantly destroys animal life. Water has no effect upon it. From the experiments of Sir H. Davy, and Gay Lussac and Thenard, there appears to be a solid compound of hydrogen and arsenic, or a hydruret. It is formed by acting with the negative pole of a voltaic battery on arsenic plunged in water. It is reddish brown, without lustre, taste, and smell. It is not decomposed at a heat approaching to cherry-red; but at this temperature it absorbs oxygen; while water and arsenious acid are formed, with the evolution of heat and light. The proportion of the two constituents is not known.

Arsenic is used in a variety of arts. It enters into metallic combinations, wherein a white colour is required. Glass manufacturers use it; but its effect in the composition of glass does not seem to be clearly explained. Orpiment and realgar are used as pigments."

Arsenic and its various preparations are the most active of all poisons. That which is mostly taken, is the white oxyde, or arsenious acid. See *Arsenious acid.*

ARSENIC ACID. *Acidum arsenicum; Acidum arsenicale.* "We are indebted to the illustrious Scheele for the discovery of this acid, though Macquer had before noticed its combinations. It may be obtained by various methods. If six parts of nitric acid be poured on one of the concrete arsenious acids, or white arsenic of the shops, in the pneumato-chemical apparatus, and heat be applied, nitrous gas will be evolved, and a white concrete substance, differing in its properties from the arsenious acid, will remain in the retort. This is the arsenic acid. It may equally be procured by means of aqueous chlorine, or by heating concentrated nitric acid with twice its weight of the solution of the arsenious acid in muriatic acid. The concrete acid should be exposed to a dull red heat for a few minutes. In either case an acid is obtained, that does not crystallise, but attracts the moisture of the air, has a sharp caustic taste, reddens blue vegetable colours, is fixed in the fire, and of the specific gravity of 3.391.

If the arsenic acid be exposed to a red heat in a glass retort, it melts and becomes transparent, but assumes a milky hue on cooling. If the heat be increased, so that the retort begins to melt, the acid boils, and sublimes into the neck of the retort. If a covered crucible be used instead of the glass retort, and a violent heat applied, the acid boils strongly, and in a quarter of an hour begins to emit fumes. These, on being received in a glass bell, are found to be arsenious acid; and a small quantity of a transparent glass, difficult to fuse, will be found lining the sides of the crucible. This is arseniate of alumina.

Combustible substances decompose this acid. If two parts of arsenic acid be mixed with about one of charcoal, the mixture introduced into a glass retort, coated, and a matrass adapted to it; and the retort then gradually heated in a reverberatory furnace, till the bottom is red; the mass will be inflamed violently, and the acid reduced, and rise to the neck of the retort in the metallic state, mixed with a little oxyde and charcoal powder. A few drops of water, devoid of acidity, will be found in the receiver.

With sulphur the phenomena are different. If a mixture of six parts of arsenic acid, and one of powdered sulphur, be digested together, no change will take place; but on evaporating to dryness, and distilling in a glass retort, fitted with a receiver, a violent combination will ensue, as soon as the mixture is sufficiently heated to melt the sulphur. The whole mass rises almost at once, forming a red sublimate, and sulphurous acid passes over into the receiver.

If pure arsenic acid be diluted with a small quantity of water, and hydrogen gas, as it is evolved by the action of sulphuric acid on iron, be received into this transparent solution, the liquor grows turbid, and a blackish precipitate is formed, which, being well washed with distilled water, exhibits all the phenomena of arsenic. Sometimes, too, a blackish-gray oxyde of arsenic is found in this process.

If sulphuretted hydrogen gas be employed instead of simple hydrogen gas, water and a sulphuret of arsenic are obtained.

With phosphorus, phosphoric acid is obtained, and a phosphuret of arsenic, which sublimes.

The arsenic acid is much more soluble than the arsenious. According to Lagrange, two parts of water are sufficient for this purpose. It cannot be crystallised by any means; but, on evaporation, assumes a thick honey-like consistence.

No acid has any action upon it: if some of them dissolve it by means of the water that renders them fluid, they do not produce any alteration in it. The boracic and phosphoric are vitrifiable with it by means of heat, but without any material alteration in their natures. If phosphorus acid be heated upon it for some time, it saturates itself with oxygen, and becomes phosphoric acid.

The arsenic acid combines with the earthy and alkāline bases, and forms salts very different from those furnished by the arsenious acid.

All these *arseniates* are decomposable by charcoal, which separates arsenic from them by means of heat.

All its *salts*, with the exception of those of potassa, soda, and ammonia, are insoluble in water; but except arseniate of bismuth, and one or two more, very soluble in an excess of arsenic acid. Hence, after barytes or oxyde of lead has been precipitated by this acid, its farther addition redissolves the precipitate. This is a useful criterion of the acid, joined to its reduction to the metallic state by charcoal, and the other characters already detailed. Sulphuric acid decomposes the arseniates at a low temperature, but the sulphates are decomposed by arsenic acid at a red heat, owing to the greater fixity of the latter. Phosphoric, nitric, muriatic, and fluoric acids, dissolve, and probably convert into subsalts all the arseniates. The whole of them, as well as arsenic acid itself when decomposed at a red heat by charcoal, yield the characteristic garlic smell of the metallic vapour. Nitrate of silver gives a pulverulent brick-coloured precipitate, with arsenic acid. The acid itself does not disturb the transparency of a solution of sulphate of copper; but a neutral arseniate gives with it a bluish-green precipitate; with sulphate of cobalt, a dirty red; and with sulphate of nickel, an apple-green precipitate. These precipitates redissolve, on adding a small quantity of the acid which previously held them in solution. Orfila says, that arsenic acid gives, with acetate of copper, a bluish-white precipitate, but that it exercises no action either on the muriate or acetate of cobalt; but with the ammonio-muriate, it gives a rose-coloured precipitate. Arsenic acid ought to be accounted a more violent poison than even the arsenious.

The *arseniate of barytes* is insoluble, uncrystallisable, soluble in an excess of its acid, and decomposable by sulphuric acid, which precipitates a sulphate of barytes.

The *bin-arseniate of potassa* is made on the great scale in Saxony, by fusing together equal parts of nitre and arsenious acid; dissolving the melted mass, and crystallising the salt.

Of the *arseniate of strontian* nothing is known, but no doubt it resembles that of barytes.

With *lime-water* this acid forms a precipitate of *arseniate of lime*, soluble in an excess of its base, or in an excess of its acid, though insoluble alone. The acidulous arseniate of lime affords on evaporation little crystals, decomposable by sulphuric acid. The same salt may be formed by adding carbonate of lime to the solution of arsenic acid. This acid does not decompose the nitrate or muriate of lime; but the saturated alkaline arseniates decompose them by double affinity, precipitating the insoluble calcareous arseniate.

If arsenic acid be saturated with *magnesia*, a thick substance is formed near the point of saturation. This *arseniate of magnesia* is soluble in an excess of acid; and on being evaporated takes the form of a jelly, without crystallising. Neither the sulphate, nitrate, nor muriate of magnesia is decomposed by arsenic acid, though they are by the saturated alkaline arseniates.

Arsenic acid, saturated with *potassa*, does not easily crystallise. This *arseniate*, being evaporated to dryness, attracts the humidity of the air, and turns the syrup of violets green, without altering the solution of litmus. It fuses into a white glass, and with a strong fire is converted into an acidule, part of the alkali being abstracted by the silex and alumina of the crucible. If exposed to a red heat with charcoal in close vessels, it swells up very much, and arsenic is sublimed. It is decomposed by sulphuric acid; but in the humid way the decomposition is not obvious, as the arsenic acid remains in solution. On evaporation, however, this acid and sulphate of potassa are obtained.

If arsenic acid be added to the preceding salt, till it ceases to have any effect on the syrup of violets, it will redden the solution of litmus; and in this state it affords very regular and very transparent crystals, of the figure of quadrangular prisms, terminated by two tetraëdral pyramids, the angles of which answer to those of the prisms. These cristals are the arsenical neutral salt of Macquer. As this salt differs from the preceding arseniate by its crystallisability, its reddening solution of litmus, its not decomposing the calcareous and magnesian salts like it, and its capability of absorbing an additional portion of potassa, so as to become neutral, it ought to be distinguished from it by the term of *acidulous arseniate of potassa*.

With *soda* in sufficient quantity to saturate it, arsenic acid forms a salt crystallisable like the acidulous arseniate of potassa. To form the neutral arseniate, carbonate of soda should be added to the acid, till the mixture be decidedly alkaline. This salt crystallises from the concentrated solution. It is much more soluble in hot than in cold water. Pelletier says, that the crystals are hexaëdral prisms, terminated by planes perpendicular to their axis. This neutral arseniate of soda, however, while it differs completely from that of potassa in this respect, and in becoming deliquescent instead of crystallisable on the addition of a surplus portion of arsenic acid, resembles the arseniate of potassa in its decomposition by charcoal, by acids, and by the earths.

Combined with *ammonia*, arsenic acid forms a salt affording rhomboidal crystals analogous to those of the nitrate of soda.

The *arseniate of soda* and *ammonia* is formed by mixing the two separate arseniates; and the compound salt gives crystals with brilliant faces. If we redissolve the crystals, and then recrystallise, we should add a little ammonia, otherwise the salt will be acidulous from the escape of some ammonia.

Arsenic acid saturated with *alumina* forms a thick solution, which, being evaporated to dryness, yields a salt insoluble in water, and decomposable by the sulphuric, nitric, and muriatic acids, as well as by all the other earthy and alkaline bases. The arsenic acid readily dissolves the alumina of the crucibles in which it is reduced to a state of fusion; and thus it attacks silex also, on which it has no effect in the humid way.

By the assistance of a strong fire, as Fourcroy asserts, arsenic acid decomposes the alkaline and earthy sulphates, even that of barytes; the sulphuric acid flying off in vapour, and the arseniate remaining in the retort. It acts in the same manner on the nitrate, from which it expels the pure acid. It likewise decomposes the muriates at a high temperature, the muriatic acid being evolved in the form of gas, and the arsenic acid combining with their bases, which it saturates; while the arsenious acid is too volatile to have this effect. It acts in the same manner on the fluates, and still more easily on the carbonates, with which, by the assistance of heat, it excites a brisk effervescence. Lagrange, however, denies that it acts on any of the neutral salts, except the sulphate of potassa and soda, the nitrate of potassa, and the muriates of soda and ammonia, and this by means of heat. It does not act on the phosphates, but precipitates the boracic acids from solutions of borates when heated.

Arsenic acid does not act on gold or platina; neither does it on mercury or silver, without the aid of a strong heat; but it oxydises copper, iron, lead, tin, zinc, bismuth, antimony, cobalt, nickel, manganese, and arsenic.

This acid is not used in the arts, at least directly, though indirectly it forms a part of some compositions used in dyeing. It is likewise one of the mineralising acids combined by nature with some of the metallic oxydes."—*Ure's Chem. Dict.*

Arsenic, oxyde of. See *Arsenious acid.*

Arsenic, white. See *Arsenious acid.*

ARSE'NICAL CAUSTIC. A species of caustic said to possess useful properties, independent of those of destroying morbid parts to which it is applied. It is composed of two parts of levigated antimony to one of white arsenic. This is the caustic so extensively employed under the name of arsenical caustic, by the late Mr. Justamond, in his treatment of cancers.

ARSENICA'LIS LIQUOR. Arsenical solution. Take of sublimed oxyde of arsenic, in very fine powder, subcarbonate of potassa from tartar, of each 64 grains; distilled water a pint. Boil them together in a glass vessel, until the arsenic be entirely dissolved. When the solution is cold, add compound spirit of lavender, four fluid drachms. Then add as much distilled water as may exactly fill a pint measure. This preparation accords with the formula of Dr. Fowler, of Stafford, who first introduced it in imitation of a celebrated popular remedy for intermittents, sold under the name of the tasteless ague-drop. The compound spirit of lavender is only intended to give some colour and taste, without which it would be more liable to mistakes. Where the dose is small, and the effects so powerful, the most minute attention to its proportion and preparation becomes necessary. Each ounce contains four grains of the oxyde, and each drachm half a grain; but it will rarely be proper to go beyond one-sixteenth of a grain as a dose.

Arsenical solution. See *Arsenicalis liquor.*

Arsenici oxydum præparatum. See *Arsenici oxydum sublimatum.*

ARSENICUM ALBUM. *Arsenici oxydum sublimatum; Arsenici oxydum præparatum.* Reduce white arsenic into powder, then put it into a crucible and expose it to the fire, so as to sublime it into another crucible inverted over the former. This is intended to render the arsenic more pure.

Arsenicum album. White arsenic. See *Arsenious acid.*

ARSENICUM CRYSTALLINUM. See *Arsenious acid.*

ARSE'NIOUS ACID. White arsenic. Oxyde of arsenic. *Arsenicum crystallinum, risigallum, aquala, arfar, aquila, zarnick, artaneck.* Rat's bane. The earliest chemists were embarrassed in the determination of the nature of the poisonous white substance known in commerce by the name of *white arsenic.* "Fourcroy was the first who distinguished by this name the white arsenic of the shops, which Scheele had proved to be a compound of the metal arsenic with oxygen, and which the authors of the new chemical nomenclature had consequently termed oxyde of arsenic. As, however, it manifestly exhibits the properties of an acid, it has a fair claim to the title; for many oxydes and acids are similar in this, that both consist of a base united with oxygen, and the only difference between them is, that the compound in which the acid properties are manifest is termed an acid, and that in which they are not is called an oxyde.

This acid, which is one of the most virulent poisons known, frequently occurs in a native state, if not very abundantly; and it is obtained in roasting several ores, particularly those of cobalt. In the chimneys of the furnaces where this operation is conducted, it generally condenses in thick semitransparent masses; though sometimes it assumes the form of a powder, or of little needles, in which state it was formerly called flowers of arsenic.

The arsenious acid reddens the most sensible blue vegetable colours, though it turns the syrup of violets green. On exposure to the air it becomes opaque, and covered with a slight efflorescence. Thrown on incandescent coals, it evaporates in white fumes, with a strong smell of garlic. In close vessels it is volatilised; and, if the heat be strong, vitrified. The result of this vitrification is a transparent glass, capable of crystallising in tetraëdra, the angles of which are truncated. It is easily altered by hydrogen and carbon, which deprive it of its oxygen at a red heat, and reduce the metal, the one forming water, the other carbonic acid, with the oxygen taken from it; as it is by phosphorus, and by sulphur, which are in part converted into acids by its oxygen, and in part form an arsenical phosphuret or sulphuret with the arsenic reduced to the metallic state. Hence Margraaf and Pelletier, who particularly examined the phosphurets of metals, assert they might be formed with arsenious acid. Its specific gravity is 3.7.

It is soluble in thirteen times its weight of boiling water, but requires eighty times its weight of cold. The solution crystallises, and the acid assumes the form of regular tetraëdrons, according to Fourcroy; but, according to Lagrange, of octaëdrons, and these frequently varying in figure by different laws of decrement. It crystallises much better by slow evaporation than by simple cooling.

The solution is very acrid, reddens blue colours, unites with the earthy bases, and decomposes the alkaline sulphurets. Arsenious acid is also soluble in oils, spirits, and alcohol; the last taking up from 1 to 2 per cent. It is composed of 9.5 of metal = 3 oxygen; and its prime equivalent is therefore 12.5. Dr. Wollaston first observed, that when a mixture of it with quicklime is heated in a glass tube, at a certain temperature, ignition suddenly pervades the mass, and metallic arsenic sublimes. As arseniate of lime is found at the bottom of the tube, we perceive that a portion of the arsenious acid is robbed of its oxygen, to complete the acidification of the rest.

There are even some metals, which act upon the solution, and have a tendency to decompose the acid so as to form a blackish precipitate, in which the arsenic is very slightly oxydised.

The action of the other acids upon the arsenious is very different from that which they exert on the metal arsenic. By boiling, sulphuric acid dissolves a small portion of it, which is precipitated as the solution cools. The nitric acid does not dissolve it, but by the help of heat converts it into arsenic acid. Neither the phosphoric nor the carbonic acid acts upon it; yet it enters into a vitreous combination with the phosphoric and boracic acids. The muriatic acid dissolves it by means of heat, and forms with it a volatile compound, which water precipitates; and aqueous chlorine acidifies it completely, so as to convert it into arsenic acid.

The arsenious acid combines with the *earthy* and *alkaline* bases, forming *Arsenites.* The earthy arseniates possess little solubility; and hence the solutions of barytes, strontian, and lime, form precipitates with that of arsenious acid.

This acid enters into another kind of combination with the earths, that formed by *vitrification.* Though a part of this volatile acid sublimes before the glass enters into fusion, part remains fixed in the vitrified substance, to which it imparts transparency, a homogeneous density, and considerable gravity. The arsenical glasses appear to contain a kind of triple salt, since the salt and alkalies enter into an intimate combination at the instant of fusion, and remain afterward perfectly mixed. All of them have the inconvenience of quickly growing dull by exposure to the air.

With the *fixed alkalies* the arsenious acid forms thick arsenites, which do not crystallise; which are decomposable by fire, the arsenious acid being volatilised by the heat; and from which all the other acids precipitate this in powder. These saline compounds were formerly termed livers, because they were supposed to be analogous to the combinations of sulphur with the alkalies.

With *ammonia* it forms a salt capable of crystallisation. If this be heated a little, the ammonia is decomposed, the nitrogen is evolved, while the hydrogen, uniting with part of the oxygen of the acid, forms water.

Neither the earthy nor alkaline arsenites have yet been much examined; what is known of them being only sufficient to distinguish them from the arseniates.

The arsenious acid is used in numerous instances in the arts, under the name of *white arsenic,* or of arsenic simply. In many cases it is reduced, and acts in its metallic state.

Many attempts have been made to introduce it into medicine; but as it is known to be one of the most violent poisons, it is probable that the fear of its bad effects may deprive society of the advantages it might afford in this way. An arseniate of potassa was extensively used by the late Dr. Fowler of York, who published a treatise on it, in intermittent and remittent fevers. He likewise assured the writer, that he had found it extremely efficacious in periodical headache, and as a tonic in nervous and other disorders; and that he never saw the least ill effect from its use, due precaution being employed in preparing and administering it. Externally it has been employed as a caustic to extirpate cancer, combined with sulphur, with bole, with antimony, and with the leaves of crowfoot; but it always gives great pain, and is not unattended with danger. Febvre's remedy was water one pint, extract of hemlock ℥j. Goulard's extract ℥iij. tincture of opium ʒj. arsenious acid gr. x. With this the cancer was wetted morning and evening; and at the same time a small quantity of a weak solution was administered internally. A still milder application of this kind has been made from a solution of one grain in a quart of water, formed into a poultice with crumb of bread.

It has been more lately used as an alterative with advantage in chronic rheumatism. The symptoms which show the system to be *arsenified* are thickness, redness, and stiffness of the *palpebræ*, soreness of the gums, ptyalism, itching over the surface of the body, restlessness, cough, pain at stomach, and headache. When the latter symptoms supervene, the administration of the medicine ought to be immediately suspended. It has also been recommended against chincough; and has been used in considerable doses with success, to counteract the poison of venemous serpents.

Since it acts on the animal economy as a deadly poison in quantities so minute as to be insensible to the taste when diffused in water or other vehicles, it has been often given with criminal intentions and fatal effects. It becomes therefore a matter of the utmost importance to present a systematic view of the phenomena characteristic of the poison, its operation, and consequences.

It is a dense substance, subsiding speedily after agitation in water. Dr. Ure found its sp. gr. to vary from 3.728 to 3.730, which is a little higher than the number given above; 72 parts dissolve in 1000 of boiling water, of which 30 remain in it, after it cools. Cold water dissolves, however, only 3-1000 or 1-10 of the preceding quantity. This water makes the syrup of violets green, and reddens litmus paper. Lime water gives a fine white precipitate with it of arsenite of lime, soluble in an excess of the arsenious solution; sulphuretted hydrogen gas, and hydrosulphuretted water, precipitate a golden yellow sulphuret of arsenic. By this means 1-100000 of arsenious acid may be detected in water. This sulphuret dried on a filter, and heated in a glass tube with a bit of caustic potassa, is decomposed in a few minutes, and converted into sulphuret of potassa, which remains at the bottom, and metallic arsenic of a bright steel lustre, which sublimes, coating the sides of the tube. The hydrosulphurets of alkalies do not affect the arsenious solution, unless a drop or two of nitric or muriatic acid be poured in, when the characteristic golden yellow precipitate falls. Nitrate of silver is decomposed by the arsenious acid, and a very peculiar yellow arsenite of silver precipitates; which, however, is apt to be redissolved by nitric acid, and therefore a very minute addition of ammonia is requisite. Even this, however, also, if in much excess, redissolves the silver precipitate.

As the nitrate of silver is justly regarded as one of the best precipitant tests of arsenic, the mode of using it has been a subject of much discussion. This excellent test was first proposed by Mr. Hume of Long Acre, in May 1809. *Phil. Mag.* xxxiii. 401. The presence of muriate of soda indeed, in the arsenical solution, obstructs, to a certain degree, the operation of this reagent. But that salt is almost always present in the *primæ viæ*, and is a usual ingredient in soups, and other vehicles of the poison. If, after the water of ammonia has been added, (by plunging the end of a glass rod dipped in it into the supposed poisonous liquid,) we dip another rod into a solution of pure nitrate of silver, and transfer it into the arsenious solution, either a fine yellow cloud will be formed, or at first merely a white curdy precipitate. But at the second or third immersion of the nitrate rod, a central spot of yellow will be perceived surrounded with the white muriate of silver. At the next immersion, this yellow cloud on the surface will become very conspicuous. Sulphate of soda does not interfere in the least with the silver test.

The ammoniaco-sulphate, or rather ammoniaco-acetate of copper, added in a somewhat dilute state to an arsenious solution, gives a fine grass-green and very characteristic precipitate. This green arseniate of copper, well washed, being acted on by an excess of sulphuretted hydrogen water, changes its colour, and becomes of a brownish-red. Ferro prussiate of potassa changes it into a blood-red. Nitrate of silver converts it into the yellow arsenite of silver.

Lastly, if the precipitate be dried on a filter, and placed on a bit of burning coal, it will diffuse a garlic odour. The cupreous test will detect 1-110000 of the weight of the arsenic in water.

The voltaic battery, made to act by two wires on a little arsenious solution placed on a bit of window-glass, developes metallic arsenic at the negative pole; and if this wire be copper, it will be whitened like tombac.

We may here remark, however, that the most elegant mode of using all these precipitation reagents is upon a plane of glass; a mode practised by Dr. Wollaston in general chemical research, to an extent, and with a success, which would be incredible in other hands than his. Concentrate by heat in a capsule the suspected poisonous solution, having previously filtered it if necessary. Indeed, if it be very much disguised with animal or vegetable matters, it is better first of all to evaporate to dryness, and by a few drops of nitric acid to dissipate the organic products. The clear liquid being now placed in the middle of the bit of glass, lines are to be drawn out from it in different directions. To one of these a particle of weak ammoniacal water being applied, the weak nitrate of silver may then be brushed over it with a hair pencil. By placing the glass in different lights, either over white paper or obliquely before the eye, the slightest change of tint will be perceived. The ammoniaco-acetate should be applied to another filament of the drop, deut-acetate of iron to a third, weak ammoniaco-acetate of cobalt to a fourth, sulphuretted water to a fifth, lime water to a sixth, a drop of violet-syrup to a seventh, and the two galvanic wires at the opposite edges of the whole. Thus with one single drop of solution many exact experiments may be made.

But the chief, the decisive trial or *experimentum crucis* remains, which is to take a little of the dry matter, mix it with a small pinch of dry black flux, put it into a narrow glass tube sealed at one end, and after cleansing its sides with a feather, urge its bottom with a blow-pipe till it be distinctly red-hot for a minute. Then garlic fumes will be smelt, and the steel-lustred coating of metallic arsenic will be seen in the tube about one-fourth of an inch above its bottom. Cut the tube across at that point by means of a fine file, detach the scale of arsenic with the point of a penknife; put a fragment of it into the bottom of a small wine-glass along with a few drops of ammoniaco-acetate of copper, and triturate them well together for a few minutes with a round-headed glass rod. The mazarine blue colour will soon be transmuted into a lively grass-green, while the metallic scale will vanish. Thus we distinguish perfectly between a particle of metallic arsenic and one of animalised charcoal. Another particle of the scale may be placed between two smooth and bright surfaces of copper, with a touch of fine oil; and whilst they are firmly pressed together, exposed to a red-heat. The tombac alloy will appear as a white stain. A third particle may be placed on a bit of heated metal, and held a little under the nostrils, when the garlic odour will be recognised. No danger can be apprehended, as the fragment need not exceed the tenth of a grain.

It is to be observed, that one or two of the precipitation tests may be equivocal from admixtures of various substances. Thus tincture of ginger gives with the cupreous reagent a green precipitate;—and the writer of this article was at first led to suspect from that appearance, that an empirical tincture, put into his hands for examination, did contain arsenic. But a careful analysis satisfied him of its genuineness. Tea covers arsenic from the cupreous test. Such poisoned tea becomes, by its addition, of an obscure olive or violet red, but yields scarcely any precipitate. Sulphuretted hydrogen, however, throws down a fine yellow sulphuret of arsenic.

The true way of obviating all these sources of fallacy, is to evaporate carefully to dryness, and expose the residue to heat in a glass tube. The arsenic sublimes, and may be afterwards operated on without ambiguity. M. Orfila has gone into ample details on the modifications produced by wine, coffee, tea, broth, &c. on arsenical tests, of which a good tabular abstract is given in Mr. Thomson's London Dispensatory. But it is evident that the differences in these menstrua, as also in beers, are so great as to render precipitations and changes of colour by reagents very unsatisfactory witnesses, in a case of life and death. Hence the method of evaporation above described should never be neglected. Should the arsenic be combined with oil, the mixture ought to be boiled with water, and the oil then separated by the capillary action of wick-threads. If with resinous substances, these may be removed by oil of turpentine, not by alcohol, (as directed by Dr. Black,) which is a good solvent of arsenious acid. It may moreover be observed, that both tea and coffee should be freed from their tannin by gelatin, which does not act on the arsenic, previous to the use of reagents for the poison. When one part of arsenious acid in watery solution is added to ten parts of milk, the sulphuretted hydrogen present in the latter, occasions the white colour to pass into a canary yellow; the cupreous test gives it slight green tint, and the nitrate of silver produces no visible change, though even more arsenic be added; but the hydrosulphurets throw down a golden yellow, with the aid of a few drops of an acid. The liquid contained in the stomach of a rabbit poisoned with a solution of three grains of arsenious acid, afforded a white precipitate with nitrate of silver, grayish-white with lime water, green with the ammoniaco-sulphate, and deep yellow with sulphuretted hydrogen water.

The preceding copious description of the habitudes of arsenious acid in different circumstances, is equally applicable to the soluble arsenites. Their poisonous operation, as well as that of the arsenic acid, has been satisfactorily referred by Mr. Brodie to the suspension of the functions of the heart and brain, occasioned by the absorption of these substances into the circulation, and their consequent determination to the nervous system and the alimentary canal. This proposition was established by numerous experiments on rabbits and dogs. Wounds were inflicted, and arsenic being applied to them, it was found that in a short time death supervened with the same symptoms of inflammation of the stomach and bowels, as if the poison had been swallowed.

He divides the morbid affections into three classes: 1*st*, Those depending on the nervous system, as palsy at first of the posterior extremities, and then of the rest of the body, convulsions, dilatation of the pupils, and general insensibility: 2*d*, Those which indicate disturbance in the organs of circulation; for example, the feeble, slow, and intermitting pulse, weak contractions of the heart immediately after death, and the impossibility of prolonging them, as may be done in sudden deaths from other causes, by artificial respiration: 3*d*, Lastly, those which depend on lesion of the alimentary canal, as the pains of the abdomen, nauseas and vomitings, in those animals which were suffered to vomit. At one time it is the nervous system that is most remarkably affected, and at another the organs of circulation. Hence inflammation of the stomach and intestines, ought not to be considered as the immediate cause of death, by the greater number of cases of poisoning by arsenic. However, should an animal not sink under the first violence of the poison, if the inflammation has had time to be developed, there is no doubt that it may destroy life. Mr. Earl states, that a woman who had taken arsenic resisted the alarming symptoms which at first appeared, but died on the fourth day. On opening her body the mucous membrane of the stomach and intestines was ulcerated to a great extent. Authentic cases of poison are recorded, where no trace of inflammation was perceptible in the *primæ viæ*.

The effects of arsenic have been graphically represented by Dr. Black: 'The symptoms produced by a dangerous dose of arsenic begin to appear in a quarter of an hour, or not much longer, after it is taken. First sickness, and great distress at stomach, soon followed by thirst, and burning heat in the bowels. Then come on violent vomiting and severe colic pains, and excessive and painful purging. This brings on faintings, with cold sweats, and other signs of great debility. To this succeed painful cramps, and contractions of the legs and thighs, and extreme weakness, and death.' Similar results have followed the incautious sprinkling of schirrous ulcers with powdered arsenic, or the application of arsenical pastes. The following more minute specification of symptoms is given by Orfila: 'An austere taste in the mouth; frequent ptyalism; continual spitting; constriction of the *pharynx* and *œsophagus*; teeth set on edge; hiccups; nausea; vomiting of brown or bloody matter; anxiety; frequent fainting fits; burning heat at the *precordia*; inflammation of the lips, tongue, palate, throat, stomach; acute pain of stomach, rendering the mildest drinks intolerable; black stools of an indescribable fœtor; pulse frequent, oppressed, and irregular, sometimes slow and unequal; palpitation of the heart; *syncope;* unextinguishable thirst; burning sensation over the whole body, resembling a consuming fire; at times an icy coldness; difficult respiration; cold sweats; scanty urine, of a red or bloody appearance; altered expression of countenance; a livid circle round the eye-lids; swelling and itching of the whole body, which becomes covered with livid spots, or with a miliary eruption; prostration of strength; loss of feeling, especially in the feet and hands; delirium, convulsions, sometimes accompanied with an insupportable priapism; loss of the hair; separation of the epidermis; horrible convulsions; and death.'

It is uncommon to observe all these frightful symptoms combined in one individual; sometimes they are altogether wanting, as is shown by the following case, related by M. Chaussier:—A robust man of middle age swallowed arsenious acid in large fragments, and died without experiencing other symptoms than slight *syncopes.* On opening his stomach, it was found to contain the arsenious acid in the very same state in which he had swallowed it. There was no appearance whatever of erosion or inflammation in the intestinal canal. Etmuller mentions a young girl's being poisoned by arsenic, and whose stomach and bowels were sound to all appearance, though the arsenic was found in them. In general, however, inflammation does extend along the whole canal, from the mouth to the *rectum.* The stomach and *duodenum* present frequently gangrenous points, eschars, perforations of all their coats; the villous coat in particular, by this and all other corrosive poisons, is commonly detached, as if it were scraped off or reduced into a paste of a reddish-brown colour. From these considerations we may conclude, that from the existence or non-existence of intestinal lesions, from the extent or seat of the symptoms alone, the physician should not venture to pronounce definitively on the fact of poisoning.

The result of Mr. Brodie's experiments on brutes teaches, that the inflammations of the intestines and stomach are more severe when the poison has been applied to an external wound, than when it has been thrown into the stomach itself.

The best remedies against this poison in the stomach, are copious draughts of bland liquids of a mucilaginous consistence, to inviscate the powder, so as to procure its complete ejection by vomiting. Sulphuretted hydrogen condensed in water, is the only direct antidote to its virulence; Orfila having found, that when dogs were made to swallow that liquid, after getting a poisonous dose of arsenic, they recovered, though their œsophagus was tied to prevent vomiting; but when the same dose of poison was administered in the same circumstances, without the sulphuretted water, that it proved fatal.

When the *viscera* are to be subjected after death to chemical investigation, a ligature ought to be thrown round the œsophagus and the beginning of the colon, and the intermediate stomach and intestines removed. Their liquid contents should be emptied into a basin; and thereafter a portion of hot water introduced into the stomach, and worked thoroughly up and down this *viscus,* as well as the intestines.

After filtration, a portion of the liquid should be concentrated by evaporation in a porcelain capsule, and then submitted to the proper reagents above described. We may also endeavour to extract from the stomach by digestion in boiling water, with a little ammonia, the arsenical impregnation, which has been sometimes known to adhere in minute particles with wonderful obstinacy. This precaution ought, therefore, to be attended to. The heat will dissipate the excess of ammonia in the above operation; whereas, by adding potassa or soda, as prescribed by the German chemists, we introduce animal matter in alkaline solution, which complicates the investigation.

The matters rejected from the patient's bowels before death, should not be neglected. These, generally speaking, are best treated by cautious evaporations to dryness; but we must beware of heating the residuum to 400°, since at that temperature, and perhaps a little under it, the arsenious acid itself sublimes.

Vinegar, hydroguretted alkaline sulphurets, and oils, are of no use as counterpoisons. Indeed, when the arsenic exists in substance in the stomach, even sulphuretted hydrogen water is of no avail, however effectually it neutralise an arsenious solution. Syrups, linseed tea, decoction of mallows, or tragacanth, and warm milk, should be administered as copiously as possible, and vomiting provoked by tickling the fauces with a feather. Clysters of a similar nature may be also employed. Many persons have escaped death by having taken the poison mixed with rich soups; and it is well known, that when it is prescribed as a medicine, it acts most beneficially when given soon after a meal. These facts have led to the prescription of butter and oils; the use of which is, however, not advisable, as they screen the arsenical particles from more proper menstrua, and even appear to aggravate its virulence. Morgagni, in his great work on the seats and causes of disease, states, that at an Italian feast the dessert was purposely sprinkled over with arsenic instead of flour. Those of the guests who had previously ate and drank little, speedily perished; those who had their stomachs well filled, were saved by vomiting. He also mentions the case of three children who ate a vegetable soup poisoned with arsenic. One of them, who took only two spoonfuls, had no vomiting, and died; the other two, who had eaten the rest, vomited, and got well. Should the poisoned patient be incapable of vomiting, a tube of caoutchouc, capable of being attached to a syringe, may be had recourse to. The tube first serves to introduce the drink, and to withdraw it after a few instants.

The following tests of arsenic and corrosive sublimate have been lately proposed by Brugnatelli: Take the starch of wheat boiled in water until it is of a proper consistence, and recently prepared; to this add a sufficient quantity of iodine to make it of a blue colour; it is afterwards to be diluted with pure water until it becomes of a beautiful azure. If to this, some drops of a watery solution of arsenic be added, the colour changes to a reddish hue, and finally vanishes. The solution of corrosive sublimate poured into iodine and starch, produces almost the same change as arsenic; but if to the fluid acted on by the arsenic we add some drops of sulphuric acid, the original blue colour is restored with more than its original brilliancy, while it does not restore the colour to the corrosive sublimate mixture."—*Ure's Chem. Dict.*

ARTEMI'SIA. (From a queen of that name, who first used it; or from Αρτεμις, Diana: because it was formerly used in the diseases of women, over whom she presided.) The name of a genus of plants in the Linnæan system. Class, *Syngenesia*; Order, *Polygamia superflua*.

ARTEMISIA ABROTANUM. The systematic name for the *Abrotanum* of the pharmacopœias. *Abrotanum mas; Adonion; Adonium; Abrathan.* Common southernwood. *Artemisia—foliis setaceis ramosissimis* of Linnæus. A plant possessed of a strong, and, to most people, an agreeable smell; a pungent, bitter, and somewhat nauseous taste. It is supposed to stimulate the whole system, but more particularly the uterus. It is very rarely used unless by way of fomentation, with which intention the leaves are directed.

ARTEMISIA ABSINTHIUM. The systematic name for the *Absinthium vulgare* of the pharmacopœias. Common wormwood. Falsely called in our markets *Absinthium Romanum*, or Roman wormwood. *Absinthium Ponticum* of Dioscorides and Pliny, according to *Murray*. *Artemisia—foliis compositis multifidis floribus subglobosis pendulis; receptaculo villoso* of Linnæus. This plant is a native of Britain, and grows about rubbish, rocks, and sides of roads. The leaves of wormwood have a strong disagreeable smell: their taste is nauseous, and so intensely bitter as to be proverbial. The flowers are more aromatic and less bitter than the leaves, and the roots discover an aromatic warmth, without bitterness. This species of wormwood may be considered the principal of the herbaceous bitters. Its *virtus*, in the words of Bergius, is antiputredinosa, antacida, anthelmintica, resolvents, tonica, spasmodica. And although it is now chiefly employed with a view to the two last-mentioned qualities, yet we are told of its good effects in a great variety of diseases, as intermittent fevers, hypochondriasis, obstructions of the liver and spleen, gout, calculi, scurvy, dropsy, worms, &c. Cullen thinks it is possessed of a narcotic power, and that there is in every bitter, when largely employed, a power of destroying the sensibility and irritability of the nervous system.

Externally, wormwood is used in discutient and antiseptic fomentations. This plant may be taken in powder, but it is more commonly preferred in infusion. The Edinburgh Pharmacopœia directs a tincture of the flowers, which is, in the opinion of Dr. Cullen, a light and agreeable bitter, and, at the same time, a strong impregnation of the wormwood.

ARTEMISIA CHINENSIS. Mugwort of China. *Moxa Japonica; Musia pattræ.* A soft lanuginous substance, called *Moxa*, is prepared in Japan, from the young leaves of this species of mugwort, by beating them when thoroughly dried, and rubbing them betwixt the hands, till only the fine fibres are left. Moxa is celebrated in the eastern countries for preventing and curing many disorders, by being burnt on the skin; a little cone of it laid upon the part, previously moistened, and set on fire on the top, burns down with a temperate and glowing heat, and produces a dark-coloured spot, the ulceration of which is promoted by putting a little garlic, and the ulcer is either healed up when the eschar separates, or kept running for a length of time, as different circumstances may require.

ARTEMISIA GLACIALIS. Mountain wormwood. This is found on Alpine situations, and has similar virtues to common wormwood.

ARTEMISIA JUDAICA. The systematic name for the *Santonicum* of the pharmacopœias, according to some botanists. See *Artemisia santonica.*

ARTEMISIA MARITIMA. The systematic name for the *Absinthium maritimum* of the pharmacopœias. Sea wormwood, falsely called in our markets, Roman wormwood. *Artemisia—foliis multipartitis, tomentosis; racemis cernuis; flosculis fœmineis ternis* of Linnæus. This plant grows plentifully about the sea-shore, and in salt marshes. The specific differences between it and the common wormwood, *artemisia absinthium*, are very evident. Its taste and smell are considerably less unpleasant than those of the common wormwood, and even the essential oil, which contains the whole of its flavour concentrated, is somewhat less ungrateful, and the watery extract somewhat less bitter than those of the common wormwood. Hence it is preferred, in those cases where the *Artemisia absinthium* is supposed to be too unpleasant for the stomach. A conserve of the tops of this plant was directed by the London Pharmacopœia.

ARTEMISIA PONTICA. The systematic name for the *Absinthium ponticum*, or Roman wormwood, not now used medicinally.

ARTEMISIA RUPESTRIS. The systematic name for the *genipi album* of the pharmacopœias. *Artemisia—foliis pinnatis; caulibus adscendentibus; floribus globosis, cernuis; receptaculo papposo.* It has a grateful smell, and is used in some countries in the cure of intermittents and obstructed catamenia.

ARTEMISIA SANTONICA. *Absinthium santonicum Alexandrinum; Sementina; Absinthium seriphium Ægyptium; Schebu Arabum; Zedoariæ semen; Xantolina; Lumbricorum semina; Cina; Semen contra; Semen sanctum; Artemisia Judaica.* The Tartarian southernwood or wormseed. *Artemisia:—foliis caulinis lineraribus, pinnato-multifidis; ramis indivisis; spicis secundis reflexis; floribus quinquefloris* of Linnæus. The seeds are small, light, and oval, composed of a number of thin membraneous coats of a yellowish-green colour, with a cast of brown, easily friable, upon being rubbed between the fingers, into a fine chaffy kind of substance. They are brought from the Levant; have a moderately strong and not agreeable smell, somewhat of the wormwood kind, and a very bitter subacrid taste. Their virtues are extracted both by watery and spirituous menstrua. They are esteemed to be stomachic, emmenagogue, and anthelmintic; but it is especially for the last-mentioned powers that they are now administered, and from their efficacy in this way they have obtained the name of wormseed. To adults the dose in substance is from one to two drachms, twice a day. Lewis thinks that the spirituous extract is the most eligible preparation of the santonicum, for the purposes of an anthelmintic.

ARTEMISIA VULGARIS. Mugwort. This plant, *Artemisia—foliis pinnatifidis, planis, incisis, subtus tomentosis; racemis simplicibus, recurvatis; floribus radio quinquefloro* of Linnæus, is slightly bitter, and, although in high esteem in former days, is now almost wholly forgotten.

ARTEMO'NIUM. (From *Artemon*, its inventor.) A collyrium, or wash for the eyes.

ARTE'RIA. (*Arteria, æ.* f.; from αηρ, air, and τηρεω, to keep; so called because the ancients believed they contained air only.) See *Artery.*

ARTERI'ACA. (From αρτήρια, an artery.) Medicines formerly used against disorders of the aspĕra arteria, or trachea.

ARTERIÆ ADIPOSÆ. The arteries which secrete the fat about the kidneys are so called. They are branches of the capsular and diaphragmatic, renal, and spermatic arteries.

ARTERIÆ VENOSÆ. The four pulmonary veins were so called by the ancients.

ARTERIO'SUS DUCTUS. See *Ductus arteriosus.*

ARTERIO'TOMY. (*Arteriotomia, æ.* f.; from αρτηρια, an artery, and τεμνω, to cut.) The opening of an artery. This operation is frequently performed on the temporal artery.

A'RTERY. *Arteria.* A membraneous pulsating canal, that arises from the heart and gradually becomes less as it proceeds from it. Arteries are composed of three membranes; a common, or external; a muscular; and an internal one, which is very smooth. They are only two in number, the pulmonary artery, and the aorta, and these originate from the heart; the pulmonary artery from the right ventricle, and the aorta from the left: the other arteries are all branches of the aorta. Their termination is either in the veins, or in capillary exhaling vessels, or they anastomose with one another. It is by their means that the blood is carried from the heart to every part of the body, for nutrition, preservation of life, generation of heat, and the secretion of the different fluids. The action of the arteries, called the pulse, corresponds with that of the heart, and is effected by the contraction of their muscular, and great elasticity of their outermost coat.

A table of the Arteries.

All the arteries originate from the pulmonary artery and the aorta.

The *pulmonary artery* emerges from the right ventricle of the heart, soon divides into a right and left branch, which are distributed by innumerable ramifications through the lungs.

The *aorta* arises from the left ventricle of the heart, and supplies every part of the body with blood, in the following order.

a. It first forms an *arch.*
b. It then descends along the spine; and,
c. It divides into the two *iliacs.*

a. The ARCH OF THE AORTA gives off three branches.

1. The *arteria innominata,* which divides into the *right carotid* and *right subclavian.*
2. The *left carotid.*
3. The *left subclavian.*

I. The *carotids* are divided into *external* and *internal.*

The *external carotids* give off,

1. The *thyroid,*
2. The *lingual,*
3. The *labial,*
4. The *inferior pharyngeal,*
5. The *occipital,*
6. The *posterior auris,*
7. The *internal maxillary,* from which the *spinous artery of the dura mater,* the *lower maxillary,* and *several branches about the palate and orbit* arise,
8. The *temporal.*

The *internal carotid* affords,

1. The *ophthalmic,*
2. The *middle cerebral,*
3. The *communicans,* which inosculates with the *vertebral.*

II. The *subclavians* give off the following branches:

1. The *internal mammary,* from which the *thymic, comes phrenici, pericardiac,* and *phrenico-pericardiac arteries* arise,
2. The *inferior thyroid,* which gives off the *tracheal, ascending thyroid,* and *transversalis humeri,*
3. The *vertebral,* which proceeds within the vertebræ, and forms within the cranium the *basilary artery,* from which the *anterior cerebelli,* the *posterior cerebri,* and *many branches about the brain* are given off,
4. The *cervicalis profunda,*
5. The *cervicalis superficialis,*
6. The *superior intercostal,*
7. The *supra-scapular.*

As soon as the subclavian arrives at the armpit, it is called the *axillary artery;* and when the latter reaches the arm, it is called the *brachial.*

The *axillary artery* gives off,

1. *Four mammary arteries,*
2. The *sub-scapular,*
3. The *posterior circumflex,*
4. The *anterior circumflex,* which ramify about the shoulder-joint.

The *brachial artery* gives off,

1. *Many lateral branches,*
2. The *profunda humeri superior,*
3. The *profunda humeri inferior,*
4. The *great anastomosing artery,* which ramifies about the elbow-joint.

The *brachial artery* then divides, about the bend of the arm, into the *ulnar* and *radial arteries,* which are ramified to the ends of the fingers.

The *ulnar artery* gives off,

1. *Several recurrent branches,*
2. The *common interosseal,* of which the *dorsal ulnar,* the *palmaris profunda,* the *palmary arch,* and the *digitals,* are branches.

The *radial artery* gives off,

1. The *radial recurrent,*
2. The *superficialis volæ,* and then divides into the *palmaris profunda,* and the *digitals.*

b. The DESCENDING AORTA gives off,

In the breast,

1. The *bronchial,*
2. The *œsophageal,*
3. The *intercostals,*
4. The *inferior diaphragmatic.*

Within the abdomen,

1. The *cœliac,* which divides into three branches:
    1. The *hepatic,* from which are given off, before it reaches the liver,
        α. The *duodeno-gastric,* which sends off the *right gastro-epiploic* and the *pancreatico-duodenal,*
        β. The *pylorica superior hepatica;*
    2. The *coronaria ventriculi,*
    3. The *splenic,* which emits the *great* and *small pancreatics,* the *posterior gastric,* the *left gastro-epiploic,* and the *vasa brevia;*
2. The *superior mesenteric,*
3. The *emulgents,*
4. The *spermatics,*
5. The *inferior mesenteric,*
6. The *lumbar arteries,*
7. The *middle sacral.*

c. The aorta then bifurcates into the ILIACS, each of which divide into *external* and *internal.*

The *internal iliac,* called also *hypogastric,* gives off,

1. The *lateral sacrals,*
2. The *gluteal,*
3. The *ischiatic,*
4. The *pudica,* from which the *external hæmorrhoidal,* the *perineal,* and the *arteriæ penis* arise,
5. The *obturatory,*

The *external iliac* gives off, in the groin,

1. The *epigastric,*
2. The *circumflexia iliaca;*

It then passes under Poupart's ligament, and is called the *femoral artery;* and sends off,

1. The *profunda*,
2. The *ramus anastomoticus magnus*, which runs about the knee-joint;

Having reached the ham, where it gives off some small branches, it is termed the *popliteal*. It then divides into the *anterior* and *posterior tibial*.

The *tibialis antica* gives off,

1. The *recurrent*,
2. The *internal malleolar*,
3. The *external malleolar*,
4. The *tarsal*,
5. The *metatarsal*,
6. The *dorsalis externa halicis*.

The *posterior tibial* sends off,

1. The *nutritia tibiæ*,
2. *Many small branches*,
3. The *internal plantar*,
4. The *external plantar*, from which an *arch* is formed, that gives off the *digitals of the toes*.

ARTHANI'TA. (From αρτος, bread; because it is the food of swine.) The herb sowbread. See *Cyclamen Europeum*.

ARTHRE'MBOLUS. (From αρθρον, a joint, and εμβαλλω, to impel.) An instrument for reducing luxated bones.

ARTHRI'TIC. (*Arthriticus*; from αρθριτις, the gout.) Pertaining to the gout.

ARTHRITICA HERBA. The *Ægopodium podagraria*, and several other plants, were so called.

ARTHRI'TIS. (*Arthritis, tidis.* fœm.; from αρθρον, a joint: because it is commonly confined to the joints.) The gout. Dr. Cullen, in his Nosology, gives it the name of *podagra*, because he considers the foot to be the seat of idiopathic gout. It is arranged in the class *Pyrexiæ*, and order *phlegmasiæ*, and is divided into four species, the regular, atonic, retrocedent, and misplaced. See *Podagra*.

ARTHROCA'CE. (From αρθρον, a joint, and κακη, a disease.) An ulcer of the cavity of the bone.

ARTHRO'DIA. *Arthrodia, æ.* f.; from αρθροω, to articulate.) A species of *diarthrosis*, or moveable connexion of bones, in which the head of one bone is received into the superficial cavity of another, so as to admit of motion in every direction, as the head of the humerus with the glenoid cavity of the scapula.

ARTHRODY'NIA. (*Arthrodynia, æ.* f.; from αρθρον, a joint, and οδυνη, pain.) Pain in a joint. It is one of the terminations of acute rheumatism. See *Rheumatismus*.

ARTHROPUO'SIS. (*Arthropuosis, is.* f.; from αρθρον, a joint, and πυον, pus.) *Arthropyosis*. A collection of pus in a joint. It is however frequently applied to other affections. See *Lumber abscess*.

ARTHROSIA. (*Arthrosiæ*; from αρθροω, to articulate: whence *arthrosis*, *arthrites*.) The name of a genus of disease in Good's new classification, which embraces rheumatism, gout, and white swelling. See *Nosology*.

ARTHRO'SIS. (From αρθροω, to articulate, or join together.) Articulation.

ARTICHOKE. See *Cinara scolymus*.

Artichoke, French. See *Cinara scolymus*.

Artichoke, Jerusalem. See *Helianthus tuberosus*.

ARTICULA'R. (*Articularis*; from *articulus*, a joint.) Belonging to a joint.

ARTICULARIS MORBUS. A name given to a disease which more immediately infests the *articuli*, or joints. The morbus articularis is synonymous with the Greek word arthritis, and our gout.

ARTICULARIS VENA. A branch of the basilic vein is so called because it passes under the joint of the shoulder.

ARTICULATION. (*Articulatio*; from *articulus*, a joint.) The skeleton is composed of a great number of bones, which are all so admirably constructed, and with so much affinity to each other, that the extremity of every bone is perfectly adjusted to the end of the bone with which it is connected; and this connexion is termed their articulation. Anatomists distinguish three kinds of articulation; the first they name *Diarthrosis*; the second, *Synarthrosis*; and the third, *Amphiarthrosis*; which see, under their respective heads.

ARTICULA'TUS. Articulate; jointed A term applied to roots, stems, leaves, &c. when they are apparently formed of distinct pieces united as if one piece grew out of another, so as to form a jointed, but connected whole: in the *Radix articulata*, radicles shoot out from each joint, as in the *Oxalis acetosella*, wood sorrel. The *Caulis articulata* is exemplified in the *Cactus flagelliformis* and *Lathyrus sylvestris*; the *Cactus opuntia* and *Cactus ficus indica* have articulate leaves. The *Oxalis acetosella* articulate leafstalks.

ARTICULUS. (From *artus*, a joint; from αρθρον.) 1. A joint. See *Articulation*.

2. Botanists apply this term to that part of the stalk of grasses which is intercepted, or lies between two knots; and also to the knot itself.

ARTI'SCUS. (From αρτος, bread.) A troch; so called because it is made like a little loaf.

ARTO'CREAS. (From αρτος, bread, and κρεας, flesh.) A nourishing food, made of bread and various meats, boiled together.—*Galen*.

ARTO'GALA. (From αρτος, bread, and γαλα, milk.) A cooling food made of bread and milk. A poultice.

ARTO'MELI. (From αρτος, bread, and μελι, honey.) A cataplasm made of bread and honey. —*Galen*.

A'RUM. (*Arum, i.* n.; from the Hebrew word *jarôn*, which signifies a dart; so named because its leave sare shaped like a dart; or from αρα, injury.) 1. The name of a genus of plants in the Linnæan system. Class, *Gynandria*; Order, *Polyandria*.

2. The pharmacopœial name of the common arum. See *Arum maculatum*.

ARUM DRACUNCULUS. The systematic name of the plant called, in English, dragon's wort, and many-leaved arum; *Dracunculus polyphyllus*; *Colubrina dracontia*; *Serpentaria gallorum*; *Erva de Sancta Maria*; *Gigarus serpentaria*; *Arum polyphyllum*. The roots and leaves of this plant are extremely acrimonious, more so than the *Arum maculatum*, with which it agrees in medicinal virtues.

ARUM MACULATUM. The systematic name for common arum, or wake-robin; the *arum* of the pharmacopœias. *Arum—acaule*; *foliis hastatis, integerrimis*; *spadice clavato* of Linnæus. Common arum or wake-robin. The root is the medicinal part of this plant, which, when recent, is very acrimonious; and, upon being chewed, excites an intolerable sensation of burning and prickling in the tongue, which continues for several hours. When cut in slices and applied to the skin, it has been known to produce blisters. This acrimony, however, is gradually lost by drying, and may be so far dissipated by the application of heat, as to leave the root a bland farinaceous aliment. In this state, it has been made into a wholesome bread. It has also been prepared as starch. Its medicinal quality, therefore, resides wholly in the active volatile matter, and consequently the powdered root must lose much of its power, on being long kept. Arum is certainly a powerful stimulant, and, by promoting the secretions, may be advantageously employed in cachectic and chlorotic cases in rheumatic affections, and in various other complaints of phlegmatic and torpid constitutions; but more especially in a weakened or relaxed state of the stomach, occasioned by the prevalence of viscid mucus. If this root is given in powder, great care should be taken that it be young and newly dried, when it may be used in the dose of a scruple, or more, twice a day; but in rheumatisms, and other disorders requiring the full effect of this medicine, the root should be given in a recent state; and, to cover the insupportable pungency it discovers on the tongue, Dr. Lewis advises us to administer it in the form of emulsion, with gum-arabic and spermaceti, increasing the dose from ten grains to upwards of a scruple, three or four times a day. In this way, it generally occasioned a sensation of slight warmth about the stomach, and afterwards, in the remoter parts, manifestly promoted perspiration, and frequently produced a plentiful sweat. Several obstinate rheumatic pains were removed by this medicine. The root answers quite as well as garlic for cataplasms, to be applied on the feet in deliriums. The London College, in their Pharmacopœia, 1788, ordered a conserve, in the proportion of half a pound of the fresh root to a pound and a half of double refined sugar, beat together in a mortar, which appears to be one of the best forms of exhibiting arum, as its virtues are destroyed by drying, and are not extracted by any menstruum. It may be given to adults in doses of a drachm.

ARUNDINACEUS. (From *arundo*, a reed.) Arundinaceous or reed-like.

ARUNDINACEÆ PLANTÆ. Arundinaceous plants. A name given to a class of plants by Ray, from their appearance.

ARUNDO. (*Arundo, inis*, f.; supposed to be derived from *areo*, because it soon becomes dry.) The name of a genus of plants in the Linnæan system. Class, *Triandria*; Order, *Digynia*.

ARUNDO BAMBOS. The bamboo plant. The young shoots of this plant are prepared by the natives of both Indies with vinegar, garlic, pepper, &c. into excellent pickles, which promote the appetite, and assist digestion. A substance called *Tabasheer* or *Tabachir*, which is a concretion of the liquor in the cavities of the cane, and extracted at certain seasons, is much esteemed as a medicine by the orientalists.

ARUNDO SACCHARIFERA. The name of the sugar-cane. See *Saccharum officinale*.

ARYTÆ'NO. Belonging to the arytænoid cartilage. Some muscles are so named because they are connected with this cartilage: they have also the terminal name of the part they go to; as *ærytæno-epiglottideus*.

ARYTÆNO-EPIGLOTTIDEUS. A muscle of the epiglottis. *Arytæno-Epiglottici* of Winslow. It is composed of a number of fibres running between the arytænoid cartilage and epiglottis. It pulls the side of the epiglottis towards the external opening of the glottis, and when both act, they pull it close upon the glottis.

ARYTÆNOI'D. (*Arytænoideus* and *Arytænoides*; from αρυλαινα, a funnel, and ειδος, shape.) The name of some parts, from their being funnel-shaped.

ARYTÆNOID CARTILAGE. *Cartilago arytænoidea.* The name of two cartilages of the larynx. See *Larynx.*

ARYTÆNOIDE'US. Applied to some muscles, vessels, nerves, &c.

ARYTÆNOIDEUS MAJOR. See *Arytænoideus transversus.*

ARYTÆNOIDEUS MINOR. See *Arytænoideus obliquus.*

ARYTÆNOIDEUS OBLIQUUS. A muscle of the glottis. *Arytænoideus minor* of Douglas. It arises from the base of one arytænoid cartilage, and crossing its fellow, is inserted near the tip of the other arytænoid cartilage. This muscle is occasionally wanting; but when present, and both muscles act, their use is to pull the arytænoid cartilages towards each other.

ARYTÆNOIDEUS TRANSVERSUS. An azygos, or single muscle of the glottis. *Arytænoideus major* of Douglas. It arises from the side of one arytænoid cartilage, from near its articulation with the cricoid to near its tip. The fibres run across, and are inserted in the same manner into the other arytænoid cartilage. Its use is to shut the glottis, by bringing the two arytænoid cartilages, with their ligaments, nearer to each other.

ASAFŒ'TIDA. (*Asafœtida, æ.* f.; from the Hebrew word *asa*, to heal.) See *Ferula.*

ASA'PHATUM. (From α, neg. and σαφης, clear, so called by reason of their minuteness.) An intercutaneous disorder, generated in the pores, like worms with black heads.

ASA'PHIA. (From α, neg. and σαφης, clear.) A defect in utterance or pronunciation.

ASARABACCA. See *Asarum Europæum.*

A'SARUM. (*Asarum, i.* n.; from α, neg. and σαιρω, to adorn; because it was not admitted into the ancient coronal wreaths.) 1. The name of a genus of plants in the Linnæan system. Class, *Dodecandria*; Order, *Monogynia.*

2. The pharmacopœial name of the asarabacca. See *Asarum Europæum.*

ASARUM EUROPÆUM. The systematic name of the asarabacca of the shops. *Nardus montana; Nardus rustica; Asarum—foliis reniformibus, obtusis, binis* of Linnæus. This plant is a native of England, but not very common. Its leaves are extremely acrid, and are occasionally used, when powdered, as a sternutatory. For this purpose, the leaves, as being less acrid than the roots, are preferred, and in moderate doses not exceeding a few grains, snuffed up the nose, for several evenings, produce a pretty large watery discharge, which continues for several days together, by which headache, toothache, ophthalmia, and some paralytic and soporific complaints have been effectually relieved.

Prior to the introduction of ipecacuanha, the leaves and root of this plant were frequently employed on account of their emetic power: the dose of the dried leaves was 20 grains; of the dried roots 10 grains. As they were occasionally violent in their operation, they have fallen into disuse.

ASARUM HYPOCISTIS. A parasitical plant which grows in warm climates, from the roots of the *Cistus.* The juice, *succus hypocistidis*, is a mild astringent, of no particular smell nor flavour. It has fallen into disuse.

ASBESTOS. *Asbestus.* A mineral of which there are five varieties, all more or less flexible and fibrous. 1. *Amianthus* occurs in very long, fine, flexible, elastic fibres, of a white, greenish, or reddish colour. It is somewhat unctuous to the touch, has a silky or pearly lustre, and is slightly translucent. Sectile; tough; sp. grav. from 1 to 2.3.

The ancients manufactured cloth out of the fibres of asbestos, for the purpose, it is said, of wrapping up the bodies of the dead, when exposed on the funeral pile. Several moderns have likewise succeeded in making this cloth, the chief artifice of which seems to consist in the admixture of flax and a liberal use of oil; both which substances are afterwards consumed by exposing the cloth for a certain time to a red heat. Although the cloth of asbestos, when soiled, is restored to its primitive whiteness by heating in the fire, it is found, nevertheless, by several authentic experiments, that its weight diminishes by such treatment. The fibres of asbestos, exposed to the violent heat of the blowpipe, exhibit slight indications of fusion; though the parts, instead of running together, moulder away, and part fall down, while the rest seem to disappear before the current of air. Ignition impairs the flexibility of asbestos in a slight degree.

2. *Common Asbestos* occurs in masses of fibres of a dull greenish colour, and of a somewhat pearly lustre. Fragments splintery. It is scarcely flexible, and greatly denser than amianthus. It is more abundant than amianthus, and is found usually in serpentine, as at Portsoy, the Isle of Anglesea, and the Lizard in Cornwall. It was found in the limestone of Glentilt, by Dr. M'Culloch, in a pasty state, but it soon hardened by exposure to air.

3. *Mountain Leather* consists not of parallel fibres like the preceding, but interwoven and interlaced so as to become tough. When in very thin pieces it is called *mountain paper*. Its colour is yellowish-white, and its touch meagre. It is found at Wanlockhead, in Lanarkshire. Its specific gravity is uncertain.

4. *Mountain Cork*, or *Elastic Asbestos*, is, like the preceding, of an interlaced fibrous texture; is opaque, has a meagre feel and appearance, not unlike common cork, and like it, too, is somewhat elastic. It swims on water. Its colours are white, gray, and yellowish-brown; receives an impression from the nail; very tough; cracks when handled, and melts with difficulty before the blowpipe.

5. *Mountain Wood*, or *Ligniform asbestos*, is usually massive, of a brown colour, and having the aspect of wood. Internal lustre glimmering. Soft, sectile, and tough; opaque; feels meagre; fusible into a black slag. Sp. grav. 2.0. It is found in the Tyrol; Dauphiny; and in Scotland, at Glentilt, Portsoy, and Kildrumie.

ASCALONI'TES. A species of onion.

ASCA'RIDES. The plural of *ascaris*.

A'SCARIS. (*Ascaris, idis;* from ασκεω, to move about; so called from its continued troublesome motion.) The name of a genus of intestinal worms. There are several species of this genus. Those which belong to the human body are:—

1. *Ascaris vermicularis*, the thread or maw worm, which is very small and slender, not exceeding half an inch in length; it inhabits the rectum.

2. *Ascaris bumbricoides*, the long and round worm, which is a foot in length, and about the breadth of a goose-quill.

ASCE'NDENS. (From *ad* and *scando*, to ascend.) *Adscendens*. Ascending. Applied to muscles, leaves, stalks, &c. from their direction; as *musculus obliquus ascendens, folium ascendens, caulis ascendens*, the leaves of the *geranium vitifolium*, and stems of the *hedysarum onobrychis*, &c.

ASCENDENS OBLIQUUS. See *Obliquus internus abdominus.*

A'SCIA. An axe or chisel. A simple bandage; so called from its shape in position.—*Galen.*

ASCIDIATUS. (From *ascidium.*) Ascidiate or pitcherform: a term applied to a leaf and other parts of plants which are so formed; the *folium ascidiatum* is seen in the *Nepenthes Distillatoria*, and in *Saracenia.*

ASCIDIUM. (From ασκιδιον, a small bottle.) The pitcher. A term introduced by Willdenow into botany to express a hollow foliaceous appendage, resembling a small pitcher. It is of rare occurrence, but has been found as a *caulinar, foliar*, and a *peduncular* or floral appendage.

1. The *caulinar* belongs to the Austalasian plant *Cephalotus follicularis.*

2. The *foliar* is peculiar to the genus *Nepenthes.*

3. The *peduncular* on the *Surubea quianensis.*

ASCI'TES. (*Ascites, æ.* m.; from ασκος, a sack, or bottle; so called from its bottle-like protuberancy.) Dropsy of the belly. A tense, but scarcely elastic, swelling of the abdomen from accumulation of water. Cullen ranks this genus of disease in the class *Cachexiæ*, and order, *Intumescentiæ*. He enumerates two species:

1. *Ascites abdominalis*, when the water is in the cavity of the peritonæum, which is known by the equal swelling of the parietes of the abdomen.

2. *Ascites saccatus*, or encysted dropsy, in which the water is encysted, as in the ovarium; the fluctuation is here less evident, and the swelling is at first partial.

Ascites is often preceded by loss of appetite, sluggishness, dryness of the skin, oppression at the chest, cough, diminution of the natural discharge of urine, and costiveness. Shortly after the appearance of these symptoms, a protuberance is perceived in the hypogastrium, which extends gradually, and keeps on increasing, until the whole abdomen becomes at length uniformly swelled and tense. The distension and sense of weight, although considerable, vary somewhat according to the posture of the body, the weight being felt the most on that side on which the patient lies, whilst, at the same time, the distention becomes somewhat less on the opposite side. In general, the practitioner may be sensible of the fluctuation of the water, by applying his left hand on one side of the abdomen, and then striking on the other side with his right. In some cases, it will be obvious to the ear. As the collection of water becomes more considerable, the difficulty of breathing is much increased, the countenance exhibits a pale and bloated appearance, an immoderate thirst, the skin is dry and parched, and the urine is very scanty, thick, high coloured, and deposits a lateritious sediment. With respect to the pulse, it is variable, being sometimes considerably quickened, and, at other times, slower than natural. The principal difficulty, which prevails in ascites, is the being able to distinguish, with certainty, when the water is in the cavity of the abdomen, or when it is in the different states of encysted dropsy. To form a just judgment, we should attend to the following circumstances:—When the preceding symptoms gave suspicion of a general hydropic diathesis; when, at the same time, some degree of dropsy appears in other parts of the body; and when, from its first appearance, the swelling has been equally diffused over the whole belly, we may generally presume that the water is in the cavity of the abdomen. But when an ascites has not been preceded by any remarkable cachectic state of the system, and when, at its beginning, the tumour and tension had appeared in one part of the belly more than another, there is reason to suspect an encysted dropsy. Even when the tension and tumour of the belly have become general, yet, if the system or the body in general appear to be little affected; if the patient's strength be little impaired; if the appetite continue pretty entire, and the natural sleep be little interrupted; if the menses in females continue to flow as usual; if there be yet no anasarca, or, though it may have already taken place, if it be still confined to the lower extremities, and there be no leucophlegmatic paleness or sallow colour in the countenance; if there be no fever, nor so much thirst and scarcity of urine as occur in a more general affection: then according as more of these different circumstances take place, there will be the stronger grounds for supposing the ascites to be of the encysted kind. The encysted form of the disease scarcely admits of a perfect cure, though its progress to a fatal termination is generally very slow; and the peritonæal dropsy is mostly very obstinate, depending usually on organic disease in the liver, or other abdominal viscera. The plan of treatment agrees very much with that of *anasarca;* which see. The operation of paracentesis should only be performed where the distension is very great, and the respiration or other important functions impeded; and it will often be better not to draw off the whole of the fluid at once; great care must be taken, too, to keep up sufficient pressure by a broad bandage over the abdomen; for even fatal syncope has arisen from the neglect of this. The contraction of the muscles will be promoted by friction. Cathartics are found more decidedly beneficial than in anasarca, where the bowels will bear their liberal use. Diuretics too are of great importance in the treatment; and, among other means of increasing the flow of urine, long-continued gentle friction of the abdomen with oil has been sometimes very successful, probably by promoting absorption in the first instance; the only use of the oil seems to be that the friction is thereby better borne. In cases where visceral obstructions have led to the effusion, these must be removed, before a cure can be accomplished: and for this purpose mercury is the remedy most to be depended upon, besides that, in combination with squill, or digitalis, it will often prove powerfully diuretic. Tonic medicines, a nutritious diet, and, if the complaint appears giving way, such exercise as the patient can take, without fatigue, with other means of improving the general health, ought not to be neglected.

ASCLEPI'ADES, a celebrated physician, born at Prusa, in Bithynia, who flourished somewhat before the time of Pompey. He originally taught rhetoric, but not meeting with success, applied himself to the study of medicine, in which he soon became famous from the novelty of his theory and practice. He supposed disease to arise from the motion of the particles of the blood and other fluids being obstructed by the straitness of the vessels, whence pain, fever, &c. ensued. He deprecated the use of violent remedies, as emetics and purgatives, but frequently employed glisters, when costiveness attended. In fevers, he chiefly relied on a complete abstinence from food or drink for three days or more; but when their violence abated, allowed animal food and wine. In pleurisies, and other complaints attended with violent pain, he prescribed bleeding; but in those of a chronic nature, depended principally on abstinence, exercise, baths, and frictions. None of his works remain at present. He is said to have pledged his reputation on the preservation of his own health, which he retained to a great age, and died at length from a fall.

ASCLE'PIAS. (From *Asclepias ădis.* f.; so named after its discoverer; or from *Æsculapius*, the god of medicine.) The name of a genus of plants in the Linnæan system. Class, *Pentandria;* Order, *Digynia.*

Asclepias syriaca. Syrian dog's bane. This plant is particularly poisonous to dogs, and also to the human species. Boiling appears to destroy the poison in the young shoots, which are then said to be esculent, and flavoured like asparagus.

Asclepias vincetoxicum. The systematic name for the *vincetoxicum* of the pharmacopœias. *Hermidinaria; Asclepias.* Swallow-wort; Tame poison. The root of this plant smells, when fresh, somewhat of valerian; chewed, it imparts at first a considerable sweetness, which is soon succeeded by an unpleasant subacrid bitterness. It is given in some countries in the cure of glandular obstructions.

Ascle'pios. (From *Asclepias*, its inventor.) A dried smegma and collyrium described by Galen.

Asco'ma. (From ασκος, a bottle.) The eminence of the pubes at the years of maturity, so called from its shape.

ASCYROIDEÆ. A name given by Scoipoli to a class of plants which resemble the *Ascyrum*, St. Peter's worth.

A'sef. A pustule like a millet seed.

A'segon. *Ascgen; Asogen.* Dragon's blood. See *Calamus rotang.*

ASE'LLIUS, Gaspar, of Cremona, born about the year 1580, taught anatomy at Paris with great reputation. In 1622, he discovered the lacteals in a dog opened soon after a meal, and noticed their valves, but supposed they went to the liver. These vessels, he candidly observes, had been mentioned by some of the earliest medical writers, but not described, nor their function stated; and not being noticed by any modern anatomist previously, the discovery is properly attributed to him. His death took place four years after, subsequent to which his dissertation on the subject was published by his friends.

ASH. See *Fraxinus excelsior.*

Asiaticum balsamum. Balm of Gilead.

A'SINUS. The ass. A species of the genus *Equus.* Its milk is preferred to cow's and other kinds of milk, in phthisical cases, and where the stomach is weak; as containing less oleaginous particles, and being more easily converted into chyle. See *Milk, Asses.*

Asini'num lac. Asses' milk.

Asi'ti. (From α, neg. and σιτος, food.) *Asitia.* Those are so called who take no food, for want of appetite.

A'sjogam. (Indian.) A tree growing in Malabar and the East Indies, the juice of which is used against the colic.

Aso'des. (From αδω, to nauseate.) A nausea or loathing, or a fever with much sense of heat and nausea.—*Aretæus.*

Aspadia'lis. A suppression of urine from an imperforated urethra.

Aspalathum. See *Lignum aloes.*

ASPALATHUS. (From α, and σπαω, because the thorns were not easily drawn out of the wounds they made.) The name of a genus of plants in the Linnæan system. Class, *Diadelphia;* Order, *Decandria.*

Aspalathus canariensis. The systematic name of the rose-wood tree, or *lignum rhodium* of the ancients. An essential oil is obtained from the roots, which is used principally as a perfume;

but is an excellent cordial and carminative given internally. The best preparation is a tincture, made by macerating four ounces of the wood in a pint of rectified spirit.

ASPARAGIN. White transparent crystals, of a peculiar vegetable principle, which spontaneously form in asparagus juice which has been evaporated to the consistence of syrup. They are in the form of rhomboidal prisms, hard and brittle, having a cool and slightly nauseous taste. They dissolve, in hot water, but sparingly in cold water, and not at all in alcohol. On being heated, they swell and emit penetrating vapours, which affect the eyes and nose like wood-smoke. Their solution does not change vegetable blues; nor is it affected by hydro-sulphuret of potassa, oxalate of ammonia, acetate of lead, or infusion of galls. Lime disengages ammonia from it; though none is evolved by triturating it with potassa. The asparagus juice should be first heated to coagulate the albumen, then filtered and left to spontaneous evaporation for 15 or 20 days. Along with the asparagin crystals, others in needles of little consistency appear, analogous to *mannite*, from which the first can be easily picked out.—*Vauquelin and Robiquet. Annales de Chimie*, vol. lv. and *Nicholson's Journal*, 15.

ASPA'RAGUS. (*Asparagus*, *i.* m. Ασπαραγος, a young shoot, before it unfolds its leaves.) 1. The name of a genus of plants in the Linnæan system. Class, *Hexandria*; Order, *Monogynia*. Asparagus.

2. The pharmacopœial name of the sparage. See *Asparagus officinalis*.

ASPARAGUS OFFICINALIS. The systematic name of the asparagus, the root of which has been esteemed as a diuretic. It is mostly employed as a food, but it contains very little nourishment. A peculiar vegetable principle, called asparagin, has been found in this plant. See *Asparagin*.

ASPA'SIA. (From *α*, for *αμα*, together, and *σπαω*, to draw.) A constrictive medicine for the pudendum muliebre. *Capivac.*

ASPER. Rough. Applied to parts which are rough, as *linea aspera*, &c.

In the language of botany, *scaber* and *asper* are used synonymously.

ASPER CAULIS. *Caulis scaber.* Scabrous stem; is when it is thickly covered with papillæ which are not visible, but can be felt when running the finger along it; as in *Galium aperine*, *Lithospermum arvense*, *Centaurea*, *nigra*, &c.

ASPERA ARTERIA. (So called from the inequality of its cartilages.) See *Trachea*.

ASPERIFOLIÆ. (From *asper*, rough.) Rough-leaved plants. The name of a class and of an order of plants given by Boerhaave, Ray, Linnæus, &c.

ASPE'RULA. (A diminutive of *asper*, the seeds being rough.) The name of a genus of plants in the Linnæan system. Class, *Tetrandria*; Order. *Monogynia*.

ASPERULA ODORATA. The systematic name for the officinal *matrisylva*. Woodroof. It is a low umbelliferous plant, growing wild in woods and copses, and flowering in May. It hath an agreeable odour, which is much improved by moderate drying: the taste is a little austere. It imparts its flavour to vinous liquors; and is commended as a cordial and deobstruent remedy.

ASPHALTI'TIS. 1. A kind of trefoil.

2. The last vertebra of the loins.

ASPHALTUM. *Asphaltus.* This substance, likewise called *Bitumen Judaicum*, or Jews' Pitch, is a smooth, hard, brittle, black or brown substance, which breaks with a polish, melts easily when heated, and when pure burns without leaving any ashes. It is found in a soft or liquid state on the surface of the Dead Sea, but by age grows dry and hard. The same kind of bitumen is likewise found in the earth in other parts of the world; in China; America, particularly in the island of Trinidad; and some parts of Europe, as the Carpathian hills, France, Neufchatel, &c.

According to Neumann, the asphaltum of the shops is a very different compound from the native bitumen; and varies, of course, in its properties, according to the nature of the ingredients made use of in forming it. On this account, and probably from other reasons, the use of asphaltum, as an article of the materia medica, is totally laid aside.

The Egyptians used asphaltum in embalming, under the name of mumia mineralis, for which it is well adapted. It was used for mortar at Babylon.

ASPHO'DELUS. (*Asphodelus*, *i.* m. from *ασπις*, a serpent, and *δειλος*, fearful; because it destroys the venom of serpents: or from *σποδελος*, ashes, because it was formerly sown upon the graves of the dead.) 1. The name of a genus of plants in the Linnæan system. Class, *Hexandria*; Order, *Monogynia*.

2. The pharmacopœial name of the daffodil. See *Asphodelus ramosus*.

ASPHODELUS RAMOSUS. The systematic name for the officinal, or branched asphodel. *Asphodelus:—caulenudo; foliis enciformibus, carinatis, lævibus*, of Linnæus. The plant was formerly supposed to be efficacious in the cure of sordid ulcers. It is now wholly laid aside.

ASPHY'XIA. (*Asphyxia*, *æ.* f.; from *α*, priv. and *οφυξις*, a pulse.) The state of the body, during life, in which the pulsation of the heart and arteries cannot be perceived. There are several species of asphyxia enumerated by different authors. See *Syncope*.

ASPIDI'SCUS. (From *ασπις*, a buckler.) The spincter muscle of the anus was formerly so called from its shape.—*Cælius Aurelianus*.

ASPLE'NIUM. (*Asplenium*, *ii.* n.; from *α*, priv. and *σπλην*, the spleen; because it was supposed to remove disorders of the spleen.) The name of a genus of plants in the Linnæan system. Class, *Cryptogamia*; Order, *Filices*.

ASPLENIUM CETERACH. The systematic name of the herb spleenwort. Miltwaste. *Scolopendria vera; Dorodilla.* This small bushy plant, *Asplenium—frondibus pinnatifidis, lobis alternis confluentibus obtusis* of Linnæus, grows upon old walls and rocks. It has an herbaceous, mucilaginous, roughish taste, and is recommended as a pectoral. In Spain it is given, with great success, in nephritic and calculous diseases.

ASPLENIUM RUTA MURARIA. The systematic name for the *ruta muraria* of the pharmacopœias. It is supposed by some to possess specific virtues in the cure of ulcers of the lungs, and is exhibited in the form of decoction.

ASPLENIUM SCOLOPENDRIUM. The systematic name for the *scolopendrium* of the pharmacopœias. *Phillitis; Lingua cervina.* Harts-tongue. This indigenous plant, *Asplenium—frondibus simplicibus, cordato lingulatis, integerrimis; stipitibus hirsutis* of Linnæus: grows on most shady banks, walls, &c. It has a slightly astringent and mucilaginous sweetish taste. When fresh and rubbed, it imparts a disagreeable smell. Harts-tongue, which is one of the *five capillary* herbs, was formerly much used to strengthen the viscera, restrain hæmorrhages and alvine fluxes, and to open obstructions of the liver and spleen, and for the general purposes of demulcents and pectorals.

ASPLENIUM TRICHOMANES. The systematic name for the *trichomanes* of the pharmacopœias. Common maiden-hair or spleenwort. *Asplenium—frondibus pinnatis, pinnis subrotundis, crenatis* of Linnæus. This plant is admitted into the Edinburgh Pharmacopœia: the leaves have a mucilaginous, sweetish, subastringent taste, without any particular flavour: they are esteemed useful in disorders of the breast, being supposed to promote the expectoration of tough phlegm, and to open obstructions of the viscera.

ASS. See *Asinus.*

Ass's milk. See *Asinus.*

ASSABA. A shrub found on the coast of Guinea, the leaves of which are supposed to disperse buboes.

A'SSAC. (Arabian.) Gum ammoniacum.

ASSAFŒ'TIDA. See *Ferula assafœtida.*

A'SSALA. The nutmeg.

A'SSANUS. The name of an old weight, consisting of two drachms.

ASSARABA'CCA. See *Asarum Europeum.*

ASSA'RIUM. A Roman measure of twelve ounces.

ASSARTHRO'SIS. Articulation.

ASSAY. Essay. This operation consists in determining the quantity of valuable or precious metal contained in any mineral or metallic mixture, by analysing a small part thereof. The practical difference between the analysis and the assay of an ore, consists in this: The analysis, if properly made, determines the nature and quantities of all the parts of the compound; whereas the object of the assay consists in ascertaining how much of the particular metal in question may be contained in a certain determinate quantity of the material under examination. Thus, in the assay of gold or silver, the baser metals are considered as of no value or consequence; and the problem to be resolved is simply, how much of each is contained in the ingot or piece of metal intended to be assayed.

A'SSE. A loathing of food, from a conflux of humours.—*Hippocrates.*

ASSIMULA'TION. (*Assimilatio,* from *ad,* and *similis,* to make like to.) The conversion of the food into nutriment.

ASSISTE'NTES. (From *ad,* and *sisto,* to stand near.) A name of the prostrate glands, so called because they lie near the bladder.

ASSO'DES. (From ασαομαι, to nauseate, or from *assare,* to burn.) *Asodes.* A continual fever, attended with a loathing of food.

A'SSOS. A name given formerly to alumen.

A'STACUS. (*Astacus, i.* m.; from α, neg. and ϛαζω, to distil; so called from the hardness and dryness of its shell.) The name of a genus of shell-fish.

ASTACUS FLUVIATILIS. The officinal crevis, or cray-fish. See *Cancer astacus.*

ASTACUS MARINUS. The lobster. See *Cancer gammarus.*

A'STAPSIS. (From ϛαφις, uva passa.) A raisin.

ASTA'RZOF. The name of an ointment of litharge, house-leek, &c.—*Paracelsus.*

ASTCHACHILOS. A malignant ulcer, by some called araneus.

ASTERA'NTIUM. (From αϛηρ, a star.) The pellitory; so called from its star-like form. See *Anthemis pyrethrum.*

ASTERICUM. (From the star-like appearance of the flowers.) The pellitory. See *Anthemis pyrethrum.*

ASTHE'NIA. (From α, priv. and σθενος, strength.) Extreme debility. The asthenic diseases form one great branch of the Brunonian arrangement.

ASTHENOLOGY. (*Asthenologia, æ.* f.; from α, priv. and σθενος, strength, and λογος, a treatise.) The doctrine of diseases arising from debility. The disciples of the Brunonian school, as they denominate themselves, maintain peculiar opinions on this subject.

A'STHMA. (*Asthma, matis.* neut.; from ασθμαζω, to breathe with difficulty.) Difficult respiration, returning at intervals, with a sense of stricture across the breast, and in the lungs; a wheezing, hard cough, at first, but more free towards the close of each paroxysm, with a discharge of mucus, followed by a remission. It is ranked by Cullen in the class *Neurosis,* and order *Spasmi.* There are, according to him, three species of asthma:—

1. *Asthma spontaneum,* when without any manifest cause.
2. *Asthma plethoricum,* when it arises from plethora.
3. *Asthma exanthematicum,* originating from the repulsion of some acrid humour.

Asthma rarely appears before the age of puberty, and seems to attack men more frequently than women, particularly those of a full habit, in whom it never fails, by frequent repetition, to occasion some degree of emaciation. In some instances, it arises from an hereditary predisposition, and in many others, it seems to depend upon a particular constitution of the lungs. Dyspepsia always prevails, and appears to be a very prominent feature in the predisposition. Its attacks are most frequent during the heats of summer, in the dog-days, and in general commence about midnight. On the evening preceding an attack of asthma, the spirits are often much affected, and the person experiences a sense of fulness about the stomach, with lassitude, drowsiness, and a pain in the head. On the approach of the succeeding evening, he perceives a sense of tightness and stricture across the breast, and a sense of straitness in the lungs, impeding respiration. The difficulty of breathing continuing to increase for some length of time, both inspiration and expiration are performed slowly, and with a wheezing noise; the speech becomes difficult and uneasy, a propensity to coughing succeeds, and the patient can no longer remain in a horizontal position, being as it were threatened with immediate suffocation. These symptoms usually continue till towards the approach of morning, and then a remission commonly takes place; the breathing becomes less laborious and more full, and the person speaks and coughs with greater ease. If the cough is attended with an expectoration of mucus, he experiences much relief, and soon falls asleep. When he awakes in the morning, he still feels some degree of tightness across his breast, although his breathing is probably more free and easy, and he cannot bear the least motion, without rendering this more difficult and uneasy; neither can he continue in bed, unless his head and shoulders are raised to a considerable height. Towards evening, he again becomes drowsy, is much troubled with flatulency in the stomach, and perceives a return of the difficulty of breathing, which continues to increase gradually, till it becomes as violent as on the night before. After some nights passed in this way, the fits at length moderate, and suffer more considerable remissions, particularly when they are attended by a copious expectoration in the mornings, and this continues from time to time throughout the day; and the disease going off at last, the patient enjoys his usual rest by night, without further disturbance. The pulse is not necessarily affected in this disease, though often quickened by the difficulty of breathing; and sometimes slight pyrexia attends. In plethoric habits, the countenance is flushed and turgid during the fit; but in others rather pale and shrunk: in the former, too, some difficulty of breathing and wheezing usually remain in the interval; in others the recovery is more complete. On this is founded the common distinction of asthma into the humid, pituitous, or catarrhal, and the dry, spasmodic or nervous forms. The exciting causes are various:—accumulation of blood, or viscid mucus in the lungs, noxious vapours, a cold and foggy atmosphere, or a close hot air, the repulsion of eruptions, or other metastatic diseases, flatulence, accumulated fæces, violent passions, organic diseases in the thoracic viscera, &c. Sometimes the fits return at pretty regular periods; and it is generally difficult to obviate future attacks, when it has once occurred: but it often continues to recur for many years, and seldom proves fatal, except as inducing hydrothorax, phthisis, &c. The treatment must vary according to the form of the disease. In young persons of a plethoric habit, with great dyspnœa, a flushed countenance, accelerated pulse, &c. the abstraction of blood will be found to afford marked relief; but under opposite circumstances, it might be highly injurious, and we should always avoid repeating it unnecessarily. In ambiguous cases, cupping may be preferred, or leeches to the chest, with blisters. Mild cathartics should also be employed; or where costiveness appears to induce the fits, those of a more active nature. Nauseating emetics are of considerable service, especially where the patient is distressed with viscid mucus, not only by promoting perspiration and expectoration, but also by their antispasmodic power, the return of a paroxysm may often be prevented by their timely use. Squill combined with ipecacuanha is one of the best forms. Where the disease is of the purely spasmodic character, opium will be found the most powerful palliative remedy, especially if combined with æther, though it unfortunately loses some of its power by repetition; the fœtid gum resins are also useful, particularly where the bowels are torpid; and other antispasmodics may be occasionally employed. The practice of smoking, or chewing tobacco, has sometimes appeared extremely beneficial; and a cup of strong coffee has often afforded speedy relief. Means should also be employed for strengthening the system; and where there appears a tendency to serous effusion, digitalis may be very useful. But by far the most important part of the treatment consists in obviating or removing the several exciting causes, whether operating on the lungs immediately, or through the medium of the primæ viæ, &c. Individual experience can alone ascertain what state of the atmosphere as to temperature, dryness, purity, &c. shall be most beneficial to asthmatics, though a good deal depends on habit in this respect: but a due regulation of this, as well as of the diet, and other parts of regimen, will usually afford more permanent relief than any medicines we can employ.

A'STITES. (From *ad*, and *sto*, to stand near.) A name given by the ancients to the prostate glands, because they are situated near the bladder.

ASTRA'GALUS. (*Astragalus*, *i.* m.; Αςραγαλος, a cockle, or die; because it is shaped like the die used in ancient games.) 1. The ancle-bone; a bone of the *tarsus*, upon which the tibia moves. Also called the sling bone, or first bone of the foot. *Ballistæ os; aristrios; talus; quatrio; tetroros; cavicula; cavilla; diabebos; peza.* It is placed posteriorly and superiorly in the tarsus, and is formed of two parts, one large, which is called its body, the other small, like a process. The part where these two unite is termed the neck.

2. The name of a genus of plants in the Linnæan system. Class, *Diadelphia*; Order, *Decandria.*

Astragalus excapus. Stemless milk-vetch. The root of this plant, *Astragalus acaulis excapus;—leguminibus lunatis; foliis villosis* of Linnæus, is said to cure confirmed syphilis, especially when in the form of nodes and nocturnal pains.

Astragalus tragacantha. The former systematic name for the plant which affords the gum tragacanth. See *Astragalus verus.*

Astragalus verus. Goat's thorn. Milk-vetch. *Spina hirci; Astragalus tragacantha; Astragalus aculeatus.* We are indebted to a French traveller, of the name of Olivier, for the discovery that the gum tragacanth of commerce, is the produce of a species of astragalus not before known. He describes it under the name of *astragalus verus*, being different both from *A. tragacantha* of Linnæus, and from the *A. gummifera* of Labillardiere. It grows in the North of Persia. Gum tragacanth, or gum dragant, or dragon, (which is forced from this plant by the intensity of the solar rays, is concreted into irregular lumps or vermicular pieces, bent into a variety of shapes, and larger or smaller proportions, according to the size of the wound from which it issues,) is brought chiefly from Turkey, in irregular lumps, or long vermicular pieces bent into a variety of shapes: the best sort is white, semitransparent, dry, yet somewhat soft to the touch.

Gum-tragacanth differs from all the other known gums, in giving a thick consistence to a much larger quantity of water; and in being much more difficultly soluble, or rather dissolving only imperfectly. Put into water, it slowly imbibes a great quantity of the liquid, swells into a large volume, and forms a soft but not fluid mucilage; if more water be added, a fluid solution may be obtained by agitation; but the liquor looks turbid and wheyish, and on standing, the mucilage subsides, the limpid water on the surface retaining little of the gum. Nor does the admixture of the preceding more soluble gums promote its union with the water, or render its dissolution more durable: when gum-tragacanth and gum-arabic are dissolved together in water, the tragacanth separates from the mixture more speedily than when dissolved by itself.

Tragacanth is usually preferred to the other gums for making up troches, and other like purposes, and is supposed likewise to be the most effectual as a medicine; but on account of its imperfect solubility, is unfit for liquid forms. It is commonly given in powder with the addition of other materials of similar intention; thus, to one part of gum-tragacanth are added one of gum-arabic, one of starch, and six of sugar.

According to Bucholtz, gum-tragacanth is composed of 57 parts of a matter similar to gum-arabic, and 43 parts of a peculiar substance, capable of swelling in cold water without dissolving, and assuming the appearance of a thick jelly. It is soluble in boiling water, and then forms a mucilaginous solution.

The demulcent qualities of this gum are to be considered as similar to those of gum-arabic. It is seldom given alone, but frequently in combination with more powerful medicines, especially in the form of troches, for which it is peculiarly well adapted: it gives name to an officinal compound powder, and was an ingredient in the compound powder of cerusse.

ASTRA'NTIA. (From *αστρον*, *astrum*, a star; so called from the star-like shape of its flowers.) The name of a genus of plants in the Linnæan system, Class, *Pentandria*, Order, *Digynia*.

Astrantia major. *Astrantia vulgaris*. *Astrantia nigra*. The herb sanicle masterwort. A rustic purge in the time of Gerard.

A'strape. (From *αϛραπτω*, to corruscate.) Lightning. Galen reckons it among the remote causes of epilepsy.

ASTRI'CTUS. (From *astringo*, to bind.) When applied to the belly, it signifies costiveness; thus, *alvus astricta*.

ASTRI'NGENT. (*Astringens*; from *astringo*, to constringe.) Adstringent. That which, when applied to the body, renders the solids denser and firmer, by contracting their fibres, independently of their living, or muscular power. Astringents thus serve to diminish excessive discharges; and by causing greater compression of the nervous fibrillæ, may lessen morbid sensibility or irritability. Hence they may tend indirectly to restore the strength, when impaired by these causes. The chief articles of this class are the acids, alum, lime-water, chalk, certain preparations of copper, zinc, iron, and lead; the gallic acid, which is commonly found united with the true astringent principle, was long mistaken for it. Seguin first distinguished them, and, from the use of this principle in tanning skins, has given it the name of *tannin*. Their characteristic differences are, the gallic acid forms a black precipitate with iron; the astringent principle forms an insoluble compound with albumen.

ASTRONO'MY. (*Astronomia*; from *αϛρον*, a star, and *νομος*, a law.) The knowledge of the heavenly bodies. Hippocrates ranks this and astrology among the necessary studies of a physician.

ASTRUC, John, a learned physician, born in France, 1684. He studied and took his degrees at Montpelier, and became afterwards a professor there. In 1729, he was appointed physician to the king of Poland, but soon returned to his native country, was made consulting physician to the French king, and professor of medicine at Paris, where he attained great celebrity. He was author of numerous medical and philosophical works, but especially one "on Venereal Diseases," which deservedly became extremely popular, and was translated into various modern languages. He lived to the advanced age of 82.

A'suar. Indian myrobalans, or purging nut.

A'sugar. Verdigris.

Asu'oli. Soot.

A'tac. Nitre.

ATA'XIA. (From *α*, neg. and *τασσω*, to order.) Want of regularity in the symptoms of a disease, or of the functions of an animal body.

Ata'xir. (Arabian.) 1. A tenesmus.

2. A disease of the eyes.

Ata'xmir. (Arabian.) Removal of preternatural hairs growing under the natural ones of the eye-lids.

A'tebras. A chemical subliming vessel.

ATE'CNIA. (From *α*, neg. and *τικτω*, to bring forth.) Venereal impotency: inability to procreate children.

ATHAMANTA. *Athamanta*, *æ*. fœm.; so named from Athamas in Thessaly.) The name of a genus of plants in the Linnæan system. Class, *Pentandria*; Order, *Digynia*.

Athamanta cretensis. The systematic name for the *daucus creticus* of the pharmacopœias. *Myrrhus annua*. Candy carrot. The seeds of this plant, *Athamanta—foliolis linearibus planis, hirsutis; petalis bipartitis; seminibus oblongis hirsutis*, of Linnæus, are brought from the isle of Candy: they have an aromatic smell, and a slightly-biting taste; and are occasionally employed as carminatives, and diuretics in diseases of the primæ viæ and urinary passages.

Athamanta oreoselinum. The systematic name for the officinal *oreoselinum*. Black mountain parsley. The root and seed of this plant, *Athamanta—foliolis divaricatis* of Linnæus, as well as the whole herb, were formerly used medicinally. Though formerly in so high estimation as to obtain the epithet of *polychresta*, this plant is seldom used in the practice of the present day. An extract and tincture prepared from the root were said to be attendant, aperient, deobstruent, and lithontriptic. The oil obtained by distillation from the seed was esteemed to allay the tooth-ache; and the whole was recommended as an antiscorbutic and corroborant.

ATHAMANTICUM. See *Æthusa meum*.

ATHANA'SIA. (From *α*, priv. and *ϑανατος*, death; so called because its flowers do not wither easily.) 1. The immortal plant. A name given to tansy; because when stuffed up the nose of a dead corpse, it is said to prevent putrefaction. See *Tanacetum vulgare*.

2. It means also immortality.

3. The name of an antidote of Galen, and another of Oribasius.

4. It is the name also of a collyrium described by Aëtius, and of many other compositions.

Atha'nor. (Arabian.) A chemical digesting furnace.

A'thara. (From *αθηρ*, corn.) A panada, or pap for children, made of bruised corn.

Athena. A plaster in much repute among the ancients.

Athenato'rium. A thick glass cover formerly used for chemical purposes.

Athenio'nis catapotium. The name of a pill in Celsus's writings.

Atheni'ppon. *Athenippum*. The name of a collyrium.

ATHERO'MA. (*Atheroma atis*, n. *Αθηρωμα*, pulse, pap.) An encysted tumour that contains a soft substance of the consistence of a poultice.

Atho'nor. (Arab.) A chemical furnace.

ATHRIX. (*Αϑριξ*, *debilis*, weak.)

1. Weakness.

2. (From *α*, *priv.* and *θριξ*, a pair.) Baldness.

ATHY'MIA. (From *α*, neg. and *ϑυμος*, courage.) 1. Pusillanimity.

2. Despondency or melancholy.

Ati'ncar. (Arabian.) Borax.

A'TLAS. (*Atlas*, *antis*, m.; from *Ατλαω*, to sustain, because it sustains the head; or from the fable of Atlas, who was supposed to support the world upon his shoulders.) The name of the first vertebra. This vertebra differs very much from the others. See *Vertebræ*. It has no spinous process which would prevent the neck from being bent backwards, but in its place it has a small eminence. The great foramen of this is much larger than that of any other vertebra. Its body, which is small and thin, is nevertheless firm and hard. It is somewhat like a ring, and is distinguished into its *great arch*, which serves in the place of its body, and its *small posterior arch.* The atlas is joined superiorly to the head by ginglymus; and inferiorly, to the second cervical vertebra, by means of the inferior oblique processes and the odontoid process by trochoides.

ATMOMETER. The name of an instrument to measure the quantity of exhalation from a humid surface in a given time.

A'TMOSPHERE. (*Atmosphera, æ.* f.; from *ατμος*, vapour, and *σφαιρα*, a globe.) The elastic invisible fluid which surrounds the earth to an unknown height, and encloses it on all sides. Neither the properties nor the composition of the atmosphere, seem to have occupied much the attention of the ancients. Aristotle considered it as one of the four elements, situated between the regions of *water* and *fire*, and mingled with two *exhalations*, the *dry* and the *moist*; the first of which occasioned thunder, lightning, and wind; while the second produced rain, snow, and hail.

The opinions of the ancients were vague conjectures, until the matter was explained by the sagacity of Hales, and of those philosophers who followed his career.

Boyle proved beyond a doubt, that the atmosphere contained two distinct substances:—

1. An elastic fluid distinguished by the name of *air*.

2. Water in a state of vapour.

Besides these two bodies, it was supposed that the atmosphere contained a great variety of other substances which were continually mixing with it from the earth, and which often altered its properties, and rendered it noxious or fatal. Since the discovery of carbonic acid gas by Dr. Black, it has been ascertained that this elastic fluid always constitutes a part of the atmosphere.

The constituent parts of the atmosphere, therefore, are:—

1. Air. 2. Water. 3. Carbonic acid gas. 4. Unknown bodies.

1. For the properties, composition, and account of the first, see *Air*.

2. *Water.*—That the atmosphere contains water, has been always known. The rain and dew which so often precipitate from it, the clouds and fogs with which it is often obscured, and which deposit moisture on all bodies exposed to them, have demonstrated its existence in every age. Even when the atmosphere is perfectly transparent, water may be extracted from it in abundance by certain substances. Thus, if concentrated sulphuric acid be exposed to air, it gradually attracts so much moisture, that its weight is increased more than three times: it is converted into diluted acid, from which the water may be separated by distillation. Substances which have the property of abstracting water from the atmosphere, have received the epithet of *hygroscopic*, because they point out the presence of that water. Sulphuric acid, the fixed alkalies, muriate of lime, nitrate of lime, and, in general, all deliquescent salts, possess this property. The greater number of animal and vegetable bodies likewise possess it. Many of them take water from moist air, but give it out again to the air when dry. These bodies augment in bulk when they receive moisture, and diminish again when they part with it. Hence some of them have been employed as *hygrometers*, or measures of the quantity of moisture contained in the air around them. This they do by means of the increase or diminution of their length, occasioned by the addition or abstraction of moisture. This change of length is precisely marked by means of an index. The most ingenious and accurate hygrometers are those of Saussure and Deluc. In the first, the substance employed to mark the moisture is a human hair, which by its contractions and dilatations is made to turn round an index. In the second, instead of a hair, a very fine thin slip of whalebone is employed. The scale is divided into 100°. The beginning of the scale indicates extreme dryness, the end of it indicates extreme moisture. It is graduated by placing it first in air made as dry as possible by means of salts, and afterwards in air saturated with moisture. This gives the extremes of the scale, and the interval between them is divided into 100 equal parts.

The water, which constitutes a component part of the atmosphere, appears to be in the state of vapour, and chemically combined with air in the same manner as one gas is combined with another. As the quantity of the water contained in the atmosphere varies considerably, it is impossible to ascertain its amount with any degree of accuracy.

3. *Carbonic acid gas.*—The existence of carbonic gas as a constituent part of the atmosphere, was observed by Dr. Black immediately after he had ascertained the nature of that peculiar fluid. If we expose a pure alkali or alkaline earth to the atmosphere, it is gradually converted into a carbonate by the absorption of carbonic acid gas. This fact, which had been long known, rendered the inference that carbonic acid gas existed in the atmosphere unavoidable, as soon as the difference between a pure alkali and its carbonate had been ascertained to depend upon that acid. Not only alkalies and alkaline earths absorb carbonic acid when exposed to the air, but several of the metallic oxydes also.

Carbonic acid gas not only forms a constituent part of the atmosphere near the surface of the earth, but at the greatest heights which the industry of man has been able to penetrate. Saussure found it at the top of Mount Blanc, the highest point of the old continent; a point covered with eternal snow, and not exposed to the influence of vegetables or animals. Lime-water diluted with its own weight of distilled water, formed a pellicle on its surface after an hour and three-quarters exposure to the open air on that mountain; and slips of paper moistened with pure potash, acquired the property of effervescing with acids after being exposed an hour and a half in the same place. This was at a height no less than 15,668 feet above the level of the sea. Humboldt has more lately ascertained the existence of this gas in air, brought by Mr. Garnerin from a height not less than 4280 feet above the surface of the earth, to which height he had risen in an air-balloon. This fact is a sufficient proof that the presence of carbonic acid in air does not depend upon the vicinity of the earth.

Now, as carbonic acid gas is considerably heavier than air, it could not rise to great heights in the atmosphere unless it entered into combination with the air. We are warranted, therefore, to conclude, that carbonic acid is not merely mechanically mixed, but that it is chemically combined with the other constituent parts of the atmosphere. It is to the affinity which exists between carbonic acid and air that we are to ascribe the rapidity with which it disperses itself through the atmosphere, notwithstanding its great specific gravity. Fontana mixed 20,000 cubic inches of carbonic acid gas with the air of a close room, and yet half an hour after he could not discover the traces of carbonic acid in that air. Water impregnated with carbonic acid, when exposed to the air, very soon loses the whole of the combined gas. And when a phial full of carbonic acid gas is left uncorked, the gas, as Bergman first ascertained, very soon disappears, and the phial is found filled with common air.

The difficulty of separating this gas from air has hitherto prevented the possibility of determining with accuracy the relative quantity of it in a given bulk of air; but from the experiments which have been made, we may conclude with some degree of confidence, that it is not very different from 0.01. From the experiments of Humboldt, it appears to vary from 0.005 to 0.01. This variation will by no means appear improbable, if we consider that immense quantities of carbonic acid gas must be constantly mixing with the atmosphere, as it is formed by the respiration of animals, by combustion, and several other processes which are going on continually. The quantity, indeed, which is daily formed by these processes is so great, that at first sight it appears astonishing that it does not increase rapidly. The consequence of such an increase would be fatal, as air containing 0.1 of carbonic acid extinguishes light, and is destructive to animals. But there is reason to conclude, that this gas is decomposed by vegetables as rapidly as it forms.

4. *Bodies found in the atmosphere.*—From what has been advanced, it appears that the atmosphere consists chiefly of three distinct elastic fluids united together by chemical affinity; namely, air, vapour, and carbonic acid gas; differing in their proportions at different times and in different places; the average proportion of each is,

98.6	air
1.0	carbonic acid
0.4	water
100.0	

But besides these bodies, which may be considered as the constituent parts of the atmosphere, the existence of several other bodies has been suspected in it. It is not meant in this place to include among those bodies electric matter, or the substance of clouds and fogs, and those other bodies which are considered as the active agents in the phenomena of meteorology, but merely those foreign bodies which have been occasionally found or suspected in air. Concerning these bodies, however, very little satisfactory is known at present, as we are not in possession of instruments sufficiently delicate to ascertain their presence. We can indeed detect several of them actually mixing with air, but what becomes of them afterwards we are unable to say.

1. Hydrogen gas is said to have been found in air situated near the crater of volcanoes, and it is very possible that it may exist always in a very small proportion in the atmosphere; but this cannot be ascertained till some method of detecting the presence of hydrogen combined with a great proportion of air be discovered.

2. Carburetted hydrogen gas is often emitted by marshes in considerable quantities during hot weather. But its presence has never been detected in air; so that in all probability it is again decomposed by some unknown process.

3. Oxygen gas is emitted abundantly by plants during the day. There is some reason to conclude that this is in consequence of the property which plants have of absorbing and decomposing carbonic acid gas. Now as this carbonic acid gas is formed at the expense of the oxygen of the atmosphere, as this oxygen is again restored to the air by the decomposition of the acid, and as the nature of atmospheric air remains unaltered, it is clear that there must be an equilibrium between these two processes; that is to say, all the carbonic acid formed by combustion must be again decomposed, and all the oxygen abstracted must be again restored. The oxygen gas which is thus continually returning to the air by combining with it, makes its component parts always to continue in the same ratio.

4. The smoke and other bodies which are continually carried into the air by evaporation, &c. are probably soon deposited again, and cannot therefore be considered with propriety as forming parts of the atmosphere.

5. There is another set of bodies, which are occasionally combined with air, and which on account of the powerful action which they produce on the human body, have attracted a great deal of attention. These are known by the name of *contagions.*

That there is a difference between the atmosphere in different places, as far as respects its effects upon the human body, has been considered as an established point in all ages. Hence some places have been celebrated as healthy, and others avoided as pernicious, to the human constitution. It is well known that in pits and mines the air is often in such a state as to suffocate almost instantaneously those who attempt to breathe it. Some places are frequented by peculiar diseases. It is known that those who are much in the apartments of persons ill of certain maladies, are extremely apt to catch the infection; and in prisons and other places, where crowds of people are confined together, when diseases once commence, they are wont to make dreadful havoc. In all these cases, it has been supposed that a certain noxious matter is dissolved by the air, and that it is the action of this matter which produces the mischief.

This noxious matter is, in many cases, readily distinguished by the peculiarly disagreeable smell which it communicates to the air. No doubt this matter differs according to the diseases which it communicates, and the substance from which it has originated. Morveau lately attempted to ascertain its nature; but he soon found the chemical tests hitherto discovered altogether insufficient for that purpose. He has put it beyond a doubt, however, that this contagious matter is of a compound nature, and that it is destroyed altogether by certain agents. He exposed infected air to the action of various bodies, and he judged of the result by the effect which these bodies had in destroying the fœtid smell of the air. The following is the result of his experiments:

1. Odorous bodies, such as benzoin, aromatic plants, &c. have no effect whatever. 2. Neither have the solutions of myrrh, benzoin, &c. in alcohol, though agitated in infected air. 3. Pyroligneous acid is equally inert. 4. Gunpowder, when fired in infected air, displaces a portion of it; but what remains, still retains its fœtid odour. 5. Sulphuric acid has no effect; sulphurous acid weakens the odour, but does not destroy it. Distilled vinegar diminishes the odour, but its action is slow and incomplete. 7. Strong acetic acid acts instantly, and destroys the fœtid odour of infected air completely. 8. The fumes of nitric acid, first employed by Dr. Carmichael Smith, are equally efficacious. 9. Muriatic acid gas, first pointed out as a proper agent by Morveau himself, is equally effectual. 10. But the most powerful agent is oxymuriatic acid gas, first proposed by Mr. Cruickshanks, and now employed with the greatest success in the British navy and military hospitals.

Thus there are four substances which have the property of destroying contagious matter, and of purifying the air; but acetic acid cannot easily be obtained in sufficient quantity, and in a state of sufficient concentration to be employed with advantage. Nitric acid is attended with inconvenience, because it is almost always contaminated with nitrous gas. Muriatic acid and oxymuriatic acid are not attended with these inconveniences; the last deserves the preference, because it acts with greater energy and rapidity. All that is necessary is to mix together two parts of salt with one part of the black oxyde of manganese, to place the mixture in an open vessel in the infected chamber, and to pour upon it two parts of sulphuric acid. The fumes of oxymuriatic acid are immediately exhaled, fill the chamber, and destroy the contagion.

Ato'chia. (From α, neg. and τοκος, offspring; from τικτω, to bring forth.) 1. Inability to bring forth children. 2. Difficult labour.

ATOMIC THEORY. In the chemical combination of bodies with each other, it is observed that some unite in all proportions; others in all proportions as far as a certain point, beyond which combination no longer takes place: there are also many examples, in which bodies unite in one proportion only, and others in several proportions; and these proportions are definite, and in the intermediate ones no combination ensues. And it is remarkable, that when one body enters into combination with another, in several different proportions, the numbers indicating the greater proportions are exact simple multiples of that denoting the smallest proportion. In other words, if the smallest portion in which B combines with A, be denoted by 10, A may combine with twice 10 of B, or with three times 10, and so on; but with no intermediate quantities. Examples of this kind have of late so much increased in number, that the law of simple multiples bids fair to become universal with respect at least to chemical compounds, the proportions of which are definite. Mr. Dalton has founded what may be termed the atomic theory of the chemical constitution of bodies. Till this theory was proposed, we had no adequate explanation of the uniformity of the proportions of chemical compounds; or of the nature of the cause which renders combination in other proportions impossible. The following is a brief illustration of the theory. Though we appear, when we effect the chemical union of bodies, to operate on masses, yet it is consistent with the most rational view of the constitution of bodies, to believe, that it is only between their ultimate particles, or atoms, that combination takes place. By the term atoms, it has been already stated, we are to understand the smallest parts of which bodies are composed. An atom, therefore, must be mechanically indivisible, and of course a fraction of an atom cannot exist, and is a contradiction in terms. Whether the atoms of different bodies be of the same size, or of different sizes, we have no sufficient evidence. The probability is, that the atoms of different bodies are of unequal sizes; but it cannot be determined whether their sizes bear any regular proportion to their relative weights. We are equally ignorant of their shape; but it is probable, though not essential to the theory, that they are spherical. This, however, requires a little qualification. The atoms of all bodies, probably, consist of a solid corpuscle, forming a nucleus, and of an atmosphere of heat, by which that corpuscle is surrounded, for absolute contact is never supposed to take place between the atoms of bodies. The figure of a single atom may therefore be supposed to be spherical. But in compound atoms, consisting of a single central atom surrounded by other atoms of a different kind, it is obvious that the figure (contemplating the solid corpuscles only) cannot be spherical; yet if we include the atmosphere of heat, the figure of a compound atom may be spherical, or some shape approaching to a sphere. Taking for granted that combination takes place between the atoms of bodies only, Mr. Dalton has deduced from the relative weights in which bodies unite, the relative weights of their ultimate particles or atoms. When only one combination of any two elementary bodies exists, he assumes, unless the contrary can be proved, that its elements are united atom to atom: single combinations of this sort he calls binary. But if several compounds can be obtained from the same elements, they combine, he supposes, in proportions expressed by some simple multiple of the number of atoms. The following table exhibits a view of these combinations:

1 Atom of A+1 atom of B=1 atom of C, binary.
1 Atom of A+2 atoms of B=1 atom of D, ternary.
2 Atoms of A+1 atom of B=1 atom of E, ternary.
1 Atom of A+3 atoms of B=1 atom of F, quaternary.
3 Atoms of A+1 atom of B=1 atom of G, quaternary.

A different classification of atoms has been proposed by Berzelius, viz. into 1. Elementary atoms. 2. Compound atoms. The compound atoms he divides again into three different species; namely; 1st, Atoms formed of only two elementary substances, united or compound atoms of the first order. 2dly, Atoms composed of more than two elementary substances, and these as they are only found in organic bodies, or bodies obtained by the destruction of organic matter, he calls organic atoms. 3dly, Atoms formed by the union of two or more compound atoms; as, for example, the salts. These he calls compound atoms of the second order. If elementary atoms of different kinds were of the same size, the greatest number of atoms of it that could be combined with an atom of B would be 12; for this is the greatest number of spherical bodies that can be arranged in contact with a sphere of the same diameter. But this equality of size, though adopted by Berzelius, is not necessary to the hypothesis of Mr. Dalton, and is, indeed, supposed by him not to exist.

As an illustration of the mode in which the weight of the atoms of bodies is determined, let us suppose that any two elementary substances, A and B, form a binary compound, and that they have been proved experimentally to unite in the proportion by weight, of five to the former, to four of the latter, then since (according to the hypothesis) they unite particle to particle, those numbers will express the relative weight of their atoms. But besides combining atom to atom singly, 1 atom of A may combine with 2 of B, or with 3, 4, &c. or one atom of B may combine with 2 of A, or with 3, 4, &c. When such a series of compounds exists, the relative proportion of their elements ought necessarily on analysis to be proved to be 5 of A to 4 of B, or 5 to (4+4=) 8 or 5 to (4+4+4=) 12, &c., or contrariwise, 4 of B to 5 of A, or 4 to (5+5=) 10 or 4 to (5+5+5=) 15. Betwaen these there ought to be no intermediate compounds, and the existence of any such (as 5 of A to 6 of B, or 4 of B to 7½ of A) would, if clearly established, militate against the hypothesis. To verify these numbers, it may be proper to examine the combinations of A and B with some third substance, for example, with C. Let us suppose that A and C form a binary compound, in which analysis discovers 5 parts of A, and 3 of C. Then if C and B are also capable of forming a binary compound, the relative proportion of its elements ought to be 4 of B to 3 of C, for these numbers denote the relative weights of their atoms. Now this is precisely the method by which Mr. Dalton has deduced the relative weights of oxygen, hydrogen, and nitrogen, the two first from the known composition of water, and the two last from the proportion of the elements of ammonia. Extending the comparison to a variety of other bodies, he has obtained a scale of the relative weights of their atoms. In several instances additional evidence is acquired of the accuracy of the weight assigned to an element, by our obtaining the same number from an investigation of several of its compounds. For example,

1. In water, the hydrogen is to the oxygen as 1 to 8.

2. In olefiant gas, the hydrogen is to the carbon as 1 to 8.

3. In carbonic acid, the oxygen is to the carbon as 8 to 6.

Whether, therefore, we determine the weight of the atom of carbon from the proportion in which it combines with hydrogen, or with oxygen, we arrive at the same number 6, an agreement which, as it occurs in various other instances, can scarcely be an accidental coincidence. In similar manner, 8 is deducible, as representing the atom of oxygen, both from the combination of that base with hydrogen, and with carbon, and 1 is referred to be the relative weight of the atom of hydrogen, from the two principal compounds into which it enters. In selecting the body which should be assumed as unity, Mr. Dalton has been induced to fix on hydrogen, because it is that body which unites with others in the smallest proportion. Thus in water, we have 1 of hydrogen, by weight, to 8 of oxygen; in ammonia, 1 of hydrogen to 14 of nitrogen; in carburetted hydrogen, 1 of hydrogen to 6 of carbon; and in sulphuretted hydrogen, 1 of hydrogen to 16 of sulphur. Taking for granted that all these bodies are binary compounds, we have the following scale of numbers expressive of the relative weights of the atoms of their elements:

Hydrogen - -	1
Oxygen - - -	8
Nitrogen - -	14
Carbon - - -	6
Sulphur - - -	16

Drs. Wollaston and Thomas, and Professor Berzelius, on the other hand, have assumed oxygen as the decimal unit, (the first making it 10, the second 1, and the third 100,) chiefly with a view to facilitate the estimation of its numerous compounds with other bodies. This perhaps is to be regretted, even though the change may be in some respects eligible, because it is extremely desirable that chemical writers should employ an universal standard of comparison for the weights of the atoms of bodies. It is easy, however, to reduce the number to Mr. Dalton's by the rule of proportion. Thus, as 8, Mr. Dalton's number for oxygen, corrected by the latest experiments, is to 1, his number for hydrogen, so is 10, Dr. Wollaston's number for oxygen, 1.25 the number for hydrogen. Sir H. Davy has assumed with Mr. Dalton, the atom of hydrogen as unity; but that philosophor and Berzelius also have modified the theory, by taking for granted that water is a compound of one proportion (atom) of oxygen and two proportions (atoms) of hydrogen. This is founded on the fact that two measures of hydrogen gas and one of oxygen gas are necessary to form water; and on the supposition that equal measures of different gases contain equal numbers of atoms. And as in water the hydrogen is to the oxygen by weight as 1 to 8, two atoms or volumes of hydrogen must, on this hypothesis, weigh 1, and 1 atom of volume of hydrogen 8; or if we denote a single atom of dydrogen by 1, we must express an atom of oxygen by 16. It is objectionable, however, to this modification of the atomic theory, that it contradicts a fundamental proposition of Mr. Dalton, the consistency of which with mechanical principles he has fully shown; namely, that that compound of any two elements which is with most difficulty decomposed must be presumed, unless the contrary can be proved, to be a binary one. It is easy to determine, in the manner already explained, the relative weights of the atoms of two elementary bodies which unite only in one proportion; but when one body unites in different proportions with another, it is necessary in order to ascertain the weight of its atom, that we should know the smallest proportion in which the former combines with the latter. Thus if we have a body A, 100 parts of which by weight combine with not less than 32 of oxygen, the relative weight of its atom will be to that of oxygen as 100 to 32; or reducing these numbers to their lowest terms, as 25 to 8; and the number 25 will therefore express the relative weight of the atom of A. But if, in the progress of science, it should be found that 100 parts of A are capable of uniting with 16 parts of oxygen, then the relative weight of the atom of A must be doubled; for as 100 is to 16, so is 50 to 8. This example will serve to explain the changes that have been sometimes made in assigning the weights of the atoms of certain bodies, changes which it must be observed always consist either in a multiplication or division of the original weight by some simple number. There are, it must be acknowledged, a few cases in which one body combines with another in different proportions; and yet the greater proportions are not multiples of the less by any entire number. For example, we have two oxydes of iron, the first of which consists of 100 iron and about 30 oxygen; the second of 100 iron and about 45 oxygen. But the numbers 30 and 45 are to each other as 1 to 1½. It will, however, render these numbers 1 and 1½ consistent with the law of simple multiples; if we multiply each of them by 2, it will change them to 2 and 3; and if we suppose that there is an oxyde of iron, though it has not yet been obtained experimentally, consisting of 100 iron and 15 oxygen; for the multiplication of this last number by 2 and 3 will then give us the known oxydes of iron. In some cases where we have the apparent anomaly of 1 atom of one substance united with 1½ of another, it has been proposed by Dr. Thomson to remove the difficulty by multiplying both numbers by 2, and by assuming that in such compounds we have two atoms of the one combined with 3 atoms of the other. Such combinations, it is true, are exceptions to a law deduced by Berzelius, that in all inorganic compounds one of the constituents is in the state of a single atom; but they are in no respect inconsistent with the views of Mr. Dalton, and are indeed expressly admitted by him to be compatible with this hypothesis, as well as confirmed by experience. Thus, it will appear in the sequel, that some of the compounds of oxygen with nitrogen are constituted in this way. Several objections have been proposed to the theory of Mr. Dalton; of these it is only necessary to notice the most important. It has been contended that we have no evidence when one combination only of two elements exists, that it must be a binary one, and that we might equally well suppose it to be a compound of 2 atoms of the one body with 1 atom of the other. In answer to this objection, we may urge the probability, that when two elementary bodies A and B unite, the most energetic combination will be that in which one atom of A is combined with one atom of B; for an additional atom of B will introduce a new force, diminishing the attraction of these elements for each other, namely, the mutual repulsion of the atoms of B; and this repulsion will be greater in proportion as we increase the number of the atoms of B. 2dly, It has been said, that when more than one compound of two elements exists, we have no proof which of them is the binary compound, and which the ternary. For example, that we might suppose carbonic acid to be a compound of an atom of charcoal, and an atom of oxygen; and carbonic oxyde of an atom of oxygen, with two atoms of charcoal. To this objection, however, it is a satisfactory answer that such a constitution of carbonic acid and carbonic oxyde would be directly contradictory of a law of chemical combination; namely, that it is attended, in most cases, with an increase of specific gravity. It would be absurd, therefore, to suppose carbonic acid, which is the heavier body, to be only once compounded, and carbonic oxyde, which is the lighter, to be twice compounded. Moreover, it is universally observed, that of chemical compounds, the most simple are the most difficult to be decomposed; and this being the case with carbonic oxyde, we may naturally suppose it to be more simple than carbonic acid. 3dly, It has been remarked, that instead of supposing water to consist of an atom of oxygen united with an atom of hydrogen, and that the atom of the former is 7½ times heavier than that of the latter, we might with equal probability conclude, that in water we have 7½ times more atoms in number of oxygen than of hydrogen. But this, if admitted, would involve the absurdity that in a mixture of hydrogen and oxygen gases so contrived that the ultimate atoms of each should be equal in number, 7 atoms of oxygen would desert all the proximate atoms of hydrogen in order to unite with one at a distance, for which they must have naturally a less affinity.

ATONIC. *Atonicus.* Having a diminution of strength.

A'TONY. (*Atonia*, from *α*, neg. and *τεινω*, to extend.) Weakness, or a defect of muscular power.

ATRABI'LIS. (*Atrabilis*, from *atra* black, and *bilis*, bile.) 1. Black bile.

2. Melancholy.

Artrabiliaræ capsulæ. (From *atra*, black, and *bilis.*) Se *Renal glands.*

ATRACHE'LUS. (From *α*, priv. and *τραχηχος*, the neck.) Short-necked.

Atrage'ne. See *Clematis vitalba.*

Atrame'ntum sutorium. A name of green vitriol.

Atra'sia. (From *α*, neg. and *τιτραω*, to perforate.) *Atresia.* 1. Imperforate.

2. A disease where the natural openings, as the anus or vagina, have not their usual orifice.

Atreta'rum. (From *α*, neg. and *τραω*, to perforate.) A suppression of urine from the menses being retained in the vagina.

A'TRICES. (From *α*, priv. and *θριξ*, hair.) Small tubercles about the anus upon which hairs will not grow.—*Vaselius.*

A'trici. Small sinuses in the rectum, which do not reach so far up as to perforate into its cavity.

A'TRIPLEX. (*Atriplex. icis.* f.; said to be named from its dark colour, whence it was called *Atrum olus.*) The name of a genus of plants in the Linnæan system. Class, *Polygamia*; Order, *Monæcia.*

Atriplex fœtida. See *Chenopodium vulvaria.*

Atriplex hortens s. See *Atriplex sativa.*

Atriplex sativa. The systematic name for the *atriplex hortensis* of the pharmacopœias. Orache, the herb and seed of this plant, *Atriplex—caule erecto herbaceo, foliis triangularibus*, of Linnæus, have been exhibited medicinally as antiscorbutics, but the practice of the present day appears to have totally rejected them.

ATROPA. (*Atropa, æ.* f.; from *Ατροπος*, the goddess of destiny: so called from its fatal effects.) The name of a genus of plants in the Linnæan system. Class, *Pentandria*; Order, *Monogynia.*

Atropa belladonna. The systematic name for the *belladonna* of the pharmacopœias. *Solanum melonocerasus*; *Solanum lethale.* Deadly night-shade or dwale. *Atropa—caule herbaceo; foliis ovatis integris* of Linnæus. This plant has been long known as a strong poison of the narcotic kind, and the berries have furnished many instances of their fatal effects, particularly upon children that have been tempted to eat them. The activity of this plant depends on a principle *sui generis*, called *Atropia.* (See *Atropia.*) The leaves were first used internally, to discuss scirrhous and cancerous tumours; and from the good effects attending their use, physicians were induced to employ them internally, for the same disorders; and there are a considerable number of well-authenticated facts, which prove them a very serviceable and important remedy. The dose, at first, should be small; and gradually and cautiously increased. Five grains are considered a powerful dose, and apt to produce dimness of sight, vertigo, &c.

Atropa mandragora. The systematic name for the plant which affords the *radix mandragoræ* of the pharmacopœias. Mandrake. The boiled root is employed in the form of poultice, to discuss indolent tumours.

ATRO'PHIA. (*Atrophia, æ.* f.; from *α*, neg. and *τρεφω*, to nourish.) *Marasmus.* Atrophy; Nervous consumption. This disease is marked by a gradual wasting of the body, unaccompanied either by a difficulty of breathing, cough, or any evident fever, but usually attended with a loss of appetite and impaired digestion. It is arranged by Cullen in the class *Cachexiæ*, and order *Marcores.* There are four species:—

1. When it takes place from too copious evacuations, it is termed *atrophia inanitorum*; and *tabes nutricum*;—*sudatoria*;—*à sanguifluxu*, &c.

2. When from famine, *atrophia famelicorum.*

3. When from corrupted nutriment, *atrophia cacachymica.*

4. And when from an interruption in the digestive organs, *atrophia debilium.*

The atrophy of children is called *paidatrophia.* The causes which commonly give rise to atrophy, are a poor diet, unwholesome air, excess in venery, fluor albus, severe evacuations, continuing to give suck too long, a free use of spirituous liquors, mental uneasiness, and worms; but it frequently comes on without any evident cause. Along with the loss of appetite and impaired digestion, there is a diminution of strength, the face is pale and bloated, the natural heat of the body is somewhat diminished, and the lower extremities are œdematous. Atrophy, arise from whatever cause it may, is usually very difficult to cure, and not unfrequently terminates in dropsy.

A'TROPHY. See *Atrophia.*

ATROPIA. A poisonous vegetable principle, probably alkaline, recently extracted from the *Atropa belladonna*, or deadly nightshade, by Brandes. He boiled two pounds of dried leaves of *atropa belladonna* in a sufficient quantity of water, pressed the decoction out, and boiled the remaining leaves again in water. The decoctions were mixed, and some sulphuric acid was added, in order to throw down the albumen and similar bodies; the solution is thus rendered thinner, and passes more readily through the filter. The decoction was then supersaturated with potassa, by which he obtained a precipitate that, when washed with pure water and dried, weighed 89 grains. It consisted of small crystals, from which by solution in acids, and precipitation by alkalies, the new alkaline substance, atropia, was obtained in a state of purity.

The external appearance of atropia varies considerably, according to the different methods by which it is obtained. When precipitated from the decoction of the herb by a solution of potassa, it appears in the form of very small short crystals, constituting a sandy powder. When thrown down by ammonia from an aqueous solution of its salts, it appears in flakes like wax, if the solution is much diluted; if concentrated, it is gelatinous like precipitated alumina; when obtained by the cooling of a hot solution in alcohol, it crystallises in long, acicular, transparent, brilliant crystals, often exceeding one inch in length, which are sometimes feathery, at other times star-like in appearance, and sometimes they are single crystals. Atropia, however, is obtained in such a crystalline state only when rendered perfectly pure by repeated solution in muriatic acid, and precipitation by ammonia. When pure, it has no taste. Cold water has hardly any effect upon dried atropia, but it dissolves a small quantity when it is recently precipitated; and boiling water dissolves still more. Cold alcohol dissolves but a minute portion of atropia; but when boiling, it readily dissolves it. Ether and oil of turpentine, even when boiling, have little effect on atropia.

Sulphate of atropia crystallises in rhomboidal tables and prisms with square bases. It is soluble in four or five parts of cold water. It seems to effloresce in the air, when freed as much as possible from adhering sulphuric acid, by pressure between the folds of blotting paper. Its composition by Brandes seems to be,

Atropia,	38.93
Sulphuric acid,	36.52
Water,	24.55
	100.00

This analysis would make the prime equivalent of atropia so low as 5.3, oxygen being 1. Muriate of atropia appears in beautiful white brilliant crystals, which are either cubes or square plates similar to the muriate of *daturia*. He makes the composition of this salt to be,

Atropia,	39.19
Muriatic acid,	25.40
Water,	35.41
	100.00

This analysis was so conducted as to be entitled to little attention. Nitric, acetic, and oxalic acids dissolve atropia, and form acicular salts, all soluble in water and alcohol. Mr. Brandes was obliged to discontinue his experiments on the properties of this alkali. The violent headaches, pains in the back, and giddiness, with frequent nausea, which the vapour of atropia occasioned while he was working on it, had such a bad effect on his weak health, that he has entirely abstained from any further experiments.

He once tasted a small quantity of sulphate of atropia. The taste was not bitter, but merely saline; but there soon followed violent headach, shaking in the limbs, alternate sensations of heat and cold, oppression of the chest and difficulty in breathing, and diminished circulation of the blood. The violence of these symptoms ceased in half an hour. Even the vapour of the different salts of atropia produces giddiness. When exposed for a long time to the vapours of a solution of nitrate, phosphate, or sulphate of atropia, the pupil of the eye is dilated. This happened frequently to him, and when he tasted the salt of atropia, it occurred to such a degree, that it remained so for twelve hours, and the different degrees of light had no influence. *Schweigger's Journal*, xxviii. 1.

We may observe on the above, that it is highly improbable that atropia should have a saturating power, intermediate between potassa and soda.

ATTE'NUANT. (*Attenuans;* from *attenuo*, to make thin. An attenuent or diluent is that which possesses the power of imparting to the blood a more thin and more fluid consistence than it had, previous to its exhibition; such are, water, whey, and all aqueous fluids.

ATTO'LLENS. (*Attollens;* from *attollo*, to lift up. Lifting up: a term applied to some muscles, the office of which is to lift up the parts they are affixed to.

ATTOLLENS AUREM. A common muscle of the ear. *Attollens auriculæ* of Albinus and Douglas; *Superior auris* of Winslow; and *Attollens auriculam* of Cowper. It arises, thin, broad, and tendinous, from the tendon of the occipito-frontalis, from which it is almost inseparable, where it covers the aponeurosis of the temporal muscle: and is inserted into the upper part of the ear, opposite to the antihelix. Its use is to draw the ear upwards, and to make the parts into which it is inserted, tense.

ATTOLLENS OCCULI. One of the muscles which pulls up the eye. See *Rutus superior occuli.*

ATTO'NITUS MORBUS. (From *attono*, to surprise; so called because the person falls down suddenly.) *Attonitus stupor.* The apoplexy and epilepsy.

ATTRACTION. (*Attractio;* from *attraho*, to attract.) Affinity. The terms attraction, or affinity, and repulsion, in the language of modern philosophers, are employed merely as the expression of the general facts, that the masses or particles of matter have a tendency to approach and unite to, or to recede from one another, under certain circumstances. The term attraction is used synonymously with affinity. See *Affinity.*

All bodies have a tendency or power to attract each other more or less, and it is this power which is called attraction.

Attraction is mutual: it extends to indefinite distances. All bodies whatever, as well as their component elementary particles, are endued with it. It is not annihilated, at how great a distance soever we suppose them to be placed from each other; neither does it disappear though they be arranged ever so near each other.

The nature of this reciprocal attraction, or at least the cause which produces it, is altogether unknown to us. Whether it be inherent in all matter, or whether it be the consequence of some other agent, are questions beyond the reach of human understanding; but its existence is nevertheless certain.

"The instances of attraction which are exhibited by the phenomena around us, are exceedingly numerous, and continually present themselves to our observation. The effect of gravity, which causes the weight of bodies, is so universal, that we can scarcely form an idea how the universe could subsist without it. Other attractions, such as those of magnetism and electricity, are likewise observable; and every experiment in chemistry tends to show, that bodies are composed of various principles or substances, which adhere to each other with various degrees of force, and may be separated by known methods. It is a question among philosophers, whether all the attractions which obtain between bodies be referrible to one general cause modified by circumstances, or whether various original and distinct causes act upon the particles of bodies at one and the same time. The philosophers at the beginning of the present century, were disposed to consider the several attractions as essentially different, because the laws of their action differ from each other; but the moderns appear disposed to generalise this subject, and to consider all the attractions which exist between bodies, or at least those which are permanent, as depending upon one and the same cause, whatever it may be, which regulates at once the motions of the immense bodies that circulate through the celestial spaces, and those minute particles that are transferred from one combination to another in the operations of chemistry. The earlier philosophers observed, for example, that the attraction of gravitation acts upon bodies with a force which is inversely as the squares of the distances; and from mathematical deduction they have inferred, that the law of attraction between the particles themselves follows the same ratio; but when their observations were applied to bodies very near each other, or in contact, an adhesion took place, which is found to be much greater than could be deduced from that law applied to the centres of gravity. Hence they concluded, that the cohesive attraction is governed by a much higher ratio, and probably the cubes of the distances. The moderns, on the contrary, have remarked, that these deductions are too general, because, for the most part, drawn from the consideration of spherical bodies, which admit of no contact but such as is indefinitely small, and exert the same powers on each other, whichever side may be obverted. They remark, likewise, that the consequence depending on the sum of the attractions in bodies not spherical, and at minute distances from each other, will not follow the inverted ratio of the square of the distance taken from any point assumed as the centre of gravity, admitting the particles to be governed by that law; but that it will greatly differ, according to the sides of the solid which are presented to each other, and their respective distances; insomuch that the attractions of certain particles indefinitely near each other will be indefinitely increased, though the ratio of the powers acting upon the remoter particles may continue nearly the same.

That the parts of bodies do attract each other, is evident from that adhesion which produces solidity, and requires a certain force to overcome it. For the sake of perspicuity, the various effects of attraction have been considered as different kinds of affinity or powers. That power which physical writers call the attraction of cohesion, is generally called the *attraction of aggregation* by chemists. Aggregation is considered as the adhesion of parts of the same kind. Thus a number of pieces of brimstone, united by fusion, form an aggregate, the parts of which may be separated again by mechanical means. These parts have been called integrant parts; that is to say, the minutest parts into which a body can be divided, either really or by the imagination, so as not to change its nature, are called integrant parts. Thus, if sulphur and an alkali be combined together, and form liver of sulphur, we may conceive the mass to be divided and subdivided to an extreme degree, until at length the mass consists of merely a particle of brimstone and a particle of alkali. This then is an integrant part; and if it be divided further, the effect which chemists call decomposition will take place; and the particles, consisting no longer of liver of sulphur, but of sulphur alone, and alkali alone, will be what chemists call component parts or principles.

The union of bodies in a gross way is called *mixture*. Thus sand and an alkali may be mixed together. But when the very minute parts of a body unite with those of another so intimately as to form a body which has properties different from those of either of them, the union is called *combination* or *composition*. Thus, if sand and an alkali be exposed to a strong heat, the minute parts of the mixture combine and form glass.

If two solid bodies, disposed to combine together, be brought into contact with each other, the particles which touch will combine, and form a compound; and if the temperature at which this new compound assumes the fluid form be higher than the temperature of the experiment, the process will go no farther, because this new compound, being interposed between the two bodies, will prevent their further access to each other; but if, on the contrary, the freezing point of the compound be lower than this temperature, liquefaction will ensue; and the fluid particles being at liberty to arrange themselves according to the law of their attractions, the process will go on, and the whole mass will gradually be converted into a new compound, in the fluid state. An instance of this may be exhibited by mixing common salt and perfectly dry pounded ice together. The crystals of the salt alone will not liquefy unless very much heated; the crystals of the water, that is to say, the ice, will not liquefy unless heated as high as thirty-two degrees of Fahrenheit; and we have, of course, supposed the temperature of the experiment to be lower than this, because our water is in the solid state. Now it is a well-known fact, that brine, or the saturated solution of sea-salt in water, cannot be frozen unless it be cooled thirty-eight degrees lower than the freezing point of pure water. It follows then, that if the temperature of the experiment be higher than this, the first combinations of salt and ice will produce a fluid brine, and the combination will proceed until the temperature of the mass has gradually sunk as low as the freezing point of brine; after which it would cease if it were not that surrounding bodies continually tend to raise the temperature. And accordingly it is found by experiment, that if the ice and the salt be previously cooled below the temperature of freezing brine, the combination and liquefaction will not take place.

The instances in which solid bodies thus combine together not being very numerous, and the fluidity which ensues immediately after the commencement of this kind of experiment, have induced several chemists to consider fluidity in one or both of the bodies applied to each other, to be a necessary circumstance, in order that they may produce chemical action upon each other. *Corpora non agunt nisi sint fluida.*

If one of two bodies applied to each other be fluid at the temperature of the experiment, its parts will successively unite with the parts of the solid, which will by that means be suspended in the fluid, and disappear. Such a fluid is called a *solvent* or *menstruum*; and the solid body is said to be dissolved.

Some substances unite together in all proportions. In this way the acids unite with water. But there are likewise many substances which cannot be dissolved in a fluid, at a settled temperature, in any quantity beyond a certain portion. Thus, water will dissolve only about one-third of its weight of common salt; and if more salt be added, it will remain solid. A fluid which holds in solution as much of any substance as it can dissolve, is said to be *saturated* with it. But saturation with one substance is so far from preventing a fluid from dissolving another body, that it very frequently happens, that the solvent power of the compound exceeds that of the original fluid itself. Chemists likewise use the word saturation in another sense; in which it denotes, such a union of two bodies as produces a compound the most remote in its properties from the properties of the component parts themselves. In combinations where one of the principles predominate, the one is said to be supersaturated, and the other principle is said to be subsaturated.

Heat in general increases the solvent power of fluids, probably by preventing part of the dissolved substance from congealing or assuming the solid form.

It often happens, that bodies which have no tendency to unite are made to combine together by means of a third, which is then called *the medium*. Thus water and fat oils are made to unite by the medium of an alkali, in the combination called soap. Some writers, who seem desirous of multiplying terms, call this tendency to unite *the affinity of intermedium*. This case has likewise been called *disposing affinity*; but Berthollet more properly styles it *reciprocal affinity*. He likewise distinguishes affinity into *elementary*, when it is between the elementary parts of bodies; and *resulting*, when it is a compound only, and would not take place with the elements of that compound.

It very frequently happens, on the contrary, that the tendency of two bodies to unite, or remain in combination together, is weakened or destroyed by the addition of a third. Thus alcohol unites with water in such a manner as to separate most salts from it. A striking instance of this is seen in a saturated or strong solution of nitre in water. If to this there be added an equal measure of alcohol, the greater part of the nitre instantly falls down. Thus magnesia is separated from a solution of Epsom salt, by the addition of an alkali, which combines with the sulphuric acid, and separates the earth. The principle which falls down is said to be *precipitated*, and in many instances is called a *precipitate*. Some modern chemists use the term precipitation in a more extended, and rather forced sense; for they apply it to all substances thus separated. In this enunciation, therefore, they would say, that potassa precipitates soda from a solution of common salt, though no visible separation or precipitation takes place; for the soda, when disengaged from its acid, is still suspended in the water by reason of its solubility.

From a great number of facts of this nature, it is clearly ascertained, not as a probable hypothesis, but as simple matter of fact, that some bodies have a stronger tendency to unite than others; and that the union of any substance with another will exclude, or separate, a third substance, which might have been previously united with one of them; excepting only in those cases wherein the new compound has a tendency to unite with that third substance, and form a triple compound. This preference of uniting, which a given substance is found to exhibit with regard to other bodies, is by an easy metaphor called elective attraction, and is subject to a variety of cases, according to the number and the powers of the principles which are respectively presented to each other. The cases which have been most frequently observed by chemists, are those called simple elective attractions, and double elective attractions.

When a simple substance is presented or applied to another substance compounded of two principles, and unites with one of these two principles so as to separate or exclude the other, this effect is said to be produced by *simple elective attraction.*

It may be doubted whether any of our operations have been carried to this degree of simplicity. All the chemical principles we are acquainted with are simple only with respect to our power of decomposing them; and the daily discoveries of our contemporaries tend to decompose those substances, which chemists a few years ago considered as simple. Without insisting, however, upon this difficulty, we may observe, that water is concerned in all the operations which are called humid, and beyond a doubt modifies all the effects of such bodies as are suspended in it; and the variations of temperature, whether arising from an actual igneous fluid, or from a mere modification of the parts of bodies, also tend greatly to disturb the effects of elective attraction. These causes render it difficult to point out an example of simple elective attraction, which may in strictness be reckoned as such.

Double elective attraction takes place when two bodies, each consisting of two principles, are presented to each other, and mutually exchange a principle of each; by which means two new bodies, or compounds, are produced of a different nature from the original compounds.

Under the same limitations as were pointed out in speaking of simple elective attraction, we may offer instances of double elective attraction. Let oxyde of mercury be dissolved to saturation in the nitric acid, the water will then contain nitrate of mercury. Again, let potassa be dissolved to saturation in the sulphuric acid, and the result will be a solution of sulphate of potassa. If mercury were added to the latter solution, it would indeed tend to unite with the acid, but, would produce no decomposition; because the elective attraction of the acid to the alkali is the strongest. So likewise, if the nitric acid alone be added to it, its tendency to unite with the alkali, strong as it is, will not effect any change, because the alkali is already in combination with a stronger acid. But if the nitrate of mercury be added to the solution of sulphate of potassa, a change of principles will take place; the sulphuric acid will quit the alkali, and unite with the mercury, while the nitric acid combines with the alkali; and these two new salts, namely, nitrate of potassa, and sulphate of mercury, may be obtained separately by crystallization. The most remarkable circumstance in this process, is that the joint effects of the attractions of the sulphuric acid to mercury, and the nitric acid to alkali, prove to be stronger than the sum of the attractions between the sulphuric acid and the alkali, and between the nitrous acid and the mercury; for if the sum of these two last had not been weaker, the original combinations would not have been broken.

Mr. Kirvan, who first, in the year 1782 considered this subject with that attention it deserves, called the affinities which tend to preserve the original combinations, the *quiescent affinities.* He distinguished the affinities or attractions which tend to produce a change of principles, by the name of the *divellent affinities.*

Some eminent chemists are disposed to consider as effects of double affinities, those changes of principles only which would not have taken place without the assistance of a fourth principle. Thus, the mutual decomposition of sulphate of soda and nitrate of potassa, in which the alkalies are changed, and sulphate of potassa and nitrate of soda are produced, is not considered by them as an instance of double decomposition; because the nitre would have been decomposed by simple elective attraction, upon the addition of the acid only.

There are various circumstances which modify the effects of elective attraction, and have from time to time misled chemists in their deductions. The chief of these is the temperature, which, acting differently upon the several parts of compounded bodies, seldom fails to alter, and frequently reverses the effects of the affinities. Thus, if alcohol be added to a solution of nitrate of potassa, it unites with the water, and precipitates the salt at a common temperature. But if the temperature be raised, the alcohol rises, on account of its volatility, and the salt is again dissolved. Thus again, if sulphuric acid be added, in a common temperature, so a combination of phosphoric acid and lime, it will decompose the salt, and disengage the phosphoric acid; but if this same mixture of these principles be exposed to a considerable heat, the sulphuric acid will have its attraction to the lime so much diminished, that it will rise, and give place again to the phosphoric, which will combine with the lime. Again, mercury kept in a degree of heat very nearly equal to volatilising it, will absorb oxygen, and become converted into the red oxyde formerly called precipitate *per se;* but if the heat be augmented still more, the oxygen will assume the elastic state, and fly off, leaving the mercury in its original state. Numberless instances of the like nature continually present themselves to the observation of chemists, which are sufficient to establish the conclusion, that the elective attractions are not constant but at one and the same temperature.

Many philosophers are of opinion, that the variations produced by change of temperature arise from the elective attraction of the matter of heat itself. But there are no decisive experiments either in confirmation or refutation of this hypothesis.

If we except the operation of heat, which really produces a change in the elective attractions, we shall find, that most of the other difficulties attending this subject arise from the imperfect state of chemical science. If to a compound of two principles a third be added, the effect of this must necessarily be different according to its quality, and likewise according to the state of saturation of the two principles of the compounded body. If the third principle which is added be in excess, it may dissolve and suspend the compound which may be newly formed, and likewise that which might have been precipitated. The metallic solutions, decomposed by the addition of an alkali, afford no precipitate in various cases when the alkali is in excess; because this excess dissolves the precipitate, which would else have fallen down. If, on the other hand, one of the two principles of the compound body be in excess, the addition of a third substance may combine with that excess, and leave a neutral substance, exhibiting very different properties from the former. Thus, if cream of tartar, which is a salt of difficult solubility, consisting of potassa united to an excess of the acid of tartar, be dissolved in water, and chalk be added, the excess unites with part of the lime of the chalk, and forms a scarcely soluble salt; and the neutral compound, which remains after the privation of this excess of acid, is a very soluble salt, greatly differing in taste and properties from the cream of tartar. The metals and the acids likewise afford various phenomena, according to their degree of oxydation. A determinate oxydation is in general necessary for the solution of metals in acids; and the acids themselves act very differently, accordingly as they are more or less acidified. Thus, the nitrous acid gives place to acids which are weaker than the nitric acid; the sulphurous acid gives place to acids greatly inferior in attractive power or affinity to the sulphuric acid. The deception arising from effects of this nature is in a great measure produced by the want of discrimination on the part of chemical philosophers; it being evident that the properties of any compound substance depend as much upon the proportion of its ingredients, as upon their respective nature.

The presence and quantity of water is probably of more consequence than is yet supposed. Thus, bismuth is dissolved in nitrous acid, but falls when the water is much in quantity.

The power of double elective attractions, too, is disturbed by this circumstance: If muriate of lime be added to a solution of carbonate of soda, they are both decomposed, and the results are muriate of soda and carbonate of lime. But if lime and muriate of soda be mixed with just water sufficient to make them into a paste, and this be exposed to the action of carbonic acid gas, a saline efflorescence, consisting of carbonate of soda, will be formed on the surface, and the bottom of the vessel will be occupied by muriate of lime in a state of deliquescence.

Berthollet made a great number of experiments, from which he deduced the following law:—that in elective attractions the power exerted is not in the ratio of the affinity simple, but in a ratio compounded of the force of affinity and the quantity of the agent; so that quantity may compensate for weaker affinity. Thus an acid which has a weaker affinity than another for a given base, if it be employed in a certain quantity, is capable of taking part of that base from the acid which has a stronger affinity for it; so that the base will be divided between them in the compound ratio of their affinity and quantity. This division of one substance between two others, for which it has different affinities, always takes place, according to him, when three such are present under circumstances in which they can mutually act on each other. And hence it is, that the force of affinity acts most powerfully when two substances first come into contact, and continues to decrease in power as either approaches the point of saturation. For the same reason it is so difficult to separate the last portions of any substance adhering to another. Hence, if the doctrine laid down by M. Berthollet be true, to its utmost extent, it must be impossible ever to free a compound completely from any one of its constituent parts by the agency of elective attraction; so that all our best established analyses are more or less inaccurate.

The solubility or insolubility of principles, at the temperature of any experiment, has likewise tended to mislead chemists, who have deduced consequences from the first effects of their experiments. It is evident, that many separations may ensue without precipitation; because this circumstance does not take place unless the separated principle be insoluble, or nearly so. The soda cannot be precipitated from a solution of sulphate of soda, by the addition of potassa, because of its great solubility; but, on the contrary, the new compound itself, or sulphate of potassa, which is much less soluble, may fall down, if there be not enough of water present to suspend it. No certain knowledge can therefore be derived from the appearance or the want of precipitation, unless the products be carefully examined. In some instances all the products remain suspended; and in others, they all fall down, as may be instanced in the decomposition of sulphate of iron by lime. Here the acid unites with the lime, and forms sulphate of lime, which is scarcely at all soluble; and the still less soluble oxyde of iron, which was disengaged, falls down along with it.

Many instances present themselves, in which decomposition does not take place, but a sort of equilibrium of affinity is perceived. Thus, soda, added to the supertartrate of potassa, forms a triple salt by combining with its excess of acid. So likewise ammonia combines with a portion of the acid of muriate of mercury, and forms the triple compound formerly distinguished by the barbarous name of sal alembroth."

Attraction, double elective. See *Affinity, double.*

Aua'nte. (From αναινω, to dry.) A dry disease, proceeding from a fermentation in the stomach, described by Hippocrates de Morbis.

Aua'pse. The same.

Au'chen. (From αυχεω, to be proud.) The neck, which in the posture of pride, is made stiff and erect.

AUDITORY. (*Auditorius*; from *audio*, to hear.) Belonging to the organ of hearing; as auditory nerve, passage, &c.

Auditory nerve. See *Portio mollis.*

Auditory passage. See *Ear*, and *Meatus auditorius internus.*

AUGITE. Pyroxene of Haüy. A green, brown, or black mineral, found crystallised, and in grains in volcanic rocks in basaltes. It consists of silica, lime, oxyde of iron, magnesia, alumina and manganese.

Augu'stum. An epithet formerly given to several compound medicines.

Auli'scos. (From αυλος, a pipe.) A catheter, or clyster-pipe.

AU'LOS. (Αυλος, a pipe.) A catheter, canula, or clyster-pipe.

AU'RA. (*Aura*, *æ*. f.; from αω, to breathe.) Any subtile vapour or exhalation.

Aura epileptica. A sensation which is felt by epileptic patients, as if a blast of cold air ascended from the lower parts towards the heart and head.

Aura seminis. The extremely subtile and vivifying portion of the semen virile, that ascends through the Fallopian tubes, to impregnate the ovum in the ovarium.

Aura vitalis. So Helmont calls the vital heat.

AURA'NTIUM. (*Aurantium*, *i*. n.; so called, *ab aureo colore*, from its golden colour, or from *Arantium*, a town of Achaia.) The orange. See *Citrus aurantium.*

Aurantium curassavente. The Curassoa, or Curassao apple, or orange. The fruit so called seems to be the immature oranges, that by some accident have been checked in their growth. They are a grateful aromatic bitter, of a flavour very different from that of the peel of the ripe-fruit, and without any acid; what little tartness they have when fresh, is lost in drying. Infused in wine, or brandy, they afford a good bitter for the stomach. They are used to promote the discharge in issues, whence their name of *issue peas*, and to give the flavour of hops to beer.

Aurantii baccæ. See *Citrus aurantium.*

Aurantii cortex. See *Citrus auranium.*

Aurichalcum. Brass.

AURI'CULA. (*Auricula*, *æ*. f. dim. of *auris*, the ear.) 1. An auricle or little ear.

2. The external ear, upon which are several eminences and depressions; as the *helix*, *antihelix*, *tragus*, *antiragus*, *conchæ auriculæ*, *scapha* and *lobulus*. See *Ear.*

3. Applied to some parts which resemble a little ear, as the auricles of the heart.

4. In botany, applied to parts of plants, which resemble an ear in figure, as *Auricula judæ*, and *Auricula muris*, &c.

Auricula judæ. See *Petiza auricula.*

Auricula muris. See *Hieracium.*

Auriculæ cordis. The auricles of the heart. See *Heart.*

AURICULA'RIS. (*Auricularis*; from *auris*, the ear.) Pertaining to the ear.

Auricularis digitus. The little finger; so called because people generally put it into the ear, when the hearing is obstructed.

AURICULATUS. Auricled. A leaf is said to be so, when furnished at its base with a pair of leaflets, properly distinct, but occasionally liable to be joined to it, as in *Citrus aurantium.*

Auri'ga. (*Auriga*, a wagoner.) A bandage for the sides is so called because it is made like the traces of a wagon-horse.—*Galen.*

AURI'GO. (*Ab aureo colore*; from its yellow colour.) The jaundice. See *Icterus.*

AURIPI'GMENTUM. (From *aurum*, gold, and *pigmentum*, paint; so called from its colour and its use to painters.) Yellow orpiment. See *Arsenic.*

AU'RIS. (*Auris*, *is*. f.; from *aura*, air, as being the medium of hearing.) The ear, or organ of hearing.) See *Ear.*

AURISCA'LPIUM. (From *auris*, the ear, and *scalpo*, to scrape.) An instrument for cleansing the ear.

Auru'go. The jaundice.

AU'RUM. 1. Gold.

2. This term was applied to many substances by alchemists and chemists, which resembled gold in colour or virtues.

Aurum fulminans. The precipitate formed by putting ammonia into a solution of gold.

Aurum graphicum. An ore of gold.

Aurum horizontale. Oil of cinnamon and sugar.

Aurum leprosum. Antimony.

Aurum musivum. Mosaic gold. "A combination of tin and sulphur, which is thus made:

Melt twelve ounces of tin, and add to it three ounces of mercury; triturate this amalgam with seven ounces of sulphur, and three of muriate of ammonia. Put the powder into a matrass, bedded rather deep in sand, and keep it for several hours in a gentle heat; which is afterward to be raised, and continued for several hours longer. If the heat have been moderate, and not continued too long, the golden-coloured scaly porous mass, called *aurum musivum*, will be found at the bottom of the vessel; but if it have been too strong, the *aurum musivum* fuses to a black mass of a striated texture. This process is thus explained: as the heat increases, the tin, by stronger affinity, seizes and combines with the muriatic acid of the muriate of ammonia; while the alkali of that salt, combining with a portion of the sulphur, flies off in the form of a sulphuret. The combination of tin and muriatic acid sublimes; and is found adhering to the sides of the matrass. The mercury, which served to divide the tin, combines with part of the sulphur, and forms cinnabar, which also sublimes; and the remaining sulphur, with the remaining tin, forms the *aurum musivum* which occupies the lower part of the vessel. It must be admitted, however, that this explanation does not indicate the reasons why such an indirect and complicated process should be required to form a simple combination of tin and sulphur.

Aurum musivum has no taste, though some specimens exhibit a sulphureous smell. It is not soluble in water, acids, or alkaline solutions. But in the dry way it forms a yellow sulphuret, soluble in water. It deflagrates with nitre. Bergman mentions a native *aurum musivum* from Siberia, containing tin, sulphur, and a small proportion of copper.

This substance is used as a pigment for giving a golden colour to small statue or plaster figures. It is likewise said to be mixed with melted glass to imitate *lapis lazuli*.

AURUM POTABILE. Gold dissolved and mixed with oil of rosemary, to be drunk.

AURUS BRAZILIENSIS. An obsolete name of the *Calamus aromaticus*.

AUTHE′MERON. (From αυτος, the same, and ημερα, a day.) A medicine which gives relief, or is to be administered the same day.

AUTOCRATE′IA. The healing power of nature.—*Hippocrates.*

AUTOLITHO′TOMUS. (From αυτος, himself, λιθος, a stone, and τεμνω, to cut.) One who cuts himself for the stone.

AUTO′PSIA. (From αυτος, himself, and οπτομαι, to see.) Ocular evidence.

AUTO′PYROS. (From αυτος, itself, and πυρος, wheat.) Bread made with the meal of wheat, from which the bran has not been removed.—*Galen.*

AUXILIARY. Assisting. This term is applied to the means which co-operate in curing diseases, and to parts which assist others in performing certain functions. The pyramidales were called auxiliary muscles.

AVA′NSIS. *Avante.* Indigestion.

AVANTURINE. A variety of quartz rock containing mica spangles. It is found in Spain and Scotland.

AVELLA′NA. (From *Abella*, or *Avella*, a town in Campania where they grew.) The specific name of the hazel-nut. See *Corylus avellana.*

AVELLANA CATHARTICA. A purgative seed or nut, from Barbadoes, the produce of the *Jatropha curcas*. See *Jatropha curcas.*

AVELLANA MEXICANA. Cocoa and chocolate nut.

AVELLANA PURGATRIX. Garden spurge.

AVE′NA. (*Avena*, *æ*. f.; from *aveo* to covet; because cattle are so fond of it.) The oat. 1. The name of a genus of plants in the Linnæan system. Class, *Triandria;* Order, *Digynia.*

2. The pharmacopœial name of the oat.

AVENA SATIVA. The systematic name for the *avena* of the pharmacopœias. It is the seed which is commonly used, and called the oat. There are two kinds of oats: the black and the white. They have similar virtues, but the black are chiefly sown for horses. They are less farinaceous, and less nourishing, than rice, or wheat; yet afford a sufficient nourishment, of easy digestion to such as feed constantly on them. In Scotland, and some of the northern counties of England, oats form the chief bread of the inhabitants. They are much used in Germany; but, in Norway, oat bread is a luxury among the common people. Gruels, made with the flour, or meal, called oatmeal, digest easily, have a soft mucilaginous quality, by which they obtund acrimony, and are used for common drink and food in fevers, inflammatory disorders, coughs, hoarseness, roughness, and exulceration of the fauces; and water gruels answer all the purposes of Hippocrates's ptisan. Externally, poultices, with oatmeal, vinegar, and a very little oil, are good for sprains and bruises. Stimulant poultices, with the grounds of strong beer, mixed up with oatmeal, are made for tumours, &c. of a gangrenous tendency.

AVENACU. A Molucca tree, of a caustic quality.

AVENS. (*Avens*, *entis;* from *aves*, to desire.) 1. The specific name of a species of dipsosis in Good's Nosology: immoderate thirst.

2. The name of a plant. See *Geum.*

AVENIUS. Veinless. Without a vein. A term applied by botanists to a leaf which is without what they call a vein; as in *Clusia alba.*

AVENZOAR. A native of Seville, in Spain, who flourished about the beginning of the twelfth century; he was made physician to the king, and is said, but on imperfect evidence, to have attained the uncommon age of 135. He prepared his own medicines, and practised surgery, as well as physic. His principal work was a compendium of the practice of medicine called, "Al-Theiser," containing some diseases not elsewhere described, and numerous cases candidly related. He was called the Experimenter, from his careful investigation of the powers of medicines by actual trial.

AVERROES. An eminent philosopher and physician, born about the middle of the 12th century, at Corduba, in Spain. He studied medicine under Avenzoar, but does not appear to have been much engaged in the practice of it, his life exhibiting the most extraordinary vicissitudes of honours bestowed upon him as a magistrate, and persecutions which he underwent for religion. He appears to have first observed, that the small-pox occurs but once in the same person. His principal medical work, called the "Universal," is a compendium of physic, mostly collected from other authors. He died about the year 1206.

AVICENNA. A celebrated philosopher and physician, born in Chorasan, in the year 980. He studied at Bagdat, obtained a degree, and began to practise at 18; and he soon attained great wealth and honour in the court of the caliph. But during the latter part of his life, residing at Ispahan, after several years spent in travelling, he impaired his constitution by intemperance, and died of a dysentery in his 58th year. His chief work on medicine, called "Canon Medicinæ," though mostly borrowed from the Greek or other preceding writers, and in a very diffuse style, acquired great reputation, and was taught in the European colleges till near the middle of the 17th century.

AVICE′NNIA. (Named after the celebrated physician of that name.) The name of a genus of plants in the Linnæan system. Class, *Didynamia*; Order, *Angiospermia*.

AVICENNIA TOMENTOSA. The systematic name for the *Avicennia—foliis cordato-ovatis, subtus tomentosis*, of Linnæus, which affords the Malacca bean, or *Anacardium orientale* of the pharmacopœias. The fruit, or nut, so called, is of a shining black colour, heart-shaped, compressed, and about the size of the thumb-nail. It is now deservedly forgot in this country.

AVIGATO PEAR. See *Laurus persea*.

Awl-shaped. See *Leaf*.

AWN. See *Arista*.

AXE-STONE. A species of nephrite, and a subspecies of jade, from which it differs in not being of so light a green, and in having a somewhat slaty texture.

AXI′LLA. (*Axilla, æ.* f. *Atzil*, Heb. Scaliger deduces it from *ago*, to act; in this manner, *ago, axo, axa, axula, axilla.*) 1. In anatomy, the cavity under the upper part of the arm, called the arm-pit.

2. In botany, the angle formed by the branch and stem of a plant, or by the leaf with either.

AXILLARIS. (From *axilla*, the arm-pit.) Axillary. 1. Of or belonging to the *axilla*, or arm-pit.

2. In botany, leaves, &c. are said to be axillary which proceed from the angle formed by the stem and branch.

AXILLARIS. See *Axillary*.

AXILLARIS GEMMA. Axillary gem. The gem which comes out of the axilla of a plant. It is this which bears the fruit.

AXILLARY. (*Axillaris*; from *axilla*, the arm-pit.) Of or belonging to the axilla, or arm-pit.

AXILLARY ARTERIES. *Arteriæ axillares*. The axillary arteries are continuations of the subclavians, and give off, each of them, in the axilla, four mammary arteries, the subscapular, and the posterior and anterior circumflex arteries, which ramify about the joint.

AXILLARY NERVES. *Nervis axillares*. Articular nerve. A branch of the brachial plexus, and sometimes of the radial nerve. It runs outwards and backwards, around the neck of the humerus, and is lost in the muscles of the scapula.

AXILLARY VEINS. *Venæ axillares*. The axillary veins receive the blood from the veins of the arm, and evacuate it into the subclavian vein.

AXINITE. *Thumerstone*. A massive or crystallised mineral, the crystals of which resemble an axe in the form and sharpness of their edges. It is found in beds at Thum, in Saxony, and in Cornwall.

A′XIS. (From *ago*, to act.) The second vertebra. See *Dentatus*.

AXU′NGIA. (*Axungia, æ.* f.; from *axis*, an axle-tree, and *unguo*, to anoint.) Hog's lard.

AXUNGIA CURATA. Purified hog's lard.

AXUNGIA DE MUMMIA. Marrow.

A′ZAC. (Arabian.) Gum ammoniac.

AZA′GOR. Verdigris.

AZALÆA. (From *αζαλεος*, dry, from its growing in a dry soil.) The name of a genus of plants in the Linnæan system. Class, *Pentandria*, Order *Monogynia*.

AZALÆA PONTICA. The Pontic azalea.

AZAMAR. Native cinnabar. Vermilion.

AZED. A fine kind of camphire.

AZOTE. (From *α*, priv. and *ζεω*, to live; because it is unfit for respiration.) Azot. See *Nitrogen*.

Azotane. The chloride of azote.

Azote, chloride of. See *Nitrogen*.

Azote, deutoxyde of. See *Nitrogen*.

Azote, gaseous oxyde of. See *Nitrogen*.

Azote, iodide of. See *Nitrogen*.

Azote, protoxyde of. See *Nitrogen*.

A′ZOTH. An imaginary universal remedy.

A′ZUB. Alum.

Azurestone. See *Lapis lazuli*.

Azure spar, prismatic. See *Azurite*.

AZURITE. Prismatic azure spar. Lazulite of Werner. A mineral of a fine blue colour, composed of alumina, magnesia, silica, oxyde of iron, and lime. It occurs in Vorau, in Stiria, and the bishopric of Salzburg.

AZU′RIUM. Quicksilver, sulphur, and sal-ammoniac.

A′ZYGES. (From *α*, priv. and *ζυγος*, a yoke.) The os sphenoides was so called, because it has no fellow.

A′ZYGOS. (From *α*, priv. and *ζυγος*, a yoke; because it has no fellow.) Several single muscles, veins, bones, &c. are so called.

AZYGOS PROCESSUS. A process of the os sphenoides.

AZYGOS UVULÆ. A muscle of the uvula. *Palato-staphilinus* of Douglas. *Staphilinus*, or *Epistaphilinus* of Winslow. It arises at one extremity of the suture which joins the palate bones, runs down the whole length of the velum and uvula, resembling an earth-worm, and adhering to the tendons of the circumflexi. It is inserted into the tip of the uvula. Its use is to raise the uvula upwards and forwards, and to shorten it.

AZYGOS VENA. Azygos vein. *Vena sine pari*. This vein is situated in the right cavity of the thorax, upon the dorsal vertebra. It receives the blood from the vertebral, intercostal, bronchial, pericardiac, and diaphragmatic veins, and evacuates it into the vena cava superior.

B.

BABUZICA′RIUS. (*Βαβουζικαριος*; from *βαβαζω*, to speak inarticulately.) The incubus, or nightmare: so called, because, in it, the person is apt to make an inarticulate or confused noise.

BA′CCA. (*Bacca, æ.* f., a berry.) A pulpy pericarpium, or seed-vessel, enclosing several naked seeds, connected by a slender membrane, and dispersed through the pulp. It is distinguished by its figure into:

1. *Bacca rotunda*, round; as in *Ribes rubrum*, the currant, and *Grossularia*, the gooseberry.

2. *Bacca oblonga*, oblong; as in *Barbarea vulgaris*, common barberry.

3. *Bacca dicocca*; double, as in *Jasminum.*

4. *Bacca recutita*, circumcised like the prominent glans penis, without the prepuce; as in *Taxus baccata.*

From the substances it is denominated,

1. *Bacca succosa*, juicy; as in *Ribes rubrum.*

2. *Bacca corticosa*, covered with a hard bark; as in *Garcinia mangostana.*

3. *Bacca exsicca*, dry; as in *Hedera helix.*

From the number of loculaments into,

1. *Bacca unilocularis*, with one; as in the *Actæa* and *Cactus.*

2. *Bacca bilocularis*, with two; as in *Lonicera.*

3. *Bacca trilocularis*, with three; as in *Asparagus* and *Ruscus.*

4. *Bacca quadrilocularis*, with four; as *Caris quadrifolia.*

5. *Bacca quinquelocularis*, with five; as in *Melastoma.*

6. *Bacca multilocularis*, with many; as in *Nymphæa.*

From the number of the seeds into,

1. *Bacca monosperma*, with one only; as in *Daphne, Viscum,* and *Viburnum.*

2. *Bacca disperma*, with two seeds; as *Barbarea vulgaris*, and *Coffea arabica.*

3. *Bacca trisperma*, with three; as in *Sambucus*, and *Juniperis.*

4. *Bacca quadrisperma*, with four; as in *Ligustrum*, and *Ilex.*

5. *Bacca polysperma*, with many seeds; as in *Arbutus unedo, Ribes*, and *Gardenia.*

The *Bacca* is also distinguished into *simple* and *compound*, when it is composed of several berries, which are called *acini*; as in *Rubus fruticosus.*

Bacca bermudensis. The Bermuda berry. See *Sapindus saponaria.*

Bacca juniperi. The juniper berry. See *Juniperus communis.*

Bacca lauri. The laurel berry. See *Laurus nobilis.*

Bacca monspeliensis. See *Inula dysenterica.*

Bacca norlandica. The shrubby strawberry. See *Rubus arcticus.*

Bacca piscatoria. So named because fish are caught with them. See *Menispermum cocculus.*

Bacca'lia. (From *baccharum copia*, because it abounds in berries.) The bay, or laurel-tree. See *Laurus nobilis.*

BA'CCHARIS. (From *bacchus*, wine; from its fragrance resembling that liquor.) See *Inula dysenterica.*

BACCIFERUS. (From *bacca*, a berry, and *fero*, to bear.) Berry bearing.

Bacciferæ plantæ. Plants are so called which have a berry or pulpy pericarpium.

BA'CCHIA. (From *bacchus*, wine; because it generally proceeds from hard drinking and intemperance.) A name given by Linnæus to the pimpled face, which results from free living.

BACCILLUM. A little berry.

BACCIUS, Andrew, a native of Ancona, practised medicine at Rome towards the end of the 16th century, and became physician to Pope Sixtus V. He appears to have had great industry and learning from his humorous publications; of which the chief, "De Thermis," gives an extensive examination of natural waters.

Ba'cculi. 1. Is used, by some writers, for a particular kind of lozenges, shaped into little short rolls.

2. Hildanus likewise uses it for an instrument in surgery.

Bacher's Pills. Pilulæ tonicæ Bacheri. A celebrated medicine in France, employed for the cure of dropsies. Their principal ingredient is the extract of melampodium, or black hellebore.

Ba'coba. The *Banana.*

BACTISHUA, George, was a celebrated physician of Chorasan, distinguished also for his literary attainments. He was successful in curing the reigning caliph of a complaint of the stomach, which brought him into great honour; he translated several of the ancient medical authors into the Arabian language; and many of his observations are recorded by Rhazes and other succeeding physicians. His son, *Gabriel*, was in equal estimation with the famous Haroun Al Raschid, whom he cured of apoplexy by bloodletting, in opposition to the opinion of the other physicians.

Badia'ga. A kind of sponge usually sold in Russia, the powder of which is said to take away the livid marks of blows and bruises within a few hours. It is only described by Bauxbaum, and its nature is not properly understood.

Badian semen. The seed of a tree which grows in China, and smells like aniseed. The Chinese, and Dutch, in imitation of them, sometimes use the badian to give their tea an aromatic taste.

Badi'za aqua. See *Bath waters.*

Badranum semen. Indian aniseed.

Badu'cca. The Indian name for a species of capparis.

Ba'dzcher. An antidote.

Bæ'os. Βαιος. In Hippocrates it means few; but in P. Ægineta, it is an epithet for a poultice.

BAGLIVI, George, born at Ragusa in 1668, after graduating at Padua, and improving himself greatly by travelling throughout Italy, was made professor of medicine and anatomy at Rome. In 1696, he published an excellent work on the practice of physic, condemning the exclusive attachment to theory, and earnestly recommending the Hippocratic method of observation; which, he maintained, assisted by the modern improvements in anatomy and physiology, would tend greatly to the advancement of medicine. He has left also several other tracts, though he died at the early age of thirty-eight.

BAGNIGGE WELLS. A saline mineral spring, near Clerkenwell, in London, resembling the Epsom water. In most constitutions, three half-pints is considered a full dose for purging.

BA'GNIO. (From *bagno*, Italian.) A bathing or sweating-house.

Ba'hei coyolli. Ray takes it to be the *Areca*, or *Fanfel.*

Ba'hel schulli. An Indian-tree. See *Genista spinosa indica.*

Bahobal. See *Adansonia.*

Ba'iac. White lead.

Baikalite. The asbestiform species of tremolite.

BAILLIE, Matthew, born in Scotland, in the year 1760. His mother was sister of the two celebrated Hunters, Dr. William, and Mr. John; his father, a clergyman. In the early part of his education he enjoyed great advantages. After studying at Glasgow, where his father was Professor of Divinity, he was sent to one of the exhibitions of that university at Baliol College, Oxford, where he took his degrees in Physic, by which he became a Fellow of the College of Physicians in London, and was soon after elected Fellow of the Royal Society. At an early period he came to London and was an inmate with his uncle, Dr. William Hunter, at that time lecturing to a numerous class of pupils, and who had the superintendence of his education. After demonstrating in the dissecting room with the celebrated and learned Mr. Cruickshanks, he became, on the death of his uncle, joint lecturer with him, and continued to lecture until 1799.

Dr. Baillie's practice as a physician was for several years extremely small, and he often complained of the little he had to do; indeed, at one time he thought of leaving the metropolis. In the year 1787, he was elected physician to St. George's Hospital; and he now began to find his practice increase. About this period he married.

Dr. Denman, the celebrated accoucheur of the day, had two daughters; Mr. Croft, afterward Sir Richard, married one, Dr. Baillie, the other. The confidence which the two first obtained in the higher circles of society, was great and extensive; and they lost no opportunity of requiring the opinion and attendance of their relation. Dr. Baillie's pupils had now gone yearly to every part of England, and the Indies, and were not merely enforcing the principles and doctrines of their master, whose lectures they had heard delivered with such lucid order, and clearness of expression, as to convey information in the most simple and intellible manner; but were sending their patients from the most distant parts to profit by his advice and experience. Two other circumstances soon occurred, which at once placed Dr. Baillie in a practice before unheard of. His uncle's, and his own great friend, Dr. Pitcairn, who was in great practice, was, from ill health, obliged to leave England for a more temperate climate, and he previously introduced him to all his patients; and Dr. Warren, who had enjoyed the greater part of the practice of the nobility was suddenly cut off. There was no practitioner left whose opportunities had fitted him to take the lead, and thus a field was opened for aspiring genius, ability, skill, and perseverance, which Dr. Baillie soon occupied, and from which he reaped an abundant harvest for more than twenty years.

Before he discontinued his lectures in 1799, he published an octavo volume, on Morbid Anatomy, in which is compressed more accurate and more useful information than is to be found in the elaborate works of Bonetus, Morgagni, and Lieutaud. This was followed by a large work, consisting of a series of splendid engravings to illustrate Morbid Anatomy. He also gave a description of the gravid uterus, and many important contributions to the transactions and medical collections of the time.

Dr. Baillie presented his collection of specimens of Morbid Parts to the College of Physicians, with a sum of money to be expended in keeping them in order.

The professional and moral character of this great physician cannot be too highly appreciated. To his brethren, among whom he might, from his extensive and peculiar practice, have exercised a high and reserved deportment, he was humble, attentive, communicative, and kind; and he never permitted the caprice of a patient or friends to interfere with the conduct of, or injure a practitioner, when unjustly censured.

In the exercise of his practice, he displayed a discriminating and profound knowledge; happy in the conception of the cause of symptoms, he distinguished diseases from those with which they might have been confounded, and pointed out their probable progress and termination; and in delivering his opinion, he expressed himself with clearness, decision, and candour.

His moral character was adorned by the strictest virtues, and ample charities. He died in the year 1823, in the sixty-third year of his age, from a gradual decay of the powers of nature, continuing to practice until about a year before his death, leaving a wife, a son, a daughter, and a sister, Miss Joanna Baillie, who has acquired a degree of eminence surpassed by none of her sex in any age. A few of his private professional friends have directed a simple tablet and bust from the chisel of Chantry, to be placed in Westminster Abbey, to perpetuate his high and honourable professional character, and his many private virtues.

BAILLOU, GUILLAUMEDE, commonly called *Ballonius*, was born in 1538, at Paris, where he graduated, and attained considerable eminence. He was very active in the contest for precedence between the physicians and surgeons, which was at length decided in favour of the former. His writings are numerous, though not now much esteemed; but he appears to have been the first, who properly discriminated between gout and rheumatism.

BA'LA. The plaintain-tree.

BALÆ'NA. (*Βαλαινα*; from *βαλλω*, to cast, from its power in casting up water.) The name of a genus of animals. Class, *Mammalia*; Order, *Cete*.

BALÆNA MACROCEPHALA. The systematic name of a species of whale.

Balais ruby. See *Spinelle*.

BALANCE. "The beginning and end of every exact chemical process consists in weighing. With imperfect instruments this operation will be tedious and inaccurate; but with a good balance, the result will be satisfactory; and much time, which is so precious in experimental researches, will be saved.

The balance is a lever, the axis of motion of which is formed with an edge like that of a knife; and the two dishes at its extremities are hung upon edges of the same kind. These edges are first made sharp, and then rounded with a fine hone, or a piece of buff leather. The excellence of the instrument depends, in a great measure, on the regular form of this rounded part. When the lever is considered as a mere line, the two outer edges are called points of suspension, and the inner the fulcrum. The points of suspension are supposed to be at equal distances from the fulcrum, and to be pressed with equal weights when loaded.

1. If the fulcrum be placed in the centre of gravity of the beam, and the three edges lie all in the same right line, the balance will have no tendency to one position more than another, but will rest in any position it may be placed in, whether the scales be on or off, empty or loaded.

2. If the centre of gravity of the beam, when level, be immediately above the fulcrum, it will overset by the smallest action; that is, the end which is lowest will descend: and it will do this with more swiftness, the higher the centre of gravity, and the less the points of suspension are loaded.

3. But if the centre of gravity of the beam be immediately below the fulcrum, the beam will not rest in any position but when level; and, if disturbed from this position, and then left at liberty, it will vibrate, and at last come to rest on the level. Its vibrations will be quicker, and its horizontal tendency stronger, the lower the centre of gravity, and the less the weights upon the points of suspension.

4. If the fulcrum be below the line joining the points of suspension, and these be loaded, the

beam will overset, unless prevented by the weight of the beam tending to produce a horizontal position. In this last case, small weights will equilibrate; a certain exact weight will rest in any position of the beam; and all greater weights will cause the beam to overset. Many scales are often made this way, and will overset with any considerable load.

5. If the fulcrum be above the line joining the points of suspension, the beam will come to the horizontal position, unless prevented by its own weight. If the centre of gravity of the beam be nearly in the fulcrum, all the vibrations of the loaded beam will be made in times nearly equal, unless the weights be very small, when they will be slower. The vibrations of balances are quicker, and the horizontal tendency stronger, the higher the fulcrum.

6. If the arms of a balance be unequal, the weights in equipoise will be unequal in the same proportion. It is a severe check upon a workman to keep the arms equal, while he is making the other adjustments in a strong and inflexible beam.

7. The equality of the arms of a balance is of use, in scientific pursuits, chiefly in making weights by bisection. A balance with unequal arms will weigh as accurately as another of the same workmanship with equal arms, provided the standard weight itself be first counterpoised, then taken out of the scale, and the thing to be weighed be put into the scale, and adjusted against the counterpoise; or when proportional quantities only are considered, as in chemical and in other philosophical experiments, the bodies and products under examination may be weighed against the weights, taking care always to put the weights into the same scale. For then, though the bodies may not be really equal to the weights, yet their proportions among each other may be the same as if they had been accurately so.

8. But though the quality of the arms may be well dispensed with, yet it is indispensably necessary that their relative lengths, whatever they may be, should continue invariable. For this purpose, it is necessary, either that the three edges be all truly parallel, or that the points of suspension and support should be always in the same part of the edge. This last requisite is the most easily obtained.

The balances made in London are usually constructed in such a manner, that the bearing parts form notches in the other parts of the edges; so that the scales being set to vibrate, all the parts naturally fall into the same bearing. The balances made in the country have the fulcrum edge straight, and confined to one constant bearing by two side plates. But the points of suspension are referred to notches in the edges, like the London balances. The balances here mentioned, which come from the country, are enclosed in a small iron japanned box; and are to be met with at Birmingham and Sheffield warehouses, though less frequently than some years ago; because a pocket contrivance for weighing guineas and half-guineas has got possession of the market. They are, in general, well made and adjusted, turn with the twentieth of a grain when empty, and will sensibly show the tenth of a grain, with an ounce in each scale. Their price is from five shillings to half a guinea; but those which are under seven shillings have not their edges hardened, and consequently are not durable. This may be ascertained by the purchaser, by passing the point of a penknife across the small piece which goes through one of the end boxes: if it make any mark or impression, the part is soft.

9. If a beam be adjusted so as to have no tendency to any one position, and the scales be equally loaded; then, if a small weight be added in one of the scales, that balance will turn, and the points of suspension will move with an accelerated motion, similar to that of falling bodies, but as much slower, in proportion, very nearly, as the added weight is less than the whole weight borne by the fulcrum.

10. The stronger the tendency to a horizontal position in any balance, or the quicker its vibrations, the greater additional weight will be required to cause it to turn, or incline to any given angle. No balance, therefore, can turn so quick as the motion deduced. Such a balance as is there described, if it were to turn with the ten thousandth part of the weight, would move at quickest ten thousand times slower than falling bodies; that is, the dish containing the weight, instead of falling through sixteen feet in a second of time, would fall through only two hundred parts of an inch, and it would require four seconds to move through one-third part of an inch; consequently all accurate weighing must be slow. If the indices of two balances be of equal lengths, that index which is connected with the shorter balance will move proportionally quicker than the other. Long beams are the most in request, because they are thought to have less friction: this is doubtful; but the quicker angular motion, greater strength, and less weight of a short balance, are certainly advantages.

11. Very delicate balances are not only useful in nice experiments, but are likewise much more expeditious than others in common weighing. If a pair of scales with a certain load be barely sensible to one-tenth of a grain, it will require a considerable time to ascertain the weight to that degree of accuracy, because the turn must be observed several times over, and is very small. But if no greater accuracy were required, and scales were used which would turn with the hundredth of a grain, a tenth of a grain, more or less, would make so great a difference in the turn, that it would be seen immediately.

12. If a balance be found to turn with a certain addition, and is not moved by any smaller weight, a greater sensibility may be given to that balance, by producing a tremulous motion in its parts. Thus, if the edge of a blunt saw, a file, or other similar instrument, be drawn along any part of the case or support of a balance, it will produce a jarring, which will diminish the friction on the moving parts so much, that the turn will be evident with one-third or one-fourth of the addition that would else have been required. In this way, a beam, which would barely turn by the addition of one-tenth of a grain, will turn with one-thirtieth or fortieth of a grain.

13. A balance, the horizontal tendency of which depends only on its own weight, will turn with the same addition, whatever may be the load; except so far as a greater load will produce a greater friction.

14. But a balance, the horizontal tendency of which depends only on the elevation of the fulcrum, will be less sensible the greater the load; and the addition requisite to produce an equal turn will be in proportion to the load itself.

15. In order to regulate the horizontal tendency in some beams, the fulcrum is placed below the points of suspension, and a sliding weight is put upon the cock or index, by means of which the centre of gravity may be raised or depressed. This is a useful contrivance.

16. Weights are made by a subdivision of a standard weight. If the weight be continually

halved it will produce the common pile, which is the smallest number for weighing between its extremes, without placing any weight in the scale with the body under examination. Granulated lead is a very convenient substance to be used in this operation of halving, which, however, is very tedious. The readiest way to subdivide small weights, consists in weighing a certain quantity of small wire, and afterward cutting it into such parts, by measure, as are desired; or the wire may be wrapped close round two pins, and then cut asunder with a knife. By this means it will be divided into a great number of equal lengths, or small rings. The wire ought to be so thin, as that one of these rings may barely produce a sensible effect on the beam. If any quantity (as, for example, a grain) of these rings be weighed, and the number then reckoned, the grain may be subdivided in any proportion, by dividing that number, and making the weights equal to as many of the rings as the quotient of the division denotes. Then, if 750 of the rings amounted to a grain, and it were required to divide the grain decimally, downwards, 9-10 would be equal to 675 rings, 8-10 would be equal to 600 rings, 7-10 to 525 rings, &c. Small weights may be made of thin leaf brass. Jewellers' foil is a good material for weights below 1-10 of a grain, as low as to 1-100 of a grain; and all lower quantities may be either estimated by the position of the index, or shown by actually counting the rings of wire, the value of which has been determined.

17. In philosophical experiments, it will be found very convenient to admit no more than one dimension of weight. The grain is of that magnitude as to deserve the preference. With regard to the number of weights the chemists ought to be provided with, writers have differed according to their habits and views. Mathematicians have computed the least possible number, with which all weights within certain limits might be ascertained; but their determination is of little use. Because, with so small a number, it must often happen, that the scales will be heavily loaded with weights on each side, put in with a view only to determine the difference between them. It is not the least possible number of weights which it is necessary an operator should buy to effect his purpose, that we ought to inquire after, but the most convenient number for ascertaining his inquiries with accuracy and expedition. The error of adjustment is the least possible, when only one weight is in the scale; that is, a single weight of five grains is twice as likely to be true, as two weights, one of three, and the other of two grains, put into the dish to supply the place of the single five; because each of these last has its own probability of error in adjustment. But since it is as inconsistent with convenience to provide a single weight, as it would be to have a single character for every number; and as we have nine characters, which we use in rotation, to express higher values according to their position, it will be found very serviceable to make the set of weights correspond with our numerical system. This directs us to the set of weights as follows: 1000 grains, 900 g. 800 g. 700 g. 600 g. 500 g. 400 g. 300 g. 200 g. 100 g. 90 g. 80 g. 70 g. 60 g. 50 g. 40 g. 30 g. 20 g. 10 g. 9 g. 8 g. 7 g. 6 g. 5 g. 4 g. 3 g. 2 g. 1 g. 9-10 g. 8-10 g. 7-10 g. 6-10 g. 5-10 g. 4-10 g. 3-10 g. 2-10 g. 1-10 g. 9-100 g. 8-100 g. 7-100 g. 6-100 g. 5-100 g. 4-100 g. 3-100 g. 2-100 g. 1-100 g. With these the philosopher will always have the same number of weights in his scales as there are figures in the number expressing the weights in grains. Thus 742. 5 grains will be weighed by the weights 700, 40, 2, and 5-10."—*Ure's Chemical Dictionary.*

BALANI'NUM OLEUM. Oil of the ben-nut.

BALANOCA'STANUM. (From *βαλανος*, a nut, and *καϛανον*, a chesnut; so called from its tuberous root.) The earth-nut. See *Bunium bulbocastanum.*

BA'LANOS. (From *βαλλω*, to cast; because it sheds its fruit upon the ground.) *Balanus.* 1. An acorn.

2. The oak-tree. See *Quercus robur.*

3. Theophrastus uses it sometimes to express any glandiferous tree.

4. From the similitude of form, this word is used to express suppositories and pessaries, *βαλανος* signifying a nut.

5. A name of the glans penis.

Balas ruby. See *Spinelle.*

BALAU'STIUM. (From *βαλιος*, various, and *αυω*, to dry; so called from the variety of its colours, and its becoming soon dry; or from *βλαϛανω*, to germinate.) *Balaustia.* A large rose-like flower, of a red colour, the produce of the plant from which we obtain the granate. See *Punica granatum.*

BALBU'TIES. (From *βαβαζω*, to stammer; or from *balbel*, Heb. to stammer.) A defect of speech; properly, that sort of stammering where the patient sometimes hesitates, and immediately after, speaks precipitately. It is the *Psellismus balbutiens* of Cullen.

Baldmoney. See *Æthusa meum.*

Baldwin's phosphorus. Ignited nitrate of lime.

BALISMUS. (Βαλλισμος; from *βαλλιζω*, *tripudio, pedibus plando.*) The specific name of a disease in Good's genus *Synclonus* for shaking palsy. See *Chorea* and *Tremor.*

BALI'STA. (From *βαλλω*, to cast.) The astragulus, a bone of the foot, was formerly called os balistæ, because the ancients used to cast it from their slings.

BALLOO'N. (*Ballon*, or *balon*, French.) 1. A large glass receiver in the form of a hollow globe. For certain chemical operations *balloons* are made with two necks, placed opposite to each other; one to receive the neck of a retort, and the other to enter the neck of a second *balloon*: this apparatus is called *enfiladed balloons.* Their use is to increase the whole space of the receiver, because any number of these may be adjusted to each other. The only one of these vessels which is generally used, is a small oblong *balloon* with two necks, which is to be luted to the retort, and to the receiver, or great *balloon*; it serves to remove this receiver from the body of the furnace, and to hinder it from being too much heated.

2. A spherical bag filled with a gas of a small specific gravity, or with heated air, by the buoyancy of which it is raised into the atmosphere.

BALLO'TE. (From *βαλλω*, to send forth, and *ους*, *ωτος*, the ear; because it sends forth flowers like ears.) *Ballota.* The name of a genus of plants. Class, *Didynamia*; Order, *Gymnospermia.*

BALLOTE NIGRA. Stinking horehound. A nettle-like plant, used, when boiled, by the country people against scurvy and cutaneous eruptions.

BALM. See *Melissa.*

Balm of Gilead. See *Dracocephalum.*

Balm of Mecca. See *Amyris gileadensis.*

Balm, Turkey. See *Dracocephalum.*

BA'LNEUM. (*Balneum, ei.* n. *βαλανειον*, a bath.) A bath, or bathing-house. See *Bath.*

BALNEUM ANIMALE. The wrapping any part

of an animal, just killed, round the body, or a limb.

BALNEUM ARENÆ. A sand bath for chemical purposes. See *Bath*.

BALNEUM CALIDUM. A hot bath. See *Bath*.

BALNEUM FRIGIDUM. A cold bath. See *Bath*.

BALNEUM MARIÆ. *Balneum maris.* A warm-water bath. See *Bath*.

BALNEUM MEDICATUM. A bath impregnated with drugs.

BALNEUM SICCUM. *Balneum cinereum.* A dry bath, either with ashes, sand, or iron filings.

BALNEUM SULPHUREUM. A sulphurous bath.

BALNEUM TEPIDUM. A tepid bath. See *Bath*.

BALNEUM VAPORIS. A vapour bath.

BAL'SAM. (*Balsamum*; from *baal samen*, Hebrew.) The term balsam was anciently applied to any strong-scented, natural vegetable resin of about the fluidity of treacle, inflammable, not miscible with water, without addition, and supposed to be possessed of many medical virtues. All the turpentines, the Peruvian balsam, copaiba balsam, &c. are examples of natural balsams. Besides, many medicines compounded of various resins, or oils, and brought to this consistence, obtained the name of balsam. Latterly, however, chemists have restricted this term to vegetable juices, either liquid, or which spontaneously become concrete, consisting of a substance of a resinous nature, combined with benzoic acid, or which are capable of affording benzoic acid, by being heated alone, or with water. They are insoluble in water, but readily dissolve in alcohol and æther. The liquid balsams are copaiva, opobalsam, Peru, styrax, Tolu; the concrete are benzoin, dragon's blood, and storax.

Balsam apple, male. The fruit of the *elaterium*. See *Momordica elaterium*.

Balsam, artificial. Compound medicines are thus termed which are made of a balsamic consistence and fragrance. They are generally composed of expressed or ethereal oils, resins, and other solid bodies, which give them the consistence of butter. The basis, or body of them, is expressed oil of nutmeg, and frequently wax, butter, &c. They are usually tinged with cinnabar and saffron.

Balsam of Canada. See *Pinus Balsamea*.

Balsam, Canary. See *Dracocephalum*.

Balsam of Copaiba. See *Copaifera officinalis*.

Balsam, natural. A resin which has not yet assumed the concrete form, but still continues in a fluid state, is so called, as common turpentine, balsamum copaiva, peruvianum, tolutanum, &c.

Balsam, Peruvian. See *Myroxylon Peruiferum*.

Balsam of sulphur. See *Balsamum sulphuris*.

Balsam of Tolu. See *Toluifera balsamum*.

Balsam, Turkey. See *Dracocephalum*.

BALSAMA'TIO. (From *balsamum*, a balsam.) The embalming of dead bodies.

BALSA'MEA. (From *balsamum*, balsam.) The balm of Gilead fir; so called from its odour. See *Pinus balsamea*.

BALSAMELÆ'ON. (From *balsamum*, balsam, and ελαιον, oil.) Balm of Gilead, or true balsamum Judiacum.

BA'LSAMI OLEUM. Balm of Gilead.

BALSA'MIC. (*Balsamica*, sc. *medicamenta*; from βαλσάμον, balsam.) A term generally applied to substances of a smooth and oily consistence, which possess emollient, sweet, and generally aromatic qualities. Hoffman calls those medicines by this name which are hot and acrid, and also the natural balsams, stimulating gums, &c. by which the vital heat is increased. Dr. Cullen speaks of them under the joint title of *balsamica et resinosa*, considering that turpentine is the basis of all balsams.

BALSAMI'FERA. (From *balsamum*, balsam, and *fero*, to bear.) Balsam berry.

BALSAMIFERA BRAZILIENSIS. The copaiba tree. See *Copaifera officinalis*.

BALSAMIFERA INDICANA. Peruvian balsam tree. See *Myroxylon peruiferum*.

BALSAMITA FŒMINEA. See *Achillea ageratum*.

BALSAMITA LUTEA. See *Polygonum persicaria*.

BALSAMITA MAJOR. See *Tanacetum balsamita*.

BALSAMITA MAS. See *Tanacetum balsamita*.

BALSAMITA MINOR. Sweet maudlin.

BAL'SAMUM. (From *baal samen*, the Hebrew for the prince of oils.) A balsam. See *Balsam*.

BALSAMUM ÆGYPTIACUM. See *Amyris gileadensis*.

BALSAMUM ALPINUM. See *Amyris gileadensis*.

BALSAMUM AMERICANUM. See *Myroxylon peruiferum*.

BALSAMUM ANODYNUM. A preparation made from tacamahacca, distilled with turpentine and soap liniment, and tincture of opium; but there were a great number of balsams sold under this name formerly.

BALSAMUM ARCÆI. A preparation composed of gum-elemi and suet.

BALSAMUM ASIATICUM. See *Amyris gileadensis*.

BALSAMUM BRAZILIENSE. See *Pinus balsamea*.

BALSAMUM CANADENSE. See *Pinus balsamea*.

BALSAMUM CEPHALICUM. A distillation from oils, nutmegs, cloves, amber, &c.

BALSAMUM COMMENDATORIS. A composition of storax, benzoe, myrrh, aloes.

BALSAMUM COPAIBÆ. See *Copaifera officinalis*.

BALSAMUM EMBRYONUM. A preparation of aniseed, fallen into disuse.

BALSAMUM GENUINUM ANTIQUORUM. See *Amyris gileadensis*.

BALSAMUM GILEADENSE. See *Amyris gileadensis*.

BALSAMUM GUAIACINUM. Balsam of Peru and spirits of wine.

BALSAMUM GUIDONIS. The same as balsamum anodynum.

BALSAMUM HUNGARICUM. A balsam prepared from a coniferous tree on the Carpathian mountains.

BALSAMUM JUDAICUM. See *Amyris gileadensis*.

BALSAMUM LUCATELLI. (*Lucatelli*; so called from its inventor Lucatellus.) A preparation made of oil, turpentine, wax, and red saunders; now disused; formerly exhibited in coughs of long standing.

BALSAMUM MAS. The herb costmary. See *Tanacetum balsamita*.

BALSAMUM E MECCA. See *Amyris gileadensis*.

BALSAMUM MEXICANUM. See *Myroxylon peruiferum*.

BALSAMUM NOVUM. A new balsam from a red fruit in the West Indies.

Balsamum odoriferum. A preparation of oil, wax, and any essential oil.

Balsamum persicum. A balsam composed of storax, benzoe, myrrh, and aloes.

Balsamum peruvianum. See *Myroxylon peruiferum.*

Balsamum rackasira. This balsam, which is inodorous when cold, but of a smell approaching to that of Tolu balsam when heated, is brought from India in gourd shells. It is slightly bitter to the taste, and adheres to the teeth, on chewing. It is supposed to be one of the factitious balsams, and is scarcely ever prescribed in this country.

Balsamum samech. A factitious balsam, composed of tartar, and spirits of wine.

Balsamum saponaceum. A name given to the preparation very similar to the compound soap liniment.

Balsamum saturni. The remedy so named is prepared by dissolving the acetate of lead in oil of turpentine, by digesting the mixture till it acquires a red colour. This is found to be a good remedy for cleansing foul ulcers; but it is not acknowledged in our dispensatories.

Balsamum styracis benzoini. See *Styrax Benzoin.*

Balsamum succini. Oil of amber.

Balsamum sulphuris. A solution of sulphur in oil.

Balsamum sulphuris anisatum. Terebinthinated balsam of sulphur, and oil of aniseed.

Balsamum sulphuris barbadense. Sulphur boiled with Barbadoes tar.

Balsamum sulphuris crassum. Thick balsam of sulphur.

Balsamum sulphuris simplex. Sulphur boiled with oil.

Balsamum sulphuris terebinthinatum. This is made by digesting the sulphur with oil of turpentine; it is now confined to veterinary medicine.

Balsamum syriacum. See *Amyris gileadensis.*

Balsamum tolutanum. See *Toluifera balsamum.*

Balsamum traumaticum. Vulnerary balsam. A form of medicine intended to supply the place of the tincture commonly called Friar's balsam, so famous for curing old ulcers. The London College have named it Tinctura Benzoini composita.

Balsamum universale. The unguentum saturninum of old pharmacopœias. See *Ceratum plumbi compositum.*

Balsamum verum. See *Amyris gileadensis.*

Balsamum viride. Linseed oil, turpentine, and verdigris mixed together.

Balsamum vitæ hoffmanni. *Beaume de vie.* An artificial balsam, so named from its inventor, and composed of a great variety of the warmest and most grateful essential oils, such as nutmegs, cloves, lavender, &c. with balsam of Peru, dissolved in highly rectified spirit of wine; but it is now greatly abridged in the number of ingredients, and but little used.

Balzoi'num. The gum-benjamin.

BAMBA'LIO. (From βαμβαινω, to speak inarticulately.) A person who stammers or lisps.

Bambo'o. (An Indian root.) See *Arundo bambos.*

Ba'mia moschata. See *Hibiscus.*

Bamier. The name of a plant common in Egypt, the husk of which they dress with meat, and, from its agreeable flavour, make great use of it in their ragouts.

Ban a'rbor. The coffee-tree.

Bana'na. An Indian word. See *Musa sapientum.*

Bananei'ra. See *Banana.*

Ba'ncia. The wild parsnip.

BANDAGE. *Deligatio. Fascia.* An apparatus consisting of one or several pieces of linen, or flannel, and intended for covering or surrounding parts of the body for surgical purpurposes. Bandages are either simple or compound. The chief of the simple are the circular, the spiral, the uniting, the retaining, the expellent, and the creeping. The compound bandages used in surgery, are the T bandage, the suspensory one, the capistrum, the eighteen-tail bandage, and others, to be met with in surgical treatises.

Bandu'ra. A plant which grows in Ceylon, the root of which is said to be astringent.

Bangu'e. *Bange.* A species of opiate in great use throughout the East, for its intoxicating qualities. It is the leaf of a kind of wild hemp, growing in the countries of the Levant, and made into powder, pills, or conserves.

Ba'nica. The wild parsnip.

Bani'las. See *Epidendrum vanilla.*

Bani'lia. See *Epidendrum vanilla.*

Bao'bab. See *Adansonia digitata.*

Ba'ptica coccus. Kermes berries.

BAPTISTE'RIUM. (From βαπτω, to immerge.) A bath, or repository of water, to wash the body.

Bapti'strum. (From βαπτω, to dye.) A species of wild mustard, so called from its reddish colour.

Ba'rac. (From *Borak*, Arabian, splendid.) *Barach panis.* Nitre.

Ba'ras. (Arabian.) In M. A. Severinus, it is synonymous with Alphus, or Leuce.

Bara'thrum. (Arabian.) Any cavity or hollow place.

BA'RBA. (From *barbarus*, because wild nations are usually unshaven.) 1. The beard of man.

2. In botany a species of pubescence, or down, with which the surface of some plants are covered sometimes in patches; as in the leaves of the *Mesembryanthemum barbatum.*

3. Some vegetables have the specific name of *barba*, the ramifications of which are bushy, like a beard, as *Barba jovis*, &c.

Barba aronis. See *Arum maculatum.*

Barba capræ. See *Spirea ulmaria.*

Barba hirci. See *Tragopogon.*

Barba jovis. Jupiter's beard. This name is given to several plants, as the silver bush; the *Sempervivum majus;* and of a species of anthyllis.

BARBADOES. The name of an island in the West Indies, from which we obtain a mineral tar, and several medicinal plants.

Barbadoes cherry. See *Malphigia glabra.*

Barbadoes nut. See *Jatropha curcas.*

Barbadoes tar. See *Petroleum barbadense,* the use of which in medicine is limited to its external application, at times, in paralytic cases.

Barba'rea. (From St. Barbary, who is said to have found its virtues.) See *Erysimum barbarea.*

Barba'ria. *Barbaricum.* An obsolete term formerly applied to rhubarb.

Barbaro'ssæ pilula. Barbarossa's pill. An ancient composition of quicksilver, rhubarb, diagridium, musk, amber, &c. It was the first internal mercurial medicine which obtained any real credit.

Ba'rbarum. The name of a plaster in Scribonius Largus.

Barbatina. A Persian vermifuge seed.

BARBA'TUS. (From *barba*, a beard.)

Bearded; applied to a leaf which has a hairy or beard-like pubescence; as *Mesembryanthemum barbatum*, and *Spananthe paniculata.*

BA'RBEL. *Barbo.* An oblong fish, resembling the pike, the eating of the roe of which often brings on the cholera.

BARBERRY. See *Berberis.*

BARBEYRAC, Charles. A French physician of the 17th century, who graduated and settled at Montpelier, where he acquired great celebrity. He died in 1699, at the age of about 70, having published little, except a good account of the diseases of the chest and stomach in females. Mr. Locke, who became intimate with him abroad, considered him very similar in his manners and opinions to Sydenham. His practice is said to have been distinguished for simplicity and energy.

Barbo'ta. The barbut. A small river-fish. It is remarkable for the size of its liver, which is esteemed the most delicate part of it.

BARDA'NA. (From *bardus*, foolish; because silly people are apt to throw them on the garments of passengers, having the property of sticking to whatever they touch.) Burdock. See *Arctium lappa.*

BARE'GE. The small village of Barege, celebrated for its thermal waters, is situated on the French side of the Pyrenees, about half way between the Mediterranean and the Bay of Biscay. The hot springs are four in number. They have all the same component parts, but differ somewhat in their temperature, and in the quantity of sulphur, the hottest being most strongly penetrated with this active ingredient. The coolest of these waters raises Fahrenheit's thermometer to 73 deg.: the hottest to 120 deg. Barege waters are remarkable for a very smooth soapy feel; they render the skin very supple and pliable, and dissolve perfectly well soap and animal lymph; and are resorted to as a bath in resolving tumours of various kinds, rigidities, and contractions of the tendons, stiffness of the joints, left by rheumatic and gouty complaints, and are highly serviceable in cutaneous eruptions. Internally taken, this water gives considerable relief in disorders of the stomach, especially attended with acidity and heart-burn, in obstinate colics, jaundice, and in gravel, and other affections of the urinary organs.

Bari'glia. See *Barilla.*

BA'RILLA. *Barillor; bariglia.* The term given in commerce to the impure soda imported from Spain and the Levant. It is made by burning to ashes different plants that grow on the sea shore, chiefly of the genus *salsola*, and is brought to us in hard porous masses, of a speckled brown colour. Kelp, which is made in this country by burning sea weeds, and is called *British barilla*, is much more impure.

BARIUM. (From *barytes*, from which it is obtained.) The metallic basis of the earth barytes, so named by Sir Humphrey Davy, who discovered it.

"Take pure barytes, make it into a paste with water, and put this on a plate of platinum. Make a cavity in the middle of the barytes, into which a globule of mercury is to be placed. Touch the globule with the negative wire, and the platinum with the positive wire, of a voltaic battery of about 100 pairs of plates in good action. In a short time an amalgam will be formed, consisting of mercury and barium. This amalgam must be introduced into a little bent tube, made of glass free from lead, sealed at one end, which being filled with the vapour of naphtha, is then to be hermetically sealed at the other end. Heat must be applied to the recurved end of the tube, where the amalgam lies. The mercury will distil over, while the barium will remain.

This metal is of a dark gray colour, with a lustre inferior to that of cast iron. It is fusible at a red heat. Its density is superior to that of sulphuric acid; for though surrounded with globules of gas, it sinks immediately in that liquid. When exposed to air, it instantly becomes covered with a crust of barytes; and when gently heated in air, burns with a deep red light. It effervesces violently in water, converting this liquid into a solution of barytes."

BARK. A term very frequently employed to signify by way of eminence, Peruvian bark. See *Cinchona.*

Bark, Carribæan. See *Cinchona Caribæa.*

Bark, Jamaica. See *Cinchona Caribæa.*

Bark, Peruvian. See *Cinchona.*

Bark, red. See *Cinchona oblongifolia.*

Bark, yellow. See *Cinchona cordifolia.*

BARLEY. See *Hordeum.*

Barley, caustic. See *Cevadilla.*

Barley, pearl. See *Hordeum.*

BARM. See *Fermentum cerevisiæ.*

BARNET. A town near London, where there is a mineral water of a purging kind, of a similar quality to that of Epsom, and about half its strength.

BARO'METER. (From βαρος, weight, and μετρον, measure.) An instrument to determine the weight of the air; it is commonly called a weather-glass.

Barolyte. A carbonate of barytes.

Baro'nes. Small worms; called also Nepones.

Baro'ptis. A black stone, said to be an antidote to venomous bites.

BA'ROS. (Βαρος.) Gravity. 1. Hippocrates uses this word to express by it, an uneasy weight in any part.

2. It is also the Indian name for a species of camphire, which is distilled from the roots of the true cinnamon-tree.

Barras. Galipot. The resinous incrustation on the wounds made in fir-trees.

Barren Flower. See *Flos.*

BA'RRENNESS. See *Sterility.*

BA'RTHOLINE, Thomas, was born at Copenhagen in 1616. After studying in various parts of Europe, particularly Padua, and graduating at Basil, he became professor of anatomy in his native city; in which office he greatly distinguished himself, as well as in many other branches of learning. He was the first who described the lymphatics with accuracy; though some of these vessels, as well as the lacteals and thoracic duct, had been before discovered by other anatomists. Besides many learned works which he published, several others were unfortunately destroyed by fire in 1670; and he particularly regretted a dissertation on the ancient practice of midwifery, of which an outline was afterwards published by his son *Caspar.* Of those which remain, the most esteemed are, his epistolary correspondence with the most celebrated of his cotemporaries; his collection of cases where fœtuses have been discharged by preternatural outlets; and the "Medical and Philosophical Transactions of Copenhagen," enriched by the communications of many correspondents. This last work was in four volumes, published within the ten years preceding his death, which happened in 1680; and a fifth was afterwards added by his son.

Bartholinia'næ glandulæ. See *Sublingual glands.*

BARYCOI'A. (From *βαρυς*, heavy, and *ακουω*, to hear.) Deafness, or difficulty of hearing.

Baryoco'ccalon. (From *βαρυς*, heavy, and *κοκκαλος*, a nut; because it gives a deep sound. A name for the stramonium.

BARYPHO'NIA. (From *βαρυς*, dull, and *φωνη*, the voice.) A difficulty of speaking.

BARYTE. See *Heavy spar.*

BARY'TES. (From *βαρυς*, heavy; so called because it is very ponderous.) *Cauk; Calk; Terra ponderosa; Baryta.* Ponderous earth; Heavy earth. United with the sulphuric acid, it forms the mineral called *sulphate of barytes*, or *baroselenite.* When united to carbonic acid, it is called *aërated barytes*, or *carbonate of barytes.* See *Heavy spar.*

Barytes is a compound of barium and oxygen. Oxygen combines with two portions of barium, forming, 1. *Barytes.* 2. *Deutoxyde of barium.*

1. *Barytes*, or *protoxyde of barium*, "is best obtained by igniting, in a covered crucible, the pure crystallised nitrate of barytes. It is procured in the state of hydrate, by adding caustic potassa or soda to a solution of the muriate or nitrate. And barytes, slightly coloured with charcoal, may be obtained by strongly igniting the carbonate and charcoal mixed together in fine powder. Barytes obtained from the ignited nitrate is of a whitish-grey colour; more caustic than strontites, or perhaps even lime. It renders the syrup of violets green, and the infusion of turmeric red. Its specific gravity by Fourcroy is 4. When water in small quantity is poured on the dry earth, it slakes like quicklime, but perhaps with evolution of more heat. When swallowed it acts as a violent poison. It is destitute of smell.

When pure barytes is exposed, in a porcelain tube, at a heat verging on ignition, to a stream of dry oxygen gas, it absorbs the gas rapidly, and passes to the state of deutoxyde of barium. But when it is calcined in contact with atmospheric air, we obtain at first this deutoxyde and carbonate of barytes; the former of which passes very slowly into the latter, by absorption of carbonic acid from the atmosphere.

2. The *deutoxyde of barium* is of a greenish-grey colour, it is caustic, renders the syrup of violets green, and is not decomposable by heat or light. The voltaic pile reduces it. Exposed at a moderate heat to carbonic acid, it absorbs it, emitting oxygen, and becoming carbonate of barytes. The deutoxyde is probably decomposed by sulphuretted hydrogen at ordinary temperatures. Aided by heat, almost all combustible bodies, as well as many metals, decompose it. The action of hydrogen is accompanied with remarkable phenomena.

Water at 50° F. dissolves one-twentieth of its weight of barytes, and at 212° about one-half of its weight. It is colourless, acrid, and caustic. It acts powerfully on the vegetable purples and yellows. Exposed to the air, it attracts carbonic acid, and the dissolved barytes is converted into carbonate, which falls down in insoluble crusts.

Sulphur combines with barytes, when they are mixed together, and heated in a crucible. The same compound is more economically obtained by igniting a mixture of sulphate of barytes and charcoal in fine powder. This sulphuret is of a reddish yellow colour, and when dry without smell. When this substance is put into hot water, a powerful action is manifested. The water is decomposed, and two new products are formed, namely, hydrosulphuret, and hydroguretted sulphuret of barytes. The first crystallises as the liquid cools, the second remains dissolved. The *hydrosulphuret* is a compound of 9.75 of barytes with 2.125 sulphuretted hydrogen. Its crystals should be quickly separated by filtration, and dried by pressure between the folds of porous paper. They are white scales, have a silky lustre, are soluble in water, and yield a solution having a greenish tinge. Its taste is acrid, sulphureous, and when mixed with the hydroguretted sulphuret, eminently corrosive. It rapidly attracts oxygen from the atmosphere, and is converted into the sulphate of barytes. The *hydroguretted sulphuret* is a compound of 9.75 barytes with 4.125 bisulphuretted hydrogen: but contaminated with sulphite and hyposulphite in unknown proportions. The dry sulphuret consists probably of 2 sulphur + 9.75 barytes. The readiest way of obtaining barytes water is to boil the solution of the sulphuret with deutoxyde of copper, which seizes the sulphur, while the hydrogen flies off, and the barytes remains dissolved.

Phosphuret of barytes may be easily formed by exposing the constituents together to heat in a glass tube. Their reciprocal action is so intense as to cause ignition. Like phosphuret of lime, it decomposes water, and causes the disengagement of phosphuretted hydrogen gas, which spontaneously inflames with contact of air. When sulphur is made to act on the deutoxyde of barytes, sulphuric acid is formed, which unites to a portion of the earth into a sulphate.

The salts of barytes are white, and more or less transparent. All the soluble sulphates cause in the soluble salts of barytes a precipitate insoluble in nitric acid. They are all poisonous except the sulphate; and hence the proper counter-poison is dilute sulphuric acid for the carbonate, and sulphate of soda for the soluble salts of barytes."

Pure barytes has a much stronger affinity than any other body for sulphuric acid; it turns blue tincture of cabbage green. It is entirely infusible by heat alone, but melts when mixed with various earths. Its specific gravity is 4.000. It changes quickly in the air, swells, becomes soft, and falls into a white powder, with the acquisition of about one-fifth of its weight. This slaking is much more active and speedy than that of lime. It combines with phosphorus, which compound decomposes water rapidly. It unites to sulphur by the dry and humid way. It has a powerful attraction for water, which it absorbs with a hissing noise, and consolidates it strongly. It is soluble in twenty times its weight of cold, and twice its weight of boiling water. Its crystals are long four-sided prisms of a satin-like appearance. It is a deadly poison to animals.

Other Methods of obtaining Barytes.—1. Take native carbonate of barytes; reduce it to a fine powder, and dissolve it in a sufficient quantity of diluted nitric acid; evaporate this solution till a pellicle appears, and then suffer it to crystallise in a shallow bason. The salt obtained is nitrate of barytes; expose this nitrate of barytes to the action of heat in a china cup, or silver crucible, and keep it in a dull red heat for at least one hour; then suffer the vessel to cool, and transfer the greenish solid contents, which are pure barytes, into a well-stopped bottle. When dissolved in a small quantity of distilled water, and evaporated, it may be obtained in a beautiful crystalline form.

In this process the nitric acid, added to the native carbonate of barytes, unites to the barytes, and expels the carbonic acid, and forms nitrate of barytes; on exposing this nitrate to heat, it parts with its nitric acid, which becomes decomposed into its constituents, leaving the barytes behind.

2. Pure barytes may likewise be obtained from its sulphate. For this purpose, boil powdered sulphate of barytes in a solution of twice or three times its weight of carbonate of potassa, in a Florence flask, for about two hours; filter the solution, and expose what remains on the filter to the action of a violent heat.

In this case, the sulphuric acid of the barytes unites to the potassa, and the carbonic acid of the latter joins to the barytes; hence sulphate of potassa and carbonate of barytes are obtained. The former is in solution, and passes through the filter; the latter is insoluble, and remains behind. From this artificial carbonate of barytes, the carbonic acid is driven off by heat.

BARYTÆ MURIAS. *Terra ponderosa salita.* The muriate of barytes is a very acrid and poisonous preparation. In small doses it proves sudorific, diuretic, deobstruent, and alterative; in an over-dose, emetic, and violently purgative. The late Dr. Crawford found it very serviceable in all diseases connected with scrophula; and the Germans have employed it with great success in some diseases of the skin and viscera, and obstinate ulcers. The dose of the saturated solution in distilled water, is from five to fifteen drops for children, and from fifteen to twenty for adults.

BASAAL. (Indian.) The name of an Indian tree. A decoction of its leaves, with ginger, in water, is used as a gargle in disorders of the fauces. The kernels of the fruit kill worms.—*Ray's Hist.*

BASA′LTES. (In the Æthiopic tongue, this word means *iron*, which is the colour of the stone.) A heavy and hard kind of stone, found standing up in the form of regular angular columns, composed of a number of joints, one placed upon and nicely fitted to another as if formed by the hands of a skilful architect. It is found in beds and veins in granite and mica slate, the old red sandstone, limestone, and coal formations. It is distributed over the whole world; but no where is met with in greater variety than in Scotland. The German basalt is supposed to be a watery deposit; and that of France to be of volcanic origin.

The most remarkable is the columnar basaltes, which forms immense masses, composed of columns thirty, forty, or more feet in height, and of enormous thickness. Nay, those at Fairhead are two hundred and fifty feet high. These constitute some of the most astonishing scenes in nature, for the immensity and regularity of their parts. The coast of Antrim in Ireland, for the space of three miles in length, exhibits a very magnificent variety of columnar cliffs: and the Giant's Causeway consists of a point of that coast formed of similar columns, and projecting into the sea upon a descent for several hundred feet. These columns are, for the most part, hexagonal, and fit very accurately together; but most frequently not adherent to each other, though water cannot penetrate between them. And the basaltic appearances on the Hebrides Islands on the coast of Scotland, as described by Sir Joseph Banks, who visited them in 1772, are upon a scale very striking for their vastness and variety.

Basaltic hornblende. See *Hornblende.*

BASANITE. See *Flinty slate.*

BASANI′TES. (From ϐασανιζω, to find out.) A stone said, by Pliny, to contain a bloody juice, and useful in diseases of the liver: also a stone upon which, by some, the purity of gold was formerly said to be tried, and of which medical mortars were made.

BASE. See *Basis.*

Base, acidifiable. See *Acid.*

Base, acidifying. See *Acid.*

BASIA′TIO. (From *basio*, to kiss.) Venereal connexion between the sexes.

BASIA′TOR. See *Orbicularis oris.*

BASIL. See *Ocimum basilicum.*

BASILA′RIS. See *Basilary.*

BASILARIS ARTERIA. Basilary artery. An artery of the brain; so called, because it lies upon the basilary process of the occipital bone. It is formed by the junction of the two vertebral arteries within the skull, and runs forwards to the sella turcica along the pons varolii, which it supplies, as well as the adjacent parts, with blood.

BASILARIS PROCESSUS. See *Occipital bone.*

BASILARIS APOPHYSIS. See *Occipital bone.*

BASILLA′RY. (*Basilaris*; from βασιλευς, a king.) Several parts of the body, bones, arteries, veins, processes, &c. were so named by the ancients, from their situation being connected with or leading to the liver or brain, which they considered as the seat of the soul or royalty.

BASI′LICA MEDIANA. See *Basilica vena.*

BASILICA NUX. The walnut.

BASILICA VENA. The large vein that runs in the internal part of the arm, and evacuates its blood into the axillary vein. The branch which crosses, at the head of the arm, to join this vein, is called the *basilic median.* They may either of them be opened in the operation of blood-letting.

Basilicon. See *Basilicum unguentum.*

BASI′LICUM. (From βασιλικος, royal; so called from its great virtues.) See *Ocimum basilicum.*

BASILICUM UNGUENTUM. *Unguentum basilicum flavum.* An ointment popularly so called from its having the ocimum basilicum in its composition. It came afterwards to be composed of wax, resin, &c. and is now called *ceratum resinæ.*

BASILICUS. (From βασιλευς, a king. See *Basilary.*) Basilic.

BASILICUS PULVIS. The royal powder. A separation formerly composed of calomel, rhubarb, and jalap. Many compositions, were, by the ancients, so called, from their supposed pre-eminence.

BASILI′DION. An itchy ointment was formerly so called by Galen.

BA′SILIS. A name formerly given to collyriums of supposed virtues, by Galen.

BASILI′SCUS. (From βασιλευς, a king.) 1. The basilisk, or cockatrice, a poisonous serpent; so called from a white spot upon its head, which resembles a crown.

2. The philosopher's stone.

3. Corrosive sublimate.

BASIO. Some muscles so have the first part of their names, because they originate from the basilary process of the occipital bone.

BASIO-CERATO-CHONDRO-GLOSSUS. See *Hyoglossus.*

BASIO-GLOSSUM. See *Hyoglossus.*

BASIO-PHARYNGÆUS. See *Constrictor pharyngis medius.*

BA′SIS. (From βαινω, to go: the support of any thing, upon which it stands or goes.) Base. 1. This word is frequently applied anatomically to the body of any part, or to that part from which the other parts appear, as it were, to proceed, or by which they are supported.

2. In pharmacy it signifies the principal ingredient.

3. In chemistry, usually applied to alkalies, earths, and metallic oxydes, in their relations to

the acids and salts. It is sometimes also applied to the particular constituents of an acid or oxyde, on the supposition that the substance combined with the oxygen, &c. is the basis of the compound to which it owes its particular qualities. This notion seems unphilosophical, as these qualities depend as much on the state of combination as on the nature of the constituent.

Bassi colica. The name of a medicine in Scribonius Largus, compounded of aromatics and honey.

BASSORINE. This substance is extracted from the gum resins which contain it, by treating them successively with water, alcohol, and æther. Bassorine being insoluble in these liquids, remains mixed merely with the woody particles, from which it is easy to separate it, by repeated washings and decantations: because one of its characteristic properties is to swell extremely in the water and to become very buoyant. This substance swells up in cold as well as boiling water, without any of its parts dissolving. It is soluble however almost completely by the aid of heat, in water sharpened with nitric or muriatic acid. If after concentrating with a gentle heat the nitric solution, we add highly rectified alcohol, there results a white precipitate, flocculent and bulky, which, washed with much alcohol and dried, does not form, at the utmost, the tenth of the quantity of bassorine employed, and which presents all the properties of gum-arabic. *Vauquelin, Bulletin de Pharmacie*, iii. 56.

BASTARD. A term often employed in medicine, and botany, to designate a disease or plant which has the appearance of, but is not in reality what it resembles: The name of that which it similates is generally attached to it, as bastard peripneumony, bastard pellitory, &c.

Bastard pellitory. See *Achillæa ptarmica.*

Bastard pleurisy. See *Peripneumonia notha.*

Bata'tas. (So the natives of Peru call the root of a convolvulus falso.) The potatoe, which is a native of that country. *See Solanum tuberosum,* and *Convolvulus batata.*

Batatas peregrina. The purging potatoe.

BATH. Βαλανειον. *Balneum.* A bath.

1. A convenient receptacle of water, for persons to wash or plunge in, either for health or pleasure. These are distinguished into hot and cold; and are either natural or artificial. The natural hot baths are formed of the water of hot springs, of which there are many in different parts of the world; especially in those countries where there are, or have evidently been, volcanoes. The artificial hot baths consist either of water, or of some other fluid, made hot by art. The cold bath consists of water, either fresh or salt, in its natural degree of heat; or it may be made colder by art, as by a mixture of nitre, sal-ammoniac, &c. The chief hot baths in our country are those of Bath and Bristol, and those of Buxton and Matlock; which latter, however, are rather warm, or tepid, than hot. The use of baths is found to be beneficial in diseases of the head, as palsies, &c.; in cuticular diseases, as leprosies, &c.; obstructions and constipations of the bowels, the scurvy, and stone; and in many diseases of women and children. The cold bath, though popularly esteemed one of the most innocent remedies yet discovered, is not, however, to be adopted indiscriminately. On the contrary, it is liable to do considerable mischief in some cases of diseased viscera, and is not, in any case, proper to be used during the existence of costiveness. As a preventive remedy for the young, and as a general bracer for persons of a relaxed fibre, especially of the female sex, it often proves highly advantageous; and, in general, the popular idea is a correct one, that the *glow* which succeeds the use of cold or temperate baths, is a test of their utility; while, on the other hand, their producing *chilliness*, head-ache, &c. is a proof of their being pernicious.

1. *The Cold Bath.* The diseases and morbid symptoms, for which the cold bath, under one form or another, may be applied with advantage, are very numerous; and some of them deserve particular attention. One of the most important of its uses is in *ardent fever;* and, under proper management, it forms a highly valuable remedy in this dangerous disorder. It is highly important, however, to attend to the precautions which the use of this vigorous remedial process requires. "Affusion with cold water," Dr. Currie observes, "may be used whenever the heat of the body is steadily above the natural standard, when there is no sense of chilliness, and especially when there is no general nor profuse perspiration. If used during the cold stage of a fever, even though the heat be higher than natural, it brings on interruption of respiration, a fluttering, weak, and extremely quick pulse, and certainly might be carried so far as to extinguish animation entirely." The most salutary consequence which follows the proper use of this powerful remedy, is the production of free and general perspiration. It is this circumstance that appears to give so much advantage to a general affusion of cold water in fevers, in preference to any partial application. The cold bath is better known, especially in this country, as a general tonic remedy in various chronic diseases. The general circumstances of disorder for which cold bathing appears to be of service, according to Dr. Saunders, are a languor and weakness of circulation, accompanied with profuse sweating and fatigue, on very moderate exertion; tremors in the limbs, and many of those symptoms usually called nervous; where the moving powers are weak, and the mind listless and indolent; but, at the same time, where no permanent morbid obstruction, or visceral disease, is present. Such a state of body is often the consequence of a long and debilitating sickness, or of a sedentary life, without using the exercise requisite to keep up the activity of the bodily powers. In all these cases, the great object to be fulfilled, is to produce a considerable reaction, from the shock of cold water, at the expense of as little heat as possible; and when cold-bathing does harm, it is precisely where the powers of the body are too languid to bring on re-action, and the chilling effects remain unopposed. When the patient feels the shock of immersion very severely, and, from experience of its pain, has acquired an insuperable dread of this application; when he has felt little or no friendly glow to succeed the first shock, but on coming out of the bath remains cold, shivering, sick at the stomach, oppressed with head-ache, languid, drowsy, and listless, and averse to food and exercise during the whole of the day, we may be sure that the bath has been too cold, the shock too severe, and no re-action produced at all adequate to the impression on the surface of the body.

There is a kind of slow, irregular fever, or rather febricula, in which Dr. Saunders has often found the cold bath of singular service. This disorder principally affects persons naturally of a sound constitution, but who lead a sedentary life, and at the same time are employed in some occupation which strongly engages their attention, requires much exertion of thought, and excites a degree of anxiety. Such persons have constantly a pulse rather quicker than natural, hot hands, restless nights, and an impaired appetite, but without any considerable derangement in the digestive organs. This disorder will continue for a long time in an irregular way, never entirely preventing their ordinary occupation, but rendering it more than usually anxious and fatiguing, and often preparing the way for confirmed hypochondriasis. Persons in this situation are remarkably relieved by the cold bath, and, for the most part, bear it well; and its use should also, if possible, be aided by that relaxation from business, and that diversion of the mind from its ordinary train of thinking, which are obtained by attending a watering place. The Doctor also found cold bathing hurtful in chlorosis, and observes, that it is seldom admissible in those cases of disease in the stomach which are brought on by high living, and constitute what may be termed the true dyspepsia.

The topical application of cold water, or of a cold saturnine lotion, in cases of local inflammation, has become an established practice; the efficacy of which is daily experienced. Burns of every description will bear a most liberal use of cold water, or even of ice; and this may be applied to a very extensive inflamed surface, without even producing the ordinary effects of general chilling, which would be brought on from the same application to a sound and healthy skin. Another very distressing symptom, remarkably relieved by cold water, topically applied, is that intolerable itching of the vagina which women sometimes experience, entirely unconnected with any general cause, and which appears to be a kind of herpes confined to that part. Cold water has also been used topically in the various cases of strains, bruises, and similar injuries, in tendinous and ligamentous parts, with success; also in rigidity of muscles, that have been long kept at rest, in order to favour the union of bone, where there appears to have been no organic injury, but only a deficiency of nervous energy, and in mobility of parts, or at most, only slight adhesions, which would give way to regular exercise of the weakened limb. Another very striking instance of the powerful effects of topical cold, in stimulating a part to action, is shown in the use of cold, or even iced water, to the vagina of parturient women, during the dangerous hæmorrhages that take place from the uterus, on the partial separation of the placenta.

2. *The Shower Bath.* A species of cold bath. A modern invention, in which the water falls through numerous apertures on the body. A proper apparatus for this purpose is to be obtained at the shops. The use of the shower bath applies, in every case, to the same purposes as the cold bath, and is often attended with particular advantages. 1. From the sudden contact of the water, which, in the common cold bath is only momentary, but which, in the shower bath, may be prolonged, repeated, and modified, at pleasure; and, secondly, from the head and breast, which are exposed to some inconvenience and danger in the common bath, being here effectually secured, by receiving the first shock of the water.

3. *The Tepid Bath.* The range of temperature, from the lowest degree of the hot bath to the highest of the cold bath, forms what may be termed the tepid. In general, the heat of water which we should term tepid, is about 90 deg. In a medicinal point of view, it produces the greatest effect in ardent fever, where the temperature is little above that of health, but the powers of the body weak, not able to bear the vigorous application of cold immersion. In cutaneous diseases, a tepid bath is often quite sufficient to produce a salutary relaxation, and perspirability of the skin.

4. *The Hot Bath.* From 93 to 96 deg. of Fahrenheit, the hot bath has a peculiar tendency to bring on a state of repose, to alleviate any local irritation, and thereby induce sleep. It is, upon the whole, a safer remedy than the cold bath, and more peculiarly applicable to very weak and irritable constitutions, whom the shock produced by cold immersion would overpower, and who have not sufficient vigour of circulation for an adequate re-action. In cases of topical inflammation, connected with a phlogistic state of body, preceded by rigor and general fever, and where the local formation of matter is the solution of the general inflammatory symptoms, experience directs us to the use of the warm relaxing applications, rather than those which, by exciting a general re-action, would increase the local complaint. This object is particularly to be consulted when the part affected is one that is essential to life. Hence it is that in fever, where there is a great determination to the lungs, and the respiration appears to be locally affected, independently of the oppression produced by mere febrile increase of circulation, practitioners have avoided the external use of cold, in order to promote the solution of the fever; and have trusted to the general antiphlogistic treatment, along with the topically relaxing application of warm vapour, inhaled by the lungs. Warm bathing appears to be peculiarly well calculated to relieve those complaints that seem to depend on an irregular or diminished action of any part of the alimentary canal; and the state of the skin, produced by immersion in warm water, seems highly favourable to the healthy action of the stomach and bowels. Another very important use of the warm bath, is in herpetic eruptions, by relaxing the skin, and rendering it more pervious, and preparing it admirably for receiving the stimulant applications of tar ointment, mercurials, and the like, that are intended to restore it to a healthy state. The constitutions of children seem more extensively relieved by the warm bath than those of adults; and this remedy seems more generally applicable to acute fevers in them than in persons of a more advanced age. Where the warm bath produces its salutary operation, it is almost always followed by an easy and profound sleep. Dr. Saunders strongly recommends the use of the tepid bath, or even one of a higher temperature, in the true menorrhagia of females. In paralytic affections of particular parts, the powerful stimulus of heated water is generally allowed; and in these cases, the effect may be assisted by any thing which will increase the stimulating properties of the water; as, for instance, by the addition of salt. In these cases, much benefit may be expected from the use of warm sea-baths. The application of the warm bath topically, as in pediluvia, or fomentations to the feet, often produces the most powerful effects in quieting irritation in fever, and bringing on a sound and refreshing repose. The cases in which the warm bath is likely to be attended with danger, are particularly those where there exists a strong tendency to a determination of blood to the head; and apoplexy has sometimes been thus brought on. The lowest temperature will be required for cutaneous complaints, and to bring on relaxation in the skin, during febrile irritation; the warmer will be necessary in paralysis: more heat should be employed on a deep-seated part than one that is superficial.

5. *The Vapour Bath.* The vapour bath, called also *Balneum laconicum*, though not much

employed in England, forms a valuable remedy in a variety of cases. In most of the hot natural waters on the Continent, the vapour bath forms a regular part of the bathing apparatus, and is there highly valued. In no country, however, is this application carried to so great an extent as in Russia, where it forms the principal and almost daily luxury of all the people, in every rank; and it is employed as a sovereign remedy for a great variety of disorders. The Hon. Mr. Basil Cochrane has lately published a Treatise on the Vapour Bath, from which, it appears, he has brought the apparatus to such perfection, that he can apply it of all degrees of temperature, partially or generally, by shower, or by steam, with a great force or a small one; according to the particular circumstances under which patients are so variously placed, who require such assistance. See *Cochrane on Vapour Bath.* Connected with this article, is the *air-pump vapour bath;* a species of vapour bath, or machine, to which the inventor has given this name. This apparatus has been found efficacious in removing paroxysms of the gout, and preventing their recurrence; in acute and chronic rheumatism, palsy, cutaneous diseases, ulcers, &c. It has also been proposed in chilblains, leprosy, yaws, tetanus, amenorrhea, and dropsy.

II. Those applications are called *dry baths,* which are made of ashes, salt, sand, &c. The ancients had many ways of exciting a sweat, by means of a dry heat; as by the use of hot sand, stove rooms, or artificial bagnios; and even from certain natural hot steams of the earth, received under a proper arch, or hot house, as we learn from Celsus. They had also another kind of bath by insolation, where the body was exposed to the sun for some time, in order to draw forth the superfluous moisture from the inward parts; and to this day it is a practice, in some nations, to cover the body over with horse dung, especially in painful chronic diseases. In New England, they make a kind of stove of turf, wherein the sick are shut up to bathe, or sweat. It was probably from a knowledge of this practice, and of the exploded doctrines of Celsus, that the noted empiric Dr. Graham drew his notions of the sulutary effects of what he called *earth bathing;* a practice which, in the way he used it, consigned some of his patients to a perpetual mansion under the ground. The like name of *dry* bath, is sometimes also given to another kind of bath, made of kindled coals, or burning spirit of wine. The patient being placed in a convenient close chair, for the reception of the fume, which rises and provokes sweat in a plentiful manner; care being taken to keep the head out, and to secure respiration. This bath has been said to be very effectual in removing old obstinate pains in the limbs.

III. *Medicated baths* are such as are saturated with various mineral, vegetable, or sometimes animal substances. Thus we have sulphur and iron baths, aromatic and milk baths. There can be no doubt that such ingredients, if duly mixed, and a proper temperature given to the water, may, in certain complaints, be productive of effects highly beneficial. Water, impregnated with sulphate of iron, will abound with the bracing particles of that metal, and may be useful for strengthening the part to which it is applied, reinvigorating debilitated limbs, stopping various kinds of bleeding, restoring the menstrual and hæmorrhoidal discharges when obstructed, and, in short, as a substitute for the natural iron bath. There are various other medicated baths, such as those prepared with alum, and quick-lime, sal-ammoniac, &c. by boiling them together, or separately, in pure rain water. These have long been reputed as eminently serviceable in paralytic, and all other diseases arising from nervous and muscular debility.

IV. A term in chemistry, when the vessels in which bodies are exposed to the action of heat, are not placed in immediate contact with the fire, but receive the required degree of heat by another intermediate body, such apparatus is termed a bath. These have been variously named, as dry, vapour, &c. Modern chemists distinguish three kinds:

1. *Balneum arenæ,* or the sand bath. This consists merely of an open iron, or baked clay sand-pot, whose bottom is mostly convex, and exposed to the furnace. Finely sifted sea-sand is put into this, aud the vessel containing the substance to be heated, &c. in the sand bath, immersed in the middle.

2. *Balneum mariæ,* or the wather bath. This is very simple, and requires no particular apparatus. The object is to place the vessel containing the substance to be heated, in another, containing water; which last must be of such a nature as to be fitted for the application of fire, as a common still, or kettle.

3. *The vapour bath.* When any substance is heated by the steam, or vapour, of boiling water, chemists say it is done by means of a vapour bath.

Bath waters. *Bathoniæ aquæ; Solis aquæ; Badiguæ aquæ.* Bath is the name of a city in Gloucestershire that has been celebrated, for a long series of years, for its numerous hot springs, which are of a higher temperature than any in this kingdom, (from 112° to 116°;) and, indeed, are the only natural waters which we possess that are at all hot to the touch; all the other thermal waters being of a heat below the animal temperature, and only deserving that appellation from being invariably warmer than the general average of the heat of common springs. By the erection of elegant baths, these waters are particularly adapted to the benefit of invalids, who find here a variety of establishments, contributing equally to health, convenience, and amusement. There are three principal springs in the city of Bath, namely, those called the *King's Bath,* the *Cross Bath,* and the *Hot Bath;* all within a short distance of each other, and emptying themselves into the river Avon, after having passed through the several baths. Their supply is so copious, that all the large reservoirs used for bathing are filled every evening with fresh water, from their respective fountains. In their sensible and medicinal properties, there is but a slight difference. According to Dr. Falconer, the former are—1. That the water, when newly drawn, appears clear and colourless, remains perfectly inactive, without bubbles, or any sign of briskness, or effervescence. 2. After being exposed to the open air, for some hours, it becomes rather turbid, by the separation of a pale yellow, ochery precipitate, which gradually subsides. 3. No odour is perceptible from a glass of the fresh water, but a slight pungency to the taste from a large mass of it, when fresh drawn; which, however, is neither fœtid nor sulphureous. 4. When hot from the pump, it affects the mouth with a strong chalybeate impression, without being of a saline or pungent taste. And, fifthly, on growing cold, the chalybeate taste is entirely lost, leaving only a very slight sensation on the tongue, by which it can scarcely be distinguished from common hard spring-water. The temperature of the King's Bath water, which is usually preferred for drinking, is, when fresh drawn in the glass, above 116°; that of the Cross Bath, 112°. But, after flowing into the spacious bathing vessels, it is generally from 100 to 106° in the hotter baths, and from 92 to 94° in the Cross Bath; a temperature which remains nearly stationary, and is greater than that of any other natural spring in Britain. A small quantity of gas is also disengaged from these waters, which Dr. Priestly first discovered to contain no more than one-twentieth part of its bulk of fixed air, or carbonic acid. The chemical properties of the Bath waters, according to the most accurate analysers, Doctors Lucas, Falconer, and Gibbs, contain so small a proportion of iron, as to amount only to one-twentieth or one-thirty-eighth of a grain in the pint; and, according to Dr. Gibbs, fifteen grains and a quarter of siliceous earth in the gallon. Dr. Saunders estimates a gallon of the King's Bath water to contain about eight cubic inches of carbonic acid, and a similar quantity of air, nearly azotic, about eighty grains of solid ingredients, one-half of which probably consists of sulphurate and muriate of soda, fifteen grains and a half of silicious earth, and the remainder is selenite, carbonate of lime, and so small a portion of oxyde of iron as to be scarcely calculable. Hence he concludes, that the King's Bath water is the strongest chalybeate; next in order, the Hot Bath water; and lastly, that of the Cross Bath, which contains the smallest proportions of chalybeate, gaseous and saline, but considerably more of the earthy particles; while its water, in the pump, is also two degrees lower than that of the others. It is likewise now ascertained, that these springs do not exhibit the slightest traces of sulphur, though it was formerly believed, and erroneously supported on the authority of Dr. Charleton, that the subtile aromatic vapour in the Bath waters, was a sulphurous principle, entirely similar to common brimstone.

With regard to the effect of the Bath waters on the human system, independent of their specific properties, as a medicinal remedy not to be imitated completely by any chemical process, Dr. Saunders attributes much of their salubrious influence to the natural degree of warmth peculiar to these springs, which, for ages, have preserved an admirable degree of uniformity of temperature. He thinks too, that one of their most important uses is that of an external application, yet supposes that, in this respect, they differ little from common water, when heated to the same temperature, and applied under similar circumstances.

According to Dr. Falconer, the Bath water, when drunk fresh from the spring, generally raises, or rather accelerates the pulse, increases the heat, and promotes the different secretions. These symptoms in most cases, become perceptible soon after drinking it, and will sometimes continue for a considerable time. It is, however, remarkable, that they are only produced in invalids. Hence we may conclude, that these waters not only possess heating properties, but their internal use is likewise attended with a peculiar stimulus, acting more immediately on the nerves.

One of the most salutary effects of the Bath water, consists in its action on the urinary organs, even when taken in moderate doses. Its operation on the bowels varies in different individuals, like that of all other waters, which do not contain any cathartic salt; but, in general, it is productive of costiveness: an effect resulting from the want of an active stimulus to the intestines, and probably also from the determination this water occasions to the skin, more than from any astringency which it may possess; for, if perspiration be suddenly checked during the use of it, a diarrhœa is sometimes the consequence. Hence it appears that its stimulant powers are primarily, and more particularly exerted in the stomach, where it produces a variety of symptoms, sometimes slight and transient, but, occasionally, so considerable and permanent, as to require it to be discontinued. In those individuals with whom it is likely to agree, and prove beneficial, the Bath waters excite, at first, an agreeable glowing sensation in the stomach, which is speedily followed by an increase both of appetite and spirits, as well as a quick secretion of urine. In others, when the use of them is attended with head-ache, thirst, and constant dryness of the tongue, heaviness, loathing of the stomach, and sickness; or if they are not evacuated, either by urine or an increased perspiration, it may be justly inferred that their further continuance is improper.

The diseases for which these celebrated waters are resorted to, are very numerous, and are some of the most important and difficult of cure of all that come under medical treatment. In most of them, the bath is used along with the waters, as an internal medicine. The general indications, of the propriety of using this medicinal water, are in those cases where a gentle, gradual, and permanent stimulus, is required. Bath water may certainly be considered as a chalybeate, in which the iron is very small in quantity, but in a highly active form; and the degree of temperature is in itself a stimulus, often of considerable powers. These circumstances again point out the necessity of certain cautions, which, from a view of the mere quantity of foreign contents, might be thought superfluous. Although, in estimating the powers of this medicine, allowance must be made for local prejudice in its favour, there can be no doubt but that its employment is hazardous, and might often do considerable mischief, in various cases of active inflammation, especially in irritable habits, where there exists a strong tendency to hectic fever; and even in the less inflammatory state of diseased and suppurating viscera; and, in general, wherever a quick pulse and dry tongue indicate a degree of general fever. The cases, therefore, to which this water are peculiarly suited, are mostly of the chronic kind; and by a steady perseverance in this remedy, very obstinate disorders have given way. The following, Dr. Saunders, in his Treatise on Mineral Waters, considers as the principal, viz. 1. Chlorosis, a disease which, at all times, is much relieved by steel, and will bear it, even where there is a considerable degree of feverish irritation, receives particular benefit from the Bath water; and its use, as a warm bath, excellently contributes to remove that languor of circulation, and obstruction of the natural evacuations, which constitute the leading features of this common and troublesome disorder. 2. The complicated diseases, which are often brought on by a long residence in hot climates, affecting the secretion of bile, the functions of the stomach, and alimentary canal, and which generally produce organic derangement in some part of the hepatic system, often receive much benefit from the Bath water, if used at a time when suppurative inflammation is not actually present. 3. Another and less active disease of the biliary organs, the jaundice, which arises from a simple obstruction of the gall-ducts, is still oftener removed by both the internal and external use of these waters. 4. In rheumatic complaints, the power of this water, as Dr. Charleton well observes, is chiefly confined to that species of rheumatism which is unattended with inflammation, or in which the patient's pains are not increased by the warmth of his bed. A great number of the patients that resort to Bath, especially those that are admitted into the hospital, are affected with rheumatism in all its stages; and it appears from the most respectable testimony, that a large proportion of them receive a permanent cure. (See *Falconer on Bath Water in Rheumatic Cases.*) 5. In gout, the greatest benefit is derived from this water, in those cases where it produces anomalous affections of the head, stomach, and bowels; and it is here a principal advantage to be able to bring, by warmth, that active local inflammation in any limb, which relieves all the other troublesome and dangerous symptoms. Hence it is that Bath water is commonly said to produce the gout; by which is only meant that, where persons have a gouty affection, shifting from place to place, and thereby much disordering the system, the internal and external use of the Bath water will soon bring on a general increase of action, indicated by a flushing in the face, fulness in the circulating vessels, and relief of the dyspeptic symptoms; and the whole disorder will terminate in a regular fit of the gout in the extremities, which is the crisis always to be wished for. 6. The colica pictonum, and the paralysis, or loss of nervous power in particular limbs, which is one of its most serious consequences, is found to be peculiarly relieved by the use of the Bath waters, more especially when applied externally, either generally, or upon the part affected.

The quantity of water taken daily, during a full course, and by adults, is recommended by Dr. Falconer, not to exceed a pint and a half, or two pints; and in chlorosis, with irritable habits, not more than one pint is employed; and when the bath is made use of, it is generally two or three times a week, in the morning. The Bath waters require a considerable time to be persevered in, before a full and fair trial can be made. Chronic rheumatism, habitual gout, dyspepsia, from a long course of high and intemperate living, and the like, are disorders not to be removed by a short course of any mineral water, and many of those who have once received benefit at the fountains, find it necessary to make an annual visit to them, to repair the waste in health during the preceding year.

Bath, cauteres. A sulphureous bath near Barege, which raises the mercury in Fahrenheit's thermometer to 131°.

Bath, St. Saviour's. A sulphureous and alkaline bath, in the valley adjoining Barege, the latter of which raises Fahrenheit's thermometer as high as 131°. It is much resorted to from the South of France, and used chiefly externally, as a simple thermal water.

Bath, cold. See *Bath.*

Bath, hot. See *Bath.*

Bath, tepid. See *Bath.*

Bath, vapour. See *Bath.*

Ba′thmis. (From βαινω, to enter.) *Bathmus.* The seat, or base; the cavity of a bone, with the protuberance of another, particularly those at the articulation of the humerus and ulna, according to Hippocrates and Galen.

Batho′niæ aquæ. See *Bath waters.*

Ba′thron. (From βαινω, to enter.) *Bathrum.* The same as bathmis; also an instrument used in the extension of fractured limbs, called *scamnum.* —*Hippocrates.* It is described by Oribasius and Scultetus.

Ba′tia. A retort. Obsolete.

Bati′non-moron. (From βατος, a bramble, and μορον, a raspberry.) The raspberry.

Batra′chium. (From βατραχος, a frog; so called from its likeness to a frog.) The herb crow's foot, or ranunculus.

BA′TRACHUS. (From βατραχος, a frog; so called because they who are infected with it croak like a frog.) An inflammatory tumour under the tongue. See *Ranula.*

Battari′smus. (From βαττος, a Cyrenæan prince, who stammered.) Stammering; a defect in pronunciation. See *Psellismus.*

Batta′ta virginiana. See *Solanum tuberosum*, and *Convolvulus batatas.*

Batta′ta peregrina. The cathartic potatoe; perhaps a species of *ipomæa.* If about two ounces of them are eaten at bed-time, they greatly move the belly the next morning.

BATTIE, William, was born in Devonshire, in 1704. He graduated at Cambridge, and after practising some years successfully at Uxbridge, settled in London, and became a fellow of the College of Physicians, as well as of the Royal Society. The insufficiency of Bethlehem hospital to receive all the indigent objects labouring under insanity in this metropolis, naturally led to the establishment of another similar institution; and Dr. Battie having been very active in promoting the subscription for that purpose, he was appointed physician to the new institution, which was called St. Luke's hospital, then situated on the north side of Moorfields. In 1757 he published a treatise on madness; and a few years after, having exposed before the House of Commons, the abuses often committed in private madhouses, they became the subject of legislative interference, and were at length placed under the control of the College of Physicians, and the magistrates in the country. He died at the age of 72.

Bau′da. A vessel for distillation was formerly so called.

BAUHIN, John, was born at Lyons, in 1541. Being greatly attached to botany, he accompanied the celebrated Gesner in his travels through several countries of Europe, and collected abundant materials for his principal work, the "Historia Plantarum," which contributed greatly to the improvement of his favourite science. He was, at the age of 32, appointed physician to the duke of Wirtemberg, and died in 1613. A Treatise on Mineral Waters, and some other publications by him also remain.

BAUHIN, Gaspard, was brother to the preceding, but younger by 20 years. He graduated at Basle, after studying at several universities, and was chosen Greek professor at the early age of 22; afterwards professor of anatomy and botany; then of medicine, with other distinguished honours, which he retained till his death in 1624. Besides the plants collected by himself, he received material assistance from his pupils and friends, and was enabled to add considerably to the knowledge of botany; on which subject, as well as anatomy, he has left numerous publications. Among other anatomical improvements, he claims the discovery of the valve of the colon. His "Pinax" contains the names of six thousand plants mentioned by the ancients, tolerably well arranged; and being continually referred to by Linnæus, must long retain its value.

BAULMONEY. See *Æthusa meum.*

BAUME, Anthony, an apothecary, born at Senlis in 1728. He distinguished himself at an early age by his skill in chemistry and pharmacy: and was afterwards admitted a member of the Royal Academy of Sciences of Paris. He also gave lectures on chemistry for several years with great credit. Among other works, he published "Elements of Pharmacy," and a "Manual of Chemistry," which met with considerable approbation: also a detailed account of the different kinds of soil, and the method of improving them for the purposes of agriculture.

Bau'rach. (Arab. *Bourach.*) A name formerly applied to nitre, borax, soda, and many other salts.

Baxa'na. (Indian.) *Rabuxit.* A poisonous tree growing near Ormuz.

BAY. A name of several articles; as bay-cherry, bay-leaf, bay-salt, &c.

Bay-cherry. See *Prunus Lauro-cerasus.*

Bay-leaves. See *Laurus.*

Bay-leaved Passion-flower. See *Passiflora laurifolia.*

Bay-salt. A very pure salt prepared from sea-water by spontaneous evaporation.

Ba'zcher. A Persian word for antidote.

Bde'lla. (From βδαλλω, to suck.) *Bdellerum.* A horse-leech.

BDE'LLIUM. (From *bedallah,* Arab.) *Adrobolon; Madeleon; Bolchon; Balchus.* Called by the Arabians, *Mokel.* A gum resin, like very impure myrrh. The best bdellium is of a yellowish brown, or dark-brown colour, according to its age; unctuous to the touch, brittle, but soon softening, and growing tough betwixt the fingers; in some degree transparent, not unlike myrrh; of a bitterish taste, and a moderately strong smell. It does not easily take flame, and, when set on fire, soon goes out. In burning it sputters a little, owing to its aqueous humidity. Its sp. grav. is 1.371. Alkohol dissolves about three-fifths of bdellium, leaving a mixture of gum and cerasin. Its constituents, according to Pelletier, are 59 resin, 9.2 gum, 30.6 cerasin, 1.2 volatile oil and loss. It is one of the weakest of the deobstruent gums. It was sometimes used as a pectoral and an emmenagogue. Applied externally, it is stimulant, and promotes suppuration. It is never met with in the shops of this country.

Bde'llus. (From βδεω, to break wind.) A discharge of wind by the anus.

Bdely'gmia. (From βδεω, to break wind.) Any filthy and nauseous odour.

BEAK. See *Rostrum.*

BEAN. See *Vicia faba.*

Bean, French. See *Phaseolus vulgaris.*

Bean, Kidney. See *Phaseolus vulgaris.*

Bean, Malacca. See *Avicennia tomentosa.*

Bean of Carthagena. See *Bejuio.*

Bean, St. Ignatius. See *Ignatia amara.*

BEAR. *Ursa.* The name of a well-known animal. Several things are designated after it, or a part of it.

Bear's berry. See *Arbutus uva ursi.*

Bear's bilberry. See *Arbutus uva ursi.*

Bear's breech. See *Acanthus.*

Bear's foot. See *Helleborus fœtidus.*

Bear's whortleberry. See *Arbutus uva ursi.*

Bear's whorts. See *Arbutus uva ursi.*

BEARD. 1. The hair growing on the chin and adjacent parts of the face, in adults of the male sex.

2. In botany. See *Barba; Arista.*

Be'cca. A fine kind of resin from the turpentine and mastich trees of Greece and Syria, formerly held in great repute.

BECCABU'NGA. (From *bach bungen,* water-herb, German, because it grows in rivulets.) See *Veronica beccabunga.*

Be'cha. See *Bechica.*

BE'CHICA. (*Bechicus;* from βηξ, a cough.) *Bechita.* Medicines to relieve a cough. An obsolete term. The *trochisci bechici albi* consist of starch and liquorice, with a small proportion of Florentine orris root made into lozenges, with mucilage of gum tragacanth. They are a soft pleasant demulcent. The *trochisci bechici nigri* consist chiefly of the juice of liquorice, with sugar and gum-tragacanth.

Be'chion. (From βηξ, a cough; so called from its supposed virtues in relieving coughs.) See *Tussilago farfara.*

Becui'ba nux. A large nut growing in Brasil, from which a balsam is drawn that is held in estimation in rheumatisms.

Bede'guar. (Arabian.) *Bedeguar.* The *Carduus lacteus syriacus* is so called, and also the *Rosa canina.*

Bedengian. The name of the love-apples in Avicenna.

BEDSTRAW. See *Galium aparine.*

BEE. See *Apis mellifica.*

BEECH. See *Fagus.*

BEER. The wine of grain made from malt and hops in the following manner. The grain is steeped for two or three days in water, until it swells, becomes somewhat tender, and tinges the water of a bright reddish-brown colour. The water being then drained away, the barley is spread about two feet thick upon a floor, where it heats spontaneously, and begins to grow, by first shooting out the radicle. In this state the germination is stopped by spreading it thinner, and turning it over for two days; after which it is again made into a heap, and suffered to become sensibly hot, which usually happens in little more than a day. Lastly, it is conveyed to the kiln, where, by a gradual and low heat, it is rendered dry and crisp. This is malt; and its qualities differ according as it is more or less soaked, drained, germinated, dried, and baked. In this, as in other manufactories, the intelligent operators often make a mystery of their processes, from views of profit; and others pretend to peculiar secrets who really possess none.

Indian corn, and probably all large grain, requires to be suffered to grow into the blade, as well as root, before it is fit to be made into malt. For this purpose it is buried about two or three inches deep in the ground, and covered with loose earth; and in ten or twelve days it springs up. In this state it is taken up and washed, or fanned, to clear it from its dirt; and then dried in the kiln for use.

Barley, by being converted into malt, becomes one-fifth lighter, or 20 per cent.; 12 of which are owing to kiln-drying, 1.5 are carried off by the steep-water, 3 dissipated on the floor, 3 loss in cleaning the roots, and 0.5 waste or loss.

The degree of heat to which the malt is exposed in this process, gradually changes its colour from very pale to actual blackness, as it simply dries it, or converts it to charcoal.

The colour of the malt not only affects the colour of the liquor brewed from it; but, in consequence of the chemical operation, of the heat applied, on the principles that are developed in the grain during the process of malting, materially alters the quality of the beer, especially with regard to the properties of becoming fit for drinking and growing fine.

Beer is made from malt previously ground, or cut to pieces by a mill. This is placed in a tun, or tub with a false bottom; hot water is poured upon it, and the whole stirred about with a proper instrument. The temperature of the water in this operation, called Mashing, must not be equal to boiling; for, in that case, the malt would be converted into a paste, from which the impregnated water could not be separated. This is called Setting. After the infusion has remained for some time upon the malt, it is drawn off, and is then distinguished by the name of Sweet Wort. By one or more subsequent infusions of water, a quantity of weaker wort is made, which is either added to the foregoing, or kept apart, according to the intention of the operator. The wort is then boiled with hops, which gives it an aromatic bitter taste, and is supposed to render it less liable to be spoiled in keeping; after which it is cooled in shallow vessels, and suffered to ferment, with the addition of a proper quantity of yeast. The fermented liquor is beer; and differs greatly in its quality, according to the nature of the grain, the malting, the mashing, the quantity and kind of the hops and the yeast, the purity or admixtures of the water made use of, the temperature and vicissitudes of the weather, &c.

Beside the various qualities of malt liquors of a similar kind, there are certain leading features by which they are distinguished, and classed under different names, and to produce which, different modes of management must be pursued. The principal distinctions are into beer, properly so called; ale; table or small beer; and porter, which is commonly termed beer in London. Beer is a strong, fine, and thin liquor; the greater part of the mucilage having been separated by boiling the wort longer than for ale, and carrying the fermentation farther, so as to convert the saccharine matter into alcohol. Ale is of a more syrupy consistence, and sweeter taste; more of the mucilage being retained in it, and the fermentation not having been carried so far as to decompose all the sugar. Small beer, as its name implies, is a weaker liquor; and is made, either by adding a large portion of water to the malt, or by mashing with a fresh quantity of water what is left after the beer or ale wort is drawn off. Porter was probably made originally from very high dried malt; but it is said, that its peculiar flavour cannot be imparted by malt and hops alone.

Mr. Brande obtained the following quantities of alkohol from 100 parts of different species of beers. Burton ale, 8.88; Edinburgh ale, 6.2; Dorchester ale, 5.56; the average being = 6.87. Brown stout, 6.8; London Porter (average) 4.2; London small beer (average) 1.28.

As long ago as the reign of Queen Anne, brewers were forbid to mix sugar, honey, Guinea pepper, essentia bina, cocculus indicus, or any other unwholesome ingredient, in beer, under a certain penalty; from which we may infer, that such at least was the practice of some; and writers, who profess to discuss the secrets of the trade, mention most of these, and some other articles as essentially necessary. The essentia bina is sugar boiled down to a dark colour, and empyreumatic flavour. Broom tops, wormwood, and other bitter plants, were formerly used to render beer fit for keeping, before hops were introduced into this country; but are now prohibited to be used in beer made for sale.

By the present law of this country, nothing is allowed to enter into the composition of beer, except malt and hops. Quassia and wormwood are often fraudulently introduced; both of which are easily discoverable by their nauseous bitter taste. They form a beer which does not preserve so well as hop beer. Sulphate of iron, alum, and salt, are often added by the publicans, under the name of *beer heading*, to impart a frothing property to beer, when it is poured out of one vessel into another. Molasses and extract of gentian root are added with the same view. Capsicum, grains of paradise, ginger root, coriander seed, and orange peel, are also employed to give pungency and flavour to weak or bad beer. The following is a list of some of the unlawful substances seized at different breweries, and brewers' druggists' laboratories, in London, as copied from the minutes of the committee of the House of Commons. Cocculus indicus multum, (an extract of the cocculus,) colouring, honey, hartshorn shavings, Spanish juice, orange powder, ginger, grains of paradise, quassia, liquorice, caraway seeds, copperas, capsicum, mixed drugs. Sulphuric acid is very frequently added to *bring beer forward*, or make it hard, giving new beer instantly the taste of what is 18 months old. According to Mr. Accum, the present *entire* beer of the London brewer is composed of all the waste and spoiled beer of the publicans, the bottoms of butts, the leavings of the pots, the drippings of the machines for drawing the beer, the remnants of beer that lay in the leaden pipes of the brewery, with a portion of brown stout, bottling beer, and mild beer. He says that opium, tobacco, nux vomica, and extract of poppies, have been likewise used to adulterate beer. By evaporating a portion of beer to dryness, and igniting the residuum with chlorate of potassa, the iron of the copperas will be procured in an insoluble oxyde. Muriate of barytes will throw down an abundant precipitate from beer contaminated with sulphuric acid or copperas; which precipitate may be collected, dried, and ignited. It will be insoluble in nitric acid.

Beer appears to have been of ancient use, as Tacitus mentions it among the Germans, and has been usually supposed to have been peculiar to the northern nations; but the ancient Egyptians, whose country was not adapted to the culture of the grape, had also contrived this substitute for wine; and Mr. Park has found the art of making malt, and brewing from it very good beer, among the negroes in the interior parts of Africa. See *Wheat.*

Bees' wax. See *Cera.*

BEET. See *Beta.*

Beet, red. See *Beta.*

Beet, white. A variety of red beet. The juice and powder of the root are said to be good to excite sneezing, and will bring away a considerable quantity of mucus.

BE'GMA. (From *βησσω*, to cough.) A cough; also expectorated mucus, according to Hippocrates.

BE'HEN. The Arabian for finger.

BEHEN ALBUM. (From *behen*, a finger, Arabian.) See *Centaurea behen.*

BEHEN OFFICINARUM. See *Cucubalus behen.*

BEHEN RUBRUM. See *Statice Limonium.*

BEIDE'LSAR. *Beidellopar.* A species of Asclepias, used in Africa as a remedy for fever and the bites of serpents. The caustic juice which issues from the roots when wounded, is used by the negroes to destroy venereal and similar swellings.

BEJU'IO. *Habilla de Carthagena.* Bean of Carthagena. A kind of bean in South America, famed for being an effectual antidote against the poison of all serpents, if a small quantity is eaten immediately. This bean is the peculiar product of the jurisdiction of Carthagena.

BELA-AYE. (An Indian word.) See *Nerium antidysentericum.*

BELEMNOI'DES. (From *βελεμνον*, a dart, and *ειδος*, form; so named from their dart-like shape.) *Belonoides; Beloidos.* The styloid process of the temporal bone, and the lower end of the ulna, were formerly so called.

BELE′SON. (An Indian word.) *Belilia.* See *Mussenda frondosa.*

BELL METAL. A mixture of tin and copper.

BELLADO′NNA. (From *bella donna*, Italian, a handsome lady; so called because the ladies of Italy use it, to take away the too florid colour of their faces.) See *Atropa belladonna.*

BE′LLEGU. See *Mirobalanus bellirica.*

BELLERE′GI. See *Myrobalanus bellirica.*

BELLE′RICÆ. See *Myrobalanus bellirica.*

BELLIDIOI′DES. (From *bellis*, a daisy, and ειδος, form.) See *Chrysanthemum.*

BELLI′NI, LAURENCE, an ingenious physician, born at Florence in 1643. He was greatly attached to the mathematics, of which he was made professor at Pisa, when only twenty years of age. He was soon after appointed professor of anatomy, which office he filled with credit for nearly thirty years. He was one of the chief supporters of the mathematical theory of medicine, which attempted to explain the functions of the body, the causes of diseases, and the operations of medicines on mechanical principles; and having imprudently regulated his practice accordingly, he was generally unsuccessful, and lost the confidence of the public, as well as of Cosmo III. of Florence, who had appointed him his physician. In his anatomical researches he was more successful, having first accurately described the nervous papillæ of the tongue, and discovered them to be the organ of taste; and also having made better known the structure of the kidney. He was author of several other publications, and died in 1704.

BE′LLIS. (*à bello colore*, from its fair colour.) The name of a genus of plants in the Linnæan system. Class, *Syngenesia*; Order, *Polygamia superflua.* The daisy.

BELLIS MAJOR. See *Chrysanthemum.*

BELLIS MINOR. See *Bellis perennis.*

BELLIS PERENNIS. The systematic name of the common daisy. *Bellis; Bellis minor; Bellis perennis—scapo nudo*, of Linnæus, or bruisewort, was formerly directed in pharmacopœias by this name. Although the leaves and flowers are rather acrid, and are said to cure several species of wounds, they are never employed by modern surgeons.

BELLO′CULUS. (From *bellus*, fair, and *oculus*, the eye.) A precious stone, resembling the eye, and formerly supposed to be useful in its disorders.

BE′LLON. The Colica pictonum.

BELLONA′RIA. (From *Bellona*, the goddess of war.) An herb which, if eaten, makes people mad, and act outrageously, like the votaries of Bellona.

BELLOSTE, AUGUSTIN, a surgeon, born at Paris in 1654. After practising several years there, and as an army surgeon, he was invited to attend the mother of the Queen of Sardinia, and continued at Turin till his death in 1730. He was inventor of a mercurial pill, called by his name, by which he is said to have acquired a great fortune. The work by which he is principally known, is called the "Hospital Surgeon," which passed through numerous editions, and was translated into most of the European languages. Among other useful observations, he recommended piercing carious bones, to promote exfoliation, which indeed Celsus had advised before; and he blamed the custom of frequently changing the dressings of wounds, as retarding the cure.

BELLU′TTA TSJAMPACAM. (Indian.) A tree of Malabar, to which many virtues are attributed.

BELMU′SCHUS. A name of the Abelmoschus. See *Hibiscus abelmoschus.*

BE′LNILEG. See *Myrobalanus Bellirica.*

BELO′ERE. (Indian.) An evergreen plant of America, the seeds of which purge moderately, but the leaves roughly.

BELONOI′DES. See *Belemnoides.*

BELU′LCUM. (From βελος, a dart, and ελκω, to draw out.) A surgeon's instrument for extracting thorns, or darts.

BELU′ZZAR. *Beluzaar.* The Chaldee word for antidote.

BELZO′E. See *Styrax benzoin.*

BELZOI′NUM. See *Styrax benzoin.*

BEM-TA′MARA. The faba Ægyptiaca.

BEN. An Arabian word formerly very much used. See *Guilandina moringa.*

BEN MAGNUM. Monardus calls a species of esula, or garden spurge, by this name, which purges and vomits violently.

BEN TAMARA. The Egyptian bean.

BE′NATH. (Arabian.) Small pustules produced by sweating in the night.

BE′NEDICT. *Benedictus.* A specific name prefixed to many compositions and herbs on account of their supposed good qualities; as *Benedicta herba; Benedicta aqua*, &c.

BENEDICTA AQUA. Many compound waters have been so called, especially lime-water, and a water distilled from *Serpyllum.* In Schroeder, it is the name for an emetic.

BENEDICTA HERBA. See *Geum urbanum.*

BENEDICTA LAXATIVA. A compound of turbeth, scammony, and spurges, with some warm aromatics.

BENEDICTUM LAXATIVUM. Rhubarb, and sometimes the lenitive electuary.

BENEDICTUM LIGNUM. Guaiacum.

BENEDICTUM VINUM. Antimonial wine.

BENEDI′CTUS. (From *benedico*, to bless.) See *Benedict.*

BENEDICTUS CARDUUS. See *Centaurea benedicta.*

BENEDICTUS LAPIS. A name for the philosopher's stone.

BENEOLE′NTIA. (From *bene*, well, and *oleo*, to smell.) Sweet-scented medicines.

BENG. A name given by the Mahomedans to the leaves of hemp, formed into pills, or conserve. They possess exhilarating and intoxicating powers.

Bengal quince. See *Erateva marmelos.*

BENGA′LÆ RADIX. (From *Bengal*, its native place.) See *Cassumuniar.*

BENGA′LLE INDORUM. (From *Bengal*, its native place.) See *Cassumuniar.*

BE′NGI EIRI. A species of evergreen. Indian *ricinus*, which grows in Malabar.

BENIT. See *Geum urbanum.*

BENI′VI ARBOR. See *Styrax benzoin.*

BENJAMIN. See *Styrax benzoin.*

Benjamin flowers. See *Benzoic acid.*

BENZO′AS. A benzoate. A salt formed by the union of benzoic acid, with salifiable bases; as benzoate of alumine, &c.

BENZO′E. See *Styrax benzoin.*

BENZOE AMYGDALOIDES. See *Styrax benzoin.*

BENZOES FLORES. See *Benzoic acid.*

BENZO′IC ACID. See *Acidum benzoicum.* "This acid was first described in 1608, by Blaise de Vigenere, in his Treatise on Fire and Salt, and has been generally known since by the name of flowers of benjamin or benzoin, because it was obtained by sublimation from the resin of this name. As it is still most commonly procured from this substance, it has preserved the epithet of benzoic, though known to be a peculiar acid, obtainable not from benzoin alone, but from different vegetable balsams, vanello, cinnamon, ambergris, the urine of children, frequently that of adults, and always, according to Fourcroy and Vauquelin, though Giese denies this, from that of quadrupeds living on grass and hay, particularly the camel, the horse, and the cow. There is reason to conjecture that many vegetables, and among them some of the grasses, contain it, and that it passes from them into the urine. Fourcroy and Vauquelin found it combined with potassa and lime in the liquor of dunghills, as well as in the urine of the quadrupeds above mentioned; and they strongly suspect it to exist in the *Anthoxanthum odoratum*, or sweet-scented vernal-grass, from which hay principally derives its fragrant smell. Giese, however, could find none either in this grass or in oats.

The usual method of obtaining it affords a very elegant and pleasing example of the chemical process of sublimation. For this purpose a thin stratum of powdered benzoin is spread over the bottom of a glazed earthen pot, to which a tall conical paper covering is fitted: gentle heat is then to be applied to the bottom of the pot, which fuses the benzoin, and fills the apartment with a fragrant smell, arising from a portion of essential oil and acid of benzoin, which are dissipated into the air, at the same time the acid itself rises very suddenly in the paper head, which may be occasionally inspected at the top, though with some little care, because the fumes will excite coughing. This saline sublimate is condensed in the form of long needles, or straight filaments of a white colour, crossing each other in all directions. When the acid ceases to rise, the cover may be changed, a new one applied, and the heat raised: more flowers of a yellowish colour will then rise, which require a second sublimation to deprive them of the empyreumatic oil they contain.

The sublimation of the acid of benzoin may be conveniently performed by substituting an inverted earthen pan instead of the paper cone. In this case the two pans should be made to fit, by grinding on a stone with sand, and they must be luted together with paper dipped in paste. This method seems preferable to the other, where the presence of the operator is required elsewhere; but the paper head can be more easily inspected and changed. The heat applied must be gentle, and the vessels ought not to be separated till they have become cool.

The quantity of acid obtained in these methods differs according to the management, and probably also from difference of purity, and in other respects, of the resin itself. It usually amounts to no more than about one-eighth part of the whole weight. Indeed Scheele says, not more than a tenth or twelfth. The whole acid of benzoin is obtained with greater certainty in the humid process of Scheele: this consists in boiling the powdered balsam with lime water, and afterwards separating the lime by the addition of muriatic acid. Twelve ounces of water are to be poured upon four ounces of slaked lime; and, after the ebullition is over, eight pounds or ninety-six ounces, more of water are to be added; a pound of finely-powdered benzoin being then put into a tin vessel, six ounces of the lime water are to be added, and mixed well with the powder; and afterwards the rest of the lime water in the same gradual manner, because the benzoin would coagulate into a mass, if the whole were added at once. This mixture must be gently boiled for half an hour with constant agitation, and afterwards suffered to cool and subside during an hour. The supernatant liquor must be decanted, and the residuum boiled with eight pounds more of lime water; after which the same process is to be once more repeated: the remaining powder must be edulcorated on the filter by affusions of hot water. Lastly, all the decoctions, being mixed together, must be evaporated to two pounds, and strained into a glass vessel. This fluid consists of the acid of benzoin combined with lime. After it is become cold, a quantity of muriatic acid must be added, with constant stirring, until the fluid tastes a little sourish. During this time the last mentioned acid unites with the lime, and forms a soluble salt, which remains suspended, while the less soluble acid of benzoin, being disengaged, falls to the bottom in powder. By repeated affusions of cold water upon the filter, it may be deprived of the muriate of lime and muriatic acid with which it may happen to be mixed. If it be required to have a shining appearance, it may be dissolved in a small quantity of boiling water, from which it will separate in silky filaments by cooling. By this process the benzoic acid may be procured from other substances, in which it exists.

Mr. Hatchell has shown that, by digesting benzoin in hot sulphuric acid, very beautiful crystals are sublimed. This is perhaps the best process for extracting the acid. If we concentrate the urine of horses or cows, and pour muriatic acid into it, a copious precipitate of benzoic acid takes place. This is the cheapest source of it."—*Ure's Chem. Dict.*

As an economical mode of obtaining this acid, Fourcroy recommends the extraction of it from the water that drains from dunghills, cowhouses, and stables, by means of the muriatic acid, which decomposes the benzoate of lime contained in them, and separates the benzoic acid, as in Scheele's process. He confesses the smell of the acid thus obtained differs a little from that of the acid extracted from benzoin; but this, he says, may be remedied, by dissolving the acid in boiling water, filtering the solution, letting it cool, and thus suffering the acid to crystallise, and repeating this operation a second time.

The acid of benzoin is so inflammable, that it burns with a clear yellow flame without the assistance of a wick. The sublimed flowers in their purest state, as white as ordinary writing paper, were fused into a clear transparent yellowish fluid, at the two hundred-and-thirtieth degree of Fahrenheit's thermometer, and at the same time began to rise in sublimation. It is probable that a heat somewhat greater than this may be required to separate it from the resin. It is strongly disposed to take the crystalline form in cooling. The concentrated sulphuric and nitric acids dissolve this concrete acid, and it is again separated without alteration, by adding water. Other acids dissolve it by the assistance of heat, from which it separates by cooling, unchanged. It is plentifully soluble in ardent spirit, from which it may likewise be separated by diluting the spirit with water. It readily dissolves in oils, and in melted tallow. If it be added in a small proportion to this last fluid, part of the tallow congeals before the rest, in the form of white opaque clouds. If the quantity of acid be more considerable, it separates in part by cooling, in the form of needles or feathers. It did not communicate any considerable degree of hardness to the tallow, which was the object of this experiment. When the tallow was heated nearly to ebullition, it emitted fumes which affected the respiration, like those of the acid of benzoin, but did not possess the peculiar and agreeable smell of that substance, being probably the sebacic acid. A stratum of this tallow, about one-twentieth of an inch thick, was fused upon a plate of brass, together with other fat substances, with a view to determine its relative disposition to acquire and retain the solid state. After it had cooled, it was left upon the plate, and, in the course of some weeks, it gradually became tinged throughout of a bluish-green colour. If this circumstance be not supposed to have arisen from a solution of the copper during the fusion, it seems a remarkable instance of the mutual action of two bodies in the solid state, contrary to that axiom of chemistry which affirms, that bodies do not act on each other, unless one or more of them be in the fluid state. Tallow itself, however, has the same effect.

Pure benzoic acid is in the form of a light powder, evidently crystallised in fine needles, the figure of which is difficult to be determined from their smallness. It has a white and shining appearance; but when contaminated by a portion of volatile oil, is yellow or brownish. It is not brittle as might be expected from its appearance, but has rather a kind of ductility and elasticity, and, on rubbing in a mortar, becomes a sort of paste. Its taste is acrid, hot, acidulous, and bitter. It reddens the infusion of litmus, but not syrup of violets. It has a peculiar aromatic smell, but not strong unless heated. This, however, appears not to belong to the acid; for Mr. Giese informs us, that on dissolving the benzoic acid in as little alkohol as possible, filtering the solution, and precipitating by water, the acid will be obtained pure, and void of smell, the odorous oil remaining dissolved in the spirit. Its specific gravity is 0.667. It is not perceptibly altered by the air, and has been kept in an open vessel twenty years without losing any of its weight. None of the combustible substances have any effect on it; but it may be refined by mixing it with charcoal powder and subliming, being thus rendered much whiter and better crystallised. It is not very soluble in water. Wenzel and Lichtenstein say four hundred parts of cold water dissolve but one, though the same quantity of boiling water dissolves twenty parts, nineteen of which separate on cooling.

The benzoic acid unites without much difficulty with the earthy and alkaline bases. These compounds are called *benzoates.*

The *benzoate of barytes* is soluble, crystallises tolerably well, is not affected by exposure to the air, but is decomposable by fire, and by the stronger acids. That of *lime* is very soluble in water, though much less in cold than in hot, and crystallises on cooling. It is in like manner decomposable by the acids and by barytes. The *benzoate of magnesia* is soluble, crystallisable, a little deliquescent, and more decomposable than the former. That of *alumina* is very soluble, crystallises in dendrites, is deliquescent, has an acerb and bitter taste, and is decomposable by fire, and even by most of the vegetable acids. The *benzoate of potassa* crystallises on cooling in little compacted needles. All the acids decompose it, and the solution of barytes and lime form with it a precipitate. The *benzoate of soda* is very crystallisable, very soluble, and not deliquescent like that of potassa, but it is decomposable by the same means. It is sometimes found native in the urine of graminivorous quadrupeds, but by no means so abundantly as that of lime. The *benzoate of ammonia* is volatile, and decomposable by all the acids and all the bases. The solutions of all the benzoates, when drying on the sides of a vessel wetted with them, form dendritical crystallisations.

Trommsdorf found in his experiments, that benzoic acid united readily with *metallic oxydes.*

The benzoates are all decomposable by heat, which, when it is slowly applied, first separates a portion of the acid in a vapour, that condenses in crystals. The soluble benzoates are decomposed by the powerful acids, which separate their acid in a crystalline form.

The benzoic acid is occasionally used in medicine, but not so much as formerly; and enters into the composition of the camphorated tincture of opium of the London college, heretofore called paregoric elixir.

BENZOI'FERA. See *Styrax benzoin.*

BENZO'INUM. (From the Arabic term *benzoah.*) See *Styrax benzoin.*

BENZOINI MAGISTERIUM. Magistery, or precipitate of gum-benjamin.

BENZOINI OLEUM. Oil of benjamin.

BERBERIA. (Origin uncertain.) *Berberi.* The name of a species of disease in the genus *Synclonus* of Good's Nosology. See *Beriberia.*

BE'RBERIS. (*Berberi,* wild. Arab. used by Averrhoes, and officinal writers.)

1. The name of a genus of plants in the Linnæan system. Class, *Hexandria;* Order, *Monogynia.* The barberry, or pepperidge bush.

2. The pharmacopœial name for the barberry. See *Berberis vulgaris.*

BERBERIS GELATINA. Barberry jelly. Barberries boiled in sugar.

BERBERIS VULGARIS. The systematic name for the barberry of the pharmacopœias. *Oxycantha Galeni; Spina acida; Crespinus.* This tree, *Berberis; pedunculis racemosis, spinis triplicibus,* of Linnæus, is a native of England. The fruit, or berries, which are gratefully acid, and moderately astringent, are said to be of great use in biliary fluxes, and in all cases where heat, acrimony, and putridity of the humours prevail. The filaments of this shrub possess a remarkable degree of irritability; for on being touched near the base with the point of a pin, a sudden contraction is produced, which may be repeated several times.

BERE'DRIAS. An ointment.

BERENGA'RIUS, JAMES, born about the end of the 15th century at Carpi, in Modena, whence he is often called *Carpus.* He was one of the restorers of anatomy, of which he was professor, first at Padua, afterwards at Bologna, which he was in a few years obliged to quit, being accused of having opened the bodies of two Spaniards alive. By his numerous dissections, he corrected many previous errors concerning the structure of the human body, and paved the way for his successor Vesalius. He was among the first to use mercurial frictions in syphilis, whereby he acquired a large fortune, which he left to the Duke of Ferrara, into whose territory he retired, at his death in 1527. His principal works are an enlarged Commentary on Mundinus, and a Treatise on Fracture of the Cranium.

BERENI SECUM. See *Artemisia vulgaris.*

BERENI'CE. (The city from whence it was formerly brought.) Amber.

BERENI'CIUM. (From φερω, to bring, and νικη, victory.) A term applied by the old Greek writers to nitre, from its supposed power in healing wounds.

BERGAMO'TE. A species of citron. See *Citrus medica.*

BERGMANITE. A massive mineral of a greenish, greyish-white, or reddish colour, which fuses into a transparent glass, or a semitransparent enamel. It is found in Frederickswam, in Norway, in quartz and in felspar.

BERIBE'RI. (An Hindostan word signifying a sheep.) *Beriberia.* A species of palsy, common in some parts of the East Indies, according to Bontius. In this disease, the patients lift up their legs very much in the same manner as is usual with sheep. Bontius adds, that this palsy is a kind of trembling, in which there is deprivation of the motion and sensation of the hands and feet, and sometimes of the body.

BERKENHOUT, John, born at Leeds, about the year 1730. His medical studies were commenced late in life, having graduated at Leyden only in 1765; nor did he long continue the practice of medicine. His "Pharmacopœia Medica," however, was very much approved, and has since passed through many editions: his other medical publications are of little importance. He died in 1791.

Bermudas berry. See *Sapindus saponaria.*

Berna′rvi. An electuary.

Berrio′nis. A name of black rosin.

BERRY. See *Bacca.*

Bers. Formerly the name of an exhilarating electuary.

Be′rula. An old name for brooklime.

Be′rula gallica. Upright water parsnip.

BERYL. Aqua-marine. A precious mineral, harder than the emerald, of a green, or greenish-yellow colour, found in Siberia, France, Saxony, Brazil, Scotland and Ireland.

Bery′tion. (From *Berytius,* its inventor.) A collyrium described by Galen.

Bes. An eight-ounce measure.

Be′sachar. A sponge.

Be′sasa. Formerly applied to wild rue.

Besease. An old name for mace.

Bese′nna. (An Arabian word.) *Muscarum fungus.* Probably a sponge, which is the nidus of some sorts of flies.

Bessa′nen. (An Arabian word.) A redness of the external parts, resembling that which precedes the leprosy; it occupies the face and extremities.—*Avicenna.*

Be′sto. A name in Oribasius for a species of saxifrage.

BE′TA. (So called from the river *Bætis,* in Spain, where it grows naturally; or, according to Blanchard, from the Greek letter βηρα, which it is said to resemble when turgid with seed.) The beet.

1. The name of a genus of plants in the Linnæan system. Class, *Pentandria;* Order, *Digynia.* The beet.

2. The pharmacopœial name of the common beet. See *Beta vulgaris.*

Beta hybrida. The plant which affords the root of scarcity. *Mangel wurzel* of the Germans; a large root. It contains much of the saccharine principle, and is very nourishing. Applied externally it is useful in cleaning foul ulcers; and is a better application than the carrot.

Beta vulgaris. The systematic name for the beet of the pharmacopœias. *Beta:—floribus congestis* of Linnæus. The root of this plant is frequently eaten by the French; it may be considered as nutritious and anti-scorbutic, and forms a very elegant pickle with vinegar. The root and leaves, although formerly employed as laxatives and emollients, are now forgotten. A considerable quantity of sugar may be obtained from the root of the beet. It is likewise said, that if beet roots be dried in the same manner as malt, after the greater part of their juice is pressed out, very good beer may be made from them. It is occasionally used to improve the colour of claret.

Betele. *Bethle; Betle; Betelle.* An oriental plant, like the tail of a lizard. It is chewed by the Indians, and makes the teeth black; is cordial and exhilirating, and in very general use throughout the East. It is supposed to be the long pepper.

BETO′NICA. (Corrupted from *Vettonica,* which is derived from the *Vectones,* an ancient people of Spain.) Betony.

1. The name of a genus of plants in the Linnæan system. Class, *Didynamia;* Order, *Gymnospermia.*

2. The pharmacopœial name for the wood betony. See *Betonica officinalis.*

Betonica aquatica. See *Scrophularia aquatica.*

Betonica officinalis. The systematic name of the betony of the pharmacopœias. *Betonica purpurea; Betonica vulgaris; Cestrum; Vetonica cordi; Betonica—spica, interrupta, corollarum labii lacinia intermedia emarginata* of Linnæus. The leaves and tops of this plant have an agreeable, but weak smell; and to the taste they discover a slight warmth, accompanied with some degree of adstringency and bitterness. The powder of the leaves of betony, snuffed up the nose, provokes sneezing; and hence it is sometimes made an ingredient in sternutatory powders. Its leaves are sometimes smoked like tobacco. The roots differ greatly, in their quality, from the other parts; their taste is very bitter and nauseous; taken in a small dose, they vomit and purge violently, and are supposed to have somewhat in common with the roots of hellebore. Like many other plants, formerly in high medical estimation, betony is now almost entirely neglected. Antonius Musa, physician to the emperor Augustus, filled a whole volume with enumerating its virtues, stating it as a remedy for no less than forty-seven disorders; and hence in Italy the proverbial compliment, *You have more virtues than betony.*

Betonica pauli. A species of veronica.

Betonica vulgaris. See *Betonica officinalis.*

BETONY. See *Betonica.*

Betony, water. See *Scrophularia aquatica.*

BE′TULA. 1. The name of a genus of plants in the Linnæan system. Class, *Monœcia;* Order, *Tetrandria.* Alder and birch.

2. The pharmacopœial name of the white birch. See *Betula alba.*

Betula alba. The systematic name of the *betula* of the pharmacopœias. *Betula:—foliis ovatis, acuminatis, serratis,* of Linnæus. The juice, leaves, and bark have been employed medicinally. If the tree be bored early in the spring, there issues, by degrees, a large quantity of limpid, watery, sweetish juice: it is said that one tree will afford from one to two gallons a day. This juice is esteemed as an antiscorbutic, deobstruent, and diuretic. When well fermented, and having a proper addition of raisins in its composition, it is frequently a rich and strong liquor; it keeps better than many of the other made-wines, often for a number of years, and was formerly supposed to possess many medical virtues; but these experience does not seem to sanction; and the virtues of the alder, like those of many other simples formerly prized, have sunk into oblivion. The leaves and bark were used externally as resolvents, detergents, and antiseptics.

Betula alnus. The systematic name for the *alnus* of the pharmacopœias. The common alder.

BEX. (From βησσω, to cough.) A cough. Dr. Good, in his Nosology, has applied this term to a genus of diseases which embraces three species, *bex humida, sicca, convulsiva.*

Bexagui′llo. A name given to the white ipecacuanha, which the Spaniards bring from Peru, as the Portuguese do the brown from Brazil.

Bexu'go. The root of the *Æmatitis peruviana* of Caspar Bauhin; one drachm of which is sufficient for a purge.

Be'zahan. The fossile bezoar.

Beze'tta cœrulea. See *Croton tinctorium.*

BE'ZOAR. (From *pa-zahar*, Persian, a destroyer of poison.) *Lapis bezoardicus.* Bezoard. A preternatural or morbid concretion formed in the bodies of land-animals. Several of these kinds of substances were formerly celebrated for their medicinal virtues, and distinguished by the names of the countries from whence they came, or the animal in which they were found. There are eight kinds, according to Fourcroy, Vauquelin, and Berthollet.

1. Superphosphate of lime, which forms concretions in the intestines of many *mammalia.*

2. Phosphate of magnesia, semitransparent and yellowish, and of sp. grav. 2.160.

3. Phosphate of ammonia and magnesia. A concretion of a grey or brown colour, composed of radiations from a centre. It is found in the intestines of herbiverous animals, the elephant, horse, &c.

4. Biliary, colour reddish-brown, found frequently in the intestines and gall-bladder of oxen, and used by painters for an orange-yellow pigment. It is inspissated bile.

5. Resinous. The oriental bezoars, procured from unknown animals, belong to this class of concretions. They consist of concentric layers, are fusible, combustible, smooth, soft, and finely polished. They are composed of bile and resin.

6. Fungous, consisting of pieces of the *Boletus igniarius*, swallowed by the animal.

7. Hairy.

8. Ligniform. Three bezoars sent to Bonaparte by the King of Persia, were found by Berthollet to be nothing but woody fibre agglomerated.

Bezoars were formerly considered as very powerful alexipharmics, so much so, indeed, that other medicines, possessed, or supposed to be possessed, of alexipharmic powers, were called *bezoardics;* and so efficacious were they once thought, that they were bought for ten times their weight in gold. These virtues, however, are in the present day justly denied them, as they produce no other effects than those common to the saline particles which they contain, and which may be given to greater advantage from other sources. A composition of bezoar with absorbent powders, has been much in repute, as a popular remedy for disorders, in children, by the name of Gascoigne's powder and Gascoigne's ball; but the real bezoar was rarely, if ever, used for these, its price offering such a temptation to counterfeit it. Some have employed for this purpose, a resinous composition, capable of melting in the fire, and soluble in alcohol; but Newmann supposed that those nearest resembling it, were made of gypsum, chalk, or some other earth, to which the proper colour was imparted by some vegetable juice. We understand, however, that tobacco pipe clay, tinged with oxgall, is commonly employed, at least for the Gascoigne's powder; this giving a yellow tint to paper, rubbed with chalk, and a green to paper rubbed over with quicklime; which are considered as proofs of genuine bezoar, and which a vegetable juice would not effect.

Bezoar bovinum. Bezoar of the ox.

Bezoar germanicum. The bezoar from the alpine goat.

Bezoar hystricis. *Lapis porcinus; Lapis malacensis; Petro del porco.* The bezoar of the Indian porcupine; said to be found in the gall-bladder of an Indian porcupine, particularly in the province of Malacca. This contrete differs from others: it has an intensely bitter taste; and on being steeped in water for a very little time, impregnates the fluid with its bitterness, and with aperient, stomachic, and, as it is supposed, with alexipharmic virtues. How far it differs in virtue from the similar concretions found in the gall-bladder of the ox, and other animals, does not appear.

Bezoar microcosmicum. The caculus found in the human bladder.

Bezoar occidentale. Occidental bezoar. This concretion is said to be found in the stomach of an animal of the stag or goat kind, a native of Peru, &c. It is of a larger size than the oriental bezoar, and sometimes as large as a hen's egg; its surface is rough, and the colour green, greyish, or brown.

Bezoar orientale. *Lapis bezoar orientalis.* Oriental bezoar stone. This concretion is said to be found in the pylorus, or fourth stomach of an animal of the goat kind, which inhabits the mountains of Persia. It is generally about the size of a kidney bean, of a roundish or oblong figure, smooth, and of a shining olive or dark-greenish colour.

Bezoar porcinum. See *Bezoar hystricis.*

Bezoar simiæ. The bezoar from the monkey.

Bezoardica radix. See *Dorstenia.*

Bezoardicum joviale. Bezoar with tin. It differed very little from the *Antihecticum Poterii.*

Bezoardicum lunale. A preparation of antimony and silver.

Bezoardicum martiale. A preparation of iron and antimony.

Bezoardicum minerale. A preparation of antimony, made by adding nitrous acid to butter of antimony.

Bezoardicum saturni. A preparation of antimony and lead.

Bezo'ardicus lapis. See *Bezoar.*

Bezoardicus Pulvis. The powder of the oriental bezoar.

Bezoarticum minerale. A calx of antimony.

Bezoas. An absolete chemical epithet.

BI. (From *bis*, twice.) In composition signifies twice or double, and is frequently attached to other words in anatomy, chemistry, and botany; as *biceps*, having two heads; *bicuspides*, two points, or fangs; *bilocular*, with two cells; *bivalve*, with two valves, &c.

Biæon. Wine made from sun-raisins, fermented in sea water.

Bibine'lla. See *Pimpinella.*

BIBITO'RIUS. (*Bibitorius*, from *bibo*, to drink; because by drawing the eye inwards towards the nose, it causes those who drink to look into the cup.) See *Rectus internus oculi.*

BIBULUS. Bibulous; attracting moisture: *charta bibula*, blotting paper.

BICAPSULARIS. Having two capsules. *Pericarpium bicapsulare.* See *Capsula.*

BI'CEPS. (From *bis*, twice, and *caput*, a head.) Two heads. Applied to muscles from their having two distinct origins or heads.

Biceps brachii. See *Biceps flexor cubiti.*

Biceps cruris. See *Biceps flexor cruris.*

Biceps cubiti. See *Biceps flexor cubiti.*

Biceps externus. See *Triceps extensor cubiti.*

Biceps flexor cruris. *Biceps cruris* of Albinus. *Biceps* of Winslow, Douglas, and Cowper; and *Ischio-femoroperonien* of Dumas. A muscle of the leg, situated on the hind part of the thigh. It arises by two distinct heads; the first, called *longus*, arises in common with the semitendinosus, from the upper and posterior part of the tuberosity of the os ischium. The second, called *brevis*, arises from the linea aspera, a little below the termination of the glutæus maximus, by a fleshy acute beginning, which soon grows broader, as it descends to join with the first head, a little above the external condyle of the os femoris. It is inserted, by a strong tendon, into the upper part of the head of the fibula. Its use is to bend the leg. This muscle forms what is called the outer hamstring; and between it and the inner, the nervous popliteus, arteria and vena poplitea, are situated.

BICEPS FLEXOR CUBITI. *Biceps brachii* of Albinus. *Coraco-radialis, seu biceps* of Winslow. *Biceps internus* of Douglas. *Biceps internus humeri* of Cowper. *Scapulocoracoradial* of Dumas. A muscle of the fore-arm, situated on the fore-part of the *os humeri*. It arises by two heads. The first and outermost, called *longus*, begins tendinous from the upper edge of the glenoid cavity of the scapula, passes over the head of the os humeri within the joint, and in its descent without the joint, is inclosed in a groove near the head of the os humeri, by a membraneous ligament that proceeds from the capsular ligament and adjacent tendons. The second, or innermost head, called *brevis*, arises, tendinous and fleshy, from the coracoid process of the scapula, in common with the coracobrachialis muscle. A little below the middle of the fore-part of the os humeri, these heads unite. It is inserted by a strong roundish tendon into the tubercle on the upper end of the radius internally. Its use is to turn the hand supine, and to bend the fore-arm. At the bending of the elbow, where it begins to grow tendinous, it sends off an aponeurosis, which covers all the muscles on the inside of the fore-arm, and joins with another tendinous membrane, which is sent off from the triceps extensor cubiti, and covers all the muscles on the outside of the fore-arm, and a number of the fibres, from opposite sides, decussate each other. It serves to strengthen the muscles, by keeping them from swelling too much outwardly when in action, and a number of their fleshy fibres take their origin from it.

BICEPS INTERNUS. See *Biceps flexor cubiti.*

BICHI'CHIÆ. An epithet of certain pectorals, or rather troches, described by Rhazes, which were made of liquorice, &c.

BI'CHOS. A Portuguese name for the worms that get under the toe of the people in the Indies, which are destroyed by the oil of cashew nut.

BICI. The Indian name of an intoxicating liquor, made from Turkey wheat in South America. See *Wheat, Turkey.*

BI'CORNIS. (From *bis*, twice, and *cornu*, a horn.) 1. An epithet sometimes applied to the os hyoides, which has two processes, or horns.

2. In former times, to muscles that had two terminations.

3. A name given to those plants, the antheræ of which have the appearance of two horns.

BICORNES PLANTÆ. The name of an order of plants in the natural method of Linnæus and Gerard.

BICUSPIDATUS. Having two points. See *Bicuspis.*

BICUSPIS. (From *bis*, twice, and *cuspis*, a spear.) 1. The name of those teeth which have double points, or fangs. See *Teeth.*

2. Applied to leaves, which terminate by two points; *folia bicuspida* or *bicuspidata.*

BI'DENS. (From *bis*, twice, and *dens*, a tooth; so called from its being deeply serrated, or indented.) The name of a genus of plants in the Linnæan system. Class, *Syngenesia*; Order, *Polygamia æqualis.*

BIDENS TRIPARTITA. The systematic name of the hemp agrimony, formerly used as a bitter and aperient, but not in the practice of the present day.

BIDLOO, GODFREY, a celebrated anatomist born at Amsterdam, in 1649. After practising several years as a surgeon, he was appointed physician to William III., and in 1694, made professor of anatomy and surgery at Leyden. He published 105 very splendid, though rather inaccurate anatomical tables, with explanations; and several minor works. His nephew, *Nicholas*, was physician to the Czar Peter I.

BIENNIS. Biennial. A biennial plant is one, as the term imports, of two years, duration. Of this tribe there are numerous plants, which being raised one year from the seed, generally attain perfection the same year, or within about twelve months, shooting up stalks, producing flowers, and perfecting seeds in the following spring or summer, and soon after commonly perish.

BIFARIAM. In two parts.

BIFER. (From *bis*, twice, and *fero*, to bear.) A plant is so called, which bears twice in the year, in spring and autumn, as is common between the tropics.

BIFIDUS. Forked. Divided into two; as a bifid seed-vessel in *Adoxa moschatellina*, *petala bifida* in the *Silene nocturna* and *Alyssum incanum.*

BIFLORUS. Bearing two flowers; as *pedunculus biflorus.*

BIFORIUM. Applied to a leaf which points two ways.

BIFORUS. (From *bis*, twice, and *forus*, a door.) Two-doored or bivalved. A class of plants is so denominated in some natural arrangements, constituted by those which have a pericarp, or seed vessel, furnished with two valves.

BIFURCATE. (*Bifurcus*; from *bis*, twice, and *furca*, a fork.) A vessel, or nerve, stem, root, &c. is said to bifurcate when it divides into two branches; thus the bifurcation of the aorta, &c.

BIFURCATIO. Bifurcation.

BIFURCATUS. (From *bis*, twice, and *furca*, a fork.) Forked. See *Bifurcate* and *Dichotomus.*

BIGA'STER. (*Bigaster*: from *bis*, twice, and γαςηρ, a belly.) A name given to muscles which have two bellies.

BIGEMINATUS. (From *bis* and *gemini*, twins.) Twice paired. *Biconjugatus.* A leaf is so called when near the apex of the common petiole there is a single pair of secondary petioles, each of which support a pair of opposite leaflets; as in *Mimosa unguis cati.*

BIH'ERNIUS. (From *bis*, double, and *hernia*, a disease so called.) Having a double hernia or one on each side.

Bihydroguret of carbon. See *Carburetted hydrogen.*

BIJUGUS. A winged leaf is termed *folium bijugum*, which bears two pairs of leaflets.

BILABIATUS. Two-lipped. Often used in botany; as *pericarpium bilabiatum*; *corolla bilabeata*, &c.

BILACINIATUS. Applied to a leaf. *Folium bilaciniatum*; when cut into two segments.

BILA'DEN. A name of iron.

BILAMELLATUS. Composed of two lamina.

Bilberry bean. See *Arbutus uva ursi.*

BILDSTEIN. See *Figurestone.*

BILE. (*Bilis.* Nævius derives it from *bis*, twice, and *lis*, contention; as being supposed to be the cause of anger and dispute.) The gall. A bitter fluid, secreted in the glandular substance of the liver; in part flowing into the intestines, and in part regurgitating into the gall-bladder. The secretory organs of this fluid are the penicilli of the liver, which terminate in very minute canals, called biliary ducts. The biliary ducts pour their bile into the *ductus hepaticus*, which conveys it into the *ductus communis choledochus*, from whence it is in part carried into the duodenum. The other part of the bile regurgitates through the cystic duct into the gall-bladder: for hepatic bile, except during digestion, cannot flow into the duodenum, which contracts when empty; hence it necessarily regurgitates into the gall-bladder. The branches of the *vena portæ* contribute most to the secretion of bile; its peculiar blood, returning from the abdominal viscera, is supposed to be, in some respects, different from other venal blood, and to answer exactly to the nature of bile. It is not yet ascertained clearly whether the florid blood, in the hepatic artery, merely nourishes the liver, or whether, at the same time, it contributes a certain principle, necessary for the formation of bile. It has been supposed, by physiologists, that cystic bile was secreted by the arterial vessels of the gall-bladder; but the fallacy of this opinion is proved by making a ligature on the cystic duct of a living animal. From what has been said, it appears that there are, as it were, two kinds of bile in the human body:—

1. *Hepatic bile*, which flows from the liver into the duodenum: this is thin, of a faint yellow colour, inodorous, and very slightly bitter, otherwise the liver of animals would not be eatable.

2. *Cystic bile*, which regurgitates from the hepatic duct into the gall-bladder, and there, from stagnating, becomes thicker, the aqueous part being absorbed by lymphatic vessels, and more acrid from concentration. Healthy bile is of a yellow, green colour; of a plastic consistence, like thin oil, and when very much agitated, it froths like soap and water: its smell is fatuous, somewhat like musk, especially the putrefying or evaporatiug bile of animals: its taste is bitter.

The primary uses of this fluid, so important to the animal economy, are:

1. *To separate the chyle from the chyme:* thus chyle is never observed in the duodenum before the chyme has been mixed with the bile: and thus it is that oil is extricated from linen by the bile of animals.

2. By its *acridity* it excites the peristaltic motion of the intestines; hence the bowels are so inactive in people with jaundice.

3. It imparts a *yellow colour* to the excrements; thus we observe the white colour of the fæces in jaundice, in which disease the flow of bile into the duodenum is entirely prevented.

4. It prevents the *abundance of mucus and acidity* in the primæ viæ; hence acid, pituitous, and verminous saburra are common from deficient or inert bile.

The chemical analysis of bile has been principally illustrated by Mons. Thenard. "Ox bile is usually of a greenish-yellow colour, rarely a deep green. By its colour it changes the blue of turnsole and violet to a reddish-yellow. At once very bitter, and slightly sweet, its taste is scarcely supportable. Its smell, though feeble, is easy to recognise, and approaches somewhat to the nauseous odour of certain fatty matters, when they are heated. Its specific gravity varies very little. It is about 1.026 at 43° F. It is sometimes limpid, and at others disturbed with a yellow matter, from which it may be easily separated by water: its consistence varies from that of a thin mucilage, to viscidity. Cadet regarded it as a kind of soap. This opinion was first refuted by Thenard. According to this able chemist, 800 parts of ox bile, are composed of 700 water, 15 resinous matters, 69 picromel, about 4 of a yellow matter, 4 of soda, 2 phosphate of soda, 3.5 muriates of soda and potassa, 0.8 sulphate of soda, 1.2 phosphate of lime, and a trace of oxide of iron. When distilled to dryness, it leaves from 1-8th to 1-9th of solid matter, which, urged with a higher heat, is resolved into the usual igneous products of animal analysis; only with more oil and less carbonate of ammonia.

Exposed for some time in an open vessel, the bile gradually corrupts, and lets fall a small quantity of a yellowish matter; then its mucillage decomposes. Thus the putrefactive process is very inactive, and the odour it exhales is not insupportable, but in some cases has been thought to resemble that of musk. Water and alkohol combine in all proportions with bile. When a very little acid is poured into bile, it becomes slightly turbid, and reddens litmus; when more is added, the precipitate augments, particularly if sulphuric acid be employed. It is formed of a yellow animal matter, with very little resin. Potassa and soda increase the thinness and transparency of bile. Acetate of lead precipitates the yellow matter, and the sulphuric and phosphoric acids of the bile. The solution of the subacetate precipitates not only these bodies, but also the picromel and the muriatic acid, all combined with the oxyde of lead. The acetic acid remains in the liquid united to the soda. The greater number of fatty substances are capable of being dissolved by bile. This property, which made it be considered a soap, is owing to the soda, and to the triple compound of soda, resin, and picromel. Scourers sometimes prefer it to soap, for cleansing woollen. The bile of the calf, the dog, and the sheep, are similar to that of the ox. The bile of the sow contains no picromel. It is merely a soda-resinous soap. Human bile is peculiar. It varies in colour, sometimes being green, generally yellowish-brown, occasionally almost colourless. Its taste is not very bitter. In the gall-bladder it is seldom limpid, containing often, like that of the ox, a certain quantity of yellow matter in suspension. At times this is in such quantity, as to render the bile somewhat grumous. Filtered and boiled, it becomes very turbid, and diffuses the odour of white of egg. When evaporated to dryness, there results a brown extract, equal in weight to 1-11th of the bile. By calcination we obtain the same salts as from ox bile.

All the acids decompose human bile, and occasion an abundant precipitate of albumen and resin, which are easily separable by alcohol. One part of nitric acid, sp. grav. 1.210, saturates 100 of bile. On pouring into it a solution of sugar of lead, it is changed into a liquid of a light-yellow colour, in which no picromel can be found, and which contains only acetate of soda and some traces of animal matter. Human bile appears hence to be formed, by Thenard, in 1100 parts; of 1000 water; from 2 to 10 yellow insoluble matter; 42 albumen; 41 resin; 5.6 soda; and 45 phosphates of soda of lime, sulphate of soda, muriate of soda, and oxyde of iron. But by Berzelius, its constituents are in 1000 parts: 908.4 water; 80 picromel; 3 albumen; 4.1 soda; 0.1 phosphate of lime; 3.4 common salt; and 1 phosphate of soda, with some phosphate of lime."

BILGUER, John Ulrick, was born at Coire, in Swisserland. He practised surgery at

Berlin with such reputation, that he was appointed by the great Frederick, Surgeon-General to the Prussian army. It was then the general practice to amputate in bad compound fractures; and being struck with the small proportion of those who recovered after the operation, he was led to try more lenient methods; from which meeting with much better success, he published as a thesis, on graduating at Halle, in 1761, a pretty general condemnation of amputation. This work attracted much notice throughout Europe, and materially checked the unnecessary use of the knife. In his "Instructions for Hospital Surgeons," which appeared soon after, he insisted farther on the same subject; and where amputation was unavoidable, he advised leaving a portion of the integuments, which is now generally adopted.

BI′LIARY. (*Biliaris;* from *bilis*, the bile.) Of or belonging to the bile.

Biliary duct. *Ductus biliosus.* The very vascular *glandules*, which compose almost the whole substance of the liver, terminate in very small canals, called *biliary ducts*, which at length form one trunk, the *ductus hepaticus.* Their use is to convey the bile, secreted by the liver, into the hepatic duct; this uniting with a duct from the gall-bladder, forms one common canal, called the *ductus communis choledochus*, which conveys the bile into the intestinal canal.

Bili′mbi. (Indian.) See *Molus Indica.*

BI′LIOUS. (*Biliosus*, from *bilis*, bile.) A term very generally made use of, to express diseases which arise from too copious a secretion of bile: thus bilious colic, bilious diarrhœa, bilious fever, &c.

BI′LIS. See *Bile.*

Bilis atra. Black bile. The supposed cause among the ancients of melancholy.

Bilis cystica. *Bilis fellea.* Cystic bile. The bile when in the gall-bladder is so called to distinguish it from that which is found in the liver. See *Bile.*

Bilis hepatica. Hepatic bile. Bile that has not entered the gall-bladder. See *Bile.*

BI′LOBUS. (From *bis*, double, and *lobus*, the end of the ear.) Having two lobes, resembling the tips of ears; applied to a leaf, *folium bilobum*, when it is deeply divided into rounded segments, as the petals of the *Geranium pyrenaicum* and *striatum*, which are bilobed.

BILOCULARIS. (From *bis*, twice, and *loculus*, a little cell.) Two-celled; applied to a capsule which has two cells.

Biloculares. Is the name of a natural order of plants.

BIME′STRIS. (From *bis*, twice, and *mensis*, month.) Two months old.

BINATUS. *Binus.* Binate. A term applied to compound leaves, when consisting of a pair of leaflets only, on one foot-stalk as in the great everlasting pea and other species of *lathyrus.*

BINDWEED. See *Convolvulus sepium.*

BINERVIUS. Two-nerved. Having two ribs or nerves very apparent. Hence, *folium binervium.*

Binga′lle. See *Casumuniar.*

Bino′culus. (From *binus*, double, and *oculus*, the eye.) A bandage for securing the dressings on both eyes.

Bi′nsica. A disordered mind.—*Helmont.*

Binsica mors. The binsical, or that death which follows a disordered mind.

BINUS. (From *bis*, twice.) Two by two; by couplets; applied to leaves when there are only two upon a plant, *folia bina;* as in *Convallaria majalis*, &c.

Bioly′chnium. (From βιος, life, and λυχνιον, a lamp.) Vital heat: also the name of an officinal nostrum.

Bi′ote. (From βιος, life.) Life. Also light food.

BIOTHA′NATI. (From βια, violence, or βιος, life, and ϑανατος, death.) Those who die a violent death, or suddenly, as if there were no space between life and death.

BIPARTITUS. Bipartite. Deeply divided almost to the basis; as *calyx bipartitus; folium bipartitum; perianthium bipartitum;* and *petala bipartita.*

Bipemu′lla. See *Pimpinella.*

Bipene′lla. See *Pimpinella.*

BIPINATIFIDUS. Doubly pinnatifid; as in the long rough-headed poppy, *Papaver arzemone.* See *Pinnatifidus.*

BIPINNATIFIDUS. Doubly pinnatifid; applied to a leaf. See *Leaf.*

BIPINNATUS. Doubly pinnate. A compound leaf is so termed when the secondary petioles are arranged in pairs on the common petiole, and each secondary petiole is pinnate.

Bi′ra. Malt liquor or beer.

Bira′o. Stone parsley.

BIRCH. See *Betula.*

BIRDLIME. The best birdlime is made of the middle bark of the holly, boiled seven or eight hours in water, till it is soft and tender; then laid in heaps in pits in the ground and covered with stones, the water being previously drained from it; and in this state left for two or three weeks to ferment, till it is reduced to a kind of mucilage. This being taken from the pit is pounded in a mortar to a paste, washed in river water, and kneaded, till it is freed from extraneous matters. In this state it is left four or five days in earthen vessels, to ferment and purify itself, when it is fit for use.

It may likewise be obtained from the misletoe, the *Viburnum lantana*, young shoots of elder, and other vegetable substances.

It is sometimes adulterated with turpentine, oil, vinegar, and other matters.

Good birdlime is of a greenish colour, and sour flavour; gluey, stringy, and tenacious; and in smell resembling linseed oil. By exposure to the air it becomes dry and brittle, so that it may be powdered; but its viscidity is restored by wetting it. It reddens tincture of litmus. Exposed to a gentle heat it liquefies slightly, swells in bubbles, becomes grumous, emits a smell resembling that of animal oils, grows brown, but recovers its properties on cooling, if not heated too much. With a greater heat it burns, giving out a brisk flame and much smoke. The residuum contains sulphate and muriate of potassa, carbonate of lime and alumina, with a small portion of iron.

BIRDSTONGUE. A name given to the seeds of the *Flaxinus excelsior* of Linnæus.

Bi′rsen. (Hebrew for an aperture.) A deep ulcer, or imposthume in the breast.

BIRTHWORT. See *Aristolochia.*

Birthwort, climbing. See *Aristolochia clematitis.*

Birthwort, long-rooted. See *Aristolochia longa.*

Birthwort, snake-killing. See *Aristolochia anguicida.*

Birthwort, three-lobed. See *Aristolochia trilobata.*

BISCO′CTUS. (From *bis*, twice, and *coquo*, to boil.) Twice dressed. It is chiefly applied to bread much baked as biscuit.

Biscute′lla. Mustard.

Bise′rmas. A name formerly given to clary, or garden clary.

BISHOP'S WEED. See *Ammi.*

BISLI'NGUA. (From *bis*, twice, and *lingua*, a tongue; so called from its appearance of being double-tongued; that is, of having upon each leaf a less leaf.) The Alexandrian laurel.

Bisma'lva. (From *vismalva*, *quasi viscum malva*, from its superior viscidity.) The water, or marsh-mallow.

BI'SMUTH. (*Bismuthum*, from *Bismut*, Germ.) A metal which is found in the earth in very few different states, more generally native or in the metallic state. *Native bismuth* is met with in solid masses, and also in small particles dispersed in and frequently deposited on different stones, at Schreeberg in Saxony, Sweden, &c. Sometimes it is crystallised in four-sided tables, or indistinct cubes. It exists combined with oxygen in the *oxide of bismuth* (*bismut hochre*,) found in small particles, dispersed, of a bluish or yellowish-grey colour, needle-shaped and capillary; sometimes laminated, forming small cells. It is also, though more seldom, united to sulphur and iron in the form of a sulphuret in the *martial sulphuretted bismuth ore.* This ore has a yellowish-grey appearance, resembling somewhat the martial pyrites. And, it is sometimes combined with arsenic.

Bismuth is a metal of a yellowish or reddish-white colour, little subject to change in the air. It is somewhat harder than lead, and is scarcely, if at all malleable; being easily broken, and even reduced to powder, by the hammer. The internal face, or place of fracture, exhibits large shining plates disposed in a variety of positions; thin pieces are considerably sonorous. At a temperature of 480° Fahrenheit, it melts, and its surface becomes covered with a greenish-grey or brown oxide. A stronger heat ignites it, and causes it to burn with a small blue flame; at the same time that a yellowish oxide, known by the name of flowers of bismuth, is driven up. This oxide appears to rise in consequence of the combustion; for it is very fixed, and runs into a greenish glass when exposed to heat alone.

Bismuth urged by a strong heat in a closed vessel, sublimes entire, and crystallizes very distinctly when gradually cooled.

The sulphuric acid has a slight action upon bismuth, when it is concentrated and boiling. Sulphurous acid gas is exhaled, and part of the bismuth is converted into a white oxide. A small portion combines with the sulphuric acid, and affords a deliquescent salt in the form of small needles.

The nitric acid dissolves bismuth with the greatest rapidity and violence; at the same time that much heat is extricated, and a large quantity of nitric oxide escapes. The solution, when saturated, affords crystals as it cools; the salt detonates weakly, and leaves a yellow oxide behind, which effloresces in the air. Upon dissolving this salt in water, it renders that fluid of a milky white, and lets fall an oxide of the same colour.

The nitric solution of bismuth exhibits the same property when diluted with water, most of the metal falling down in the form of a white oxide, called magistery of bismuth. This precipitation of the nitric solution, by the addition of water, is the criterion by which bismuth is distinguished from most other metals. The magistery or oxide is a very white and subtle powder; when prepared by the addition of a large quantity of water, it is used as a paint for the complexion, and is thought gradually to impair the skin. The liberal use of any paint for the skin seems indeed likely to do this; but there is reason to suspect, from the resemblance between the general properties of lead and bismuth, that the oxide of this metal may be attended with effects similar to those which the oxides of lead are known to produce. If a small portion of muriatic acid be mixed with the nitric and the precipitated oxide be washed with but a small quantity of cold water, it will appear in minute scales of a pearly lustre, consisting the *pearl powder* of perfumers. These paints are liable to be turned black by sulphurated hydrogen gas.

The muriatic acid does not readily act upon bismuth.

When bismuth is exposed to chlorine gas it takes fire, and is converted into a chloride, which, formerly prepared by heating the metal with corrosive sublimate, was called butter of bismuth. The chloride is of a greyish-white colour, a granular texture, and is opaque. It is fixed at a red heat. When iodine and bismuth are heated together, they readily form an iodide of an orange-yellow colour insoluble in water, but easily dissolved in potassa ley.

Alkalis likewise precipitate its oxide; but not of so beautiful a white colour as that afforded by the affusion of pure water.

The gallic acid precipitates bismuth of a greenish-yellow, as ferroprussiate of potassa does of a yellowish colour.

There appears to be two sulphurets, the first a compound of 100 bismuth to 22.34 sulphur; the second of 100 to 46.5: the second is a bisnlphuret.

This metal unites with most metallic substances, and renders them in general more fusible. When calcined with the imperfect metals, its glass dissolves them, and produces the same effect as lead in cupellation; in which process it is even said to be preferable to lead.

Bismuth is used in the composition of pewter, in the fabrication of printers' types, and in various other metallic mixtures. With an equal weight of lead, it forms a brilliant white alloy, much harder than lead, and more malleable than bismuth, though not ductile; and if the proportion of lead be increased, it is rendered still more malleable. Eight parts of bismuth, five of lead, and three of tin, constitute the fusible metal, sometimes called Newton's, from its discoverer, which melts at the heat of boiling water, and may be fused over a candle in a piece of stiff paper without burning the paper. One part of bismuth, with five of lead, and three of tin, forms plumbers' solder. It forms the basis of a sympathetic ink. The oxide of bismuth precipitated by potassa from nitric acid, has been recommended in spasmodic disorders of the stomach, and given in doses of four grains, four times a-day. A writer in the Jena Journal says he has known the dose carried gradually to one scruple without injury.

Bismuth is easily separable, in the dry way, from its ores, on account of its great fusibility. It is usual, in the processes at large, to throw the bismuth ore into a fire of wood; beneath which a hole is made in the ground to receive the metal, and defend it from oxidation. The same process may be imitated in the small way, in the examination of the ores of this metal; nothing more being necessary, than to expose it to a moderate heat in a crucible, with a quantity of reducing flux; taking care, at the same time, to perform the operation as speedily as possible, that the bismuth may be neither oxydized nor volatilized.

BISMU'THUM. (From *bismut*, German.) See *Bismuth.*

BISSET, Charles, was born about the year 1716. After studying at Edinburgh, and practising some years as an Hospital-Surgeon in Jamaica, he entered the army; but soon after settled in Yorkshire, and in 1755, published a Treatise on the Scurvy. But his most celebrated work is an "Essay on the medical Constitution of Great Britain;" in 1762. He obtained three years after a diploma from St. Andrew's, and reached his 75th year.

BISTORT. See *Bistorta.*

BISTO'RTA. (From *bis*, twice, and *torqueo*, to bend; so called from the contortions of its roots.) Bistort. See *Polygonum bistorta.*

BISTOURY. (*Bistoire*, French.) Any small knife for surgical purposes.

BISTRE. A brown pigment, consisting of the finer parts of wood soot, separated from the grosser by washing. The soot of the beech is said to make the best.

BISULPHATE. A sulphate with an additional quantity of sulphuric acid.

BIT NOBEN. Salt of bitumen. A white saline substance has lately been imported from India by this name, which is not a natural production, but a Hindoo preparation of great antiquity. It is called in the country, *bit noben*, *padanoon*, and *soucherloon*, and popularly *khala mimuc*, or black salt. Mr. Henderson, of Bengal, conjectures it to be the *sal asphaltites* and *sal sodomenus* of Pliny and Galen. This salt is far more extensively used in Hindostan than any other medicine whatever. The Hindoos use it to improve their appetite and digestion. They consider it as a specific for obstructions of the liver and spleen; and it is in high estimation with them in paralytic disorders, particularly those that affect the organs of speech, cutaneous affections, worms, old rheumatisms, and indeed all chronic disorders of man and beast.

BITERNATUS. Twice-ternate. Applied to compound leaves, when the common footstalk supports three secondary petioles on its apex, and each of these support three leaflets; as in *Ægopodium.*

Bithi'nici emplastrum. A plaster for the spleen.

Bi'thinos. A Galenical plaster.

BITTER. *Amarus.*

BITTER APPLE. See *Cucumis Colocynthis.*

BITTERN. The mother water which remains after the crystillisation of common salt in sea water, or the water of salt springs. It abounds with sulphate and muriate of magnesia, to which its bitterness is owing.

BITTERSPAR. Rhombspar. A mineral of a greyish or yellowish colour, and somewhat pearly lustre, usually found embedded in serpentine, chlorite, or steatite, and found in the Tyrol, Salsburg, Dauphiny, Scotland, and the Isle of Man.

BITU'MEN. (*Πίτυμα, πίτυς*, pine; because it flows from the pine-tree, or, *quòd vi tumeat è terra*, from its bursting forth from the earth.) This term includes a considerable range of inflammable mineral substances, burning with flame in the open air. They are of different consistency, from a thin fluid to a solid; but the solids are for the most part liquefiable at a moderate heat. The fluid are,

1. Naphtha; a fine, white, thin, fragrant, colourless oil, which issues out of white, yellow, or black clays in Persia and Media. This is highly inflammable, and is decomposed by distillation. It dissolves resins, and the essential oils of thyme and lavender; but is not itself soluble either in alkohol or æther. It is the lightest of all the dense fluids, its specific gravity being 0.708. See *Naphtha.*

2. Petroleum, which is a yellow, reddish, brown, greenish, or blackish oil, found dropping from rocks, or issuing from the earth, in the duchy of Modena, and in various other parts of Europe, and Asia. This likewise is insoluble in alcohol, and seems to consist of naphtha, thickened by exposure to the atmosphere. It contains a portion of the succinic acid. See *Petroleum.*

3. Barbadoes tar, which is a viscid, brown, or black inflammable substance, insoluble in alkohol, and containing the succinic acid. This appears to be the mineral oil in its third state of alteration.

The solid are, 1. Asphaltum, mineral pitch, of which there are three varieties: the cohesive; the semi-compact, maltha; the compact, or asphaltum. These are smooth, more or less hard or brittle, inflammable substances, which melt easily, and burn without leaving any or but little ashes, if they be pure. They are slightly and partially acted on by alkohol and æther. See *Asphaltum.*

2. Mineral tallow, which is a white substance of the consistence of tallow, and as greasy, although more brittle. It was found in the sea on the coasts of Finland, in the year 1736; and is also met with in some rocky parts of Persia. It is near one-fifth lighter than tallow; burns with a blue flame, and a smell of grease, leaving a black viscid matter behind, which is more difficultly consumed.

3. Elastic bitumen, or mineral caoutchouc, of which there are two varieties. Beside these, there are other bituminous substances, as jet and amber, which approach the harder bitumens in their nature; and all the varieties of pit-coal, and the bituminous schistus, or shale, which contain more or less of bitumen in their composition.

Bitumen barbadense. See *Petroleum barbadense.*

Bitumen judaicum. *Asphaltus.* Jews' pitch. A solid light bituminous substance; of a dusky colour on the outside, and a deep shining black within; of very little taste, and scarcely any smell, unless heated; when it emits a strong pitchy one. It is said to be found plentifully in the earth in several parts of Egypt, and floating on the surface of the Dead Sea. It is now wholly expunged from the catalogue of officinals of this country; but was formerly esteemed as a discutient, sudorific, and emmenagogue.

Bitumen liquidum. See *Petroleum.*

BITUMINOUS. Of the nature of Bitumen.

Bituminous limestone. Found near Bristol, and in Galway, in Ireland. The Dalmatian is so charged with bitumen, that it may be cut like soap, and is used for building houses. When the walls are reared, fire is applied to them, and they burn white.

BIVALVIS. Two-valved. Applied to the valves of the absorbents in anatomy, and in botany to capsules.—*Capsula bivalvis.*

BIVASCULARIS. (From *bis*, twice, and *vasculum*, a little vessel.) Having two cells.

BIVE'NTER. (From *bis*, twice, and *venter*, a belly.) A muscle is so termed, which has two bellies.

Biventer cervicis. A muscle of the lower jaw.

Biventer maxillæ inferioris. See *Digastricus.*

BI'XA. The name of a genus of plants. Class, *Polyandria.* Order, *Monogynia.*

Bixa orleana. The systematic name for the plant affording the *terra orleana* or *annotto* of the shops and pharmacopœias. The substance so called is a ceraceous mass obtained from the pellicles of the seeds. In Jamaica and other warm climates, it is considered as a useful remedy in dysentery, possessing adstringent and stomachic qualities; but here it is only used to colour cheese and some other articles.

Bla'cciæ. The measles.—*Rhazes.*

BLA'CKBERRY. The fruit of the common brambles.—See *Rubus fruticosus*.

BLACK CHALK. A mineral of a bluish black colour, and slaty texture, which soils the fingers. It is found in primitive mountains, and occurs in Caernarvonshire, and the island of Isla.

BLACK JACK. Blende, or mock lead; an ore of zinc.

BLACK LEAD. See *Plumbago*.

BLACKMORE, Sir RICHARD, was born in Wiltshire about the year 1650. After studying at Oxford he took his degree in medicine at Padua, then settled in London, and met with considerable success, insomuch that he was appointed physician to William III. and retained the same office under Queen Anne. He then published several long and dull epic poems, which appear to have materially lessened his reputation; so that his opposition to the inoculation for small-pox had very little weight. He wrote also several medical tracts, which are little known at present.

BLACK WADD. One of the ores of manganese.

BLADDER. See *Urinary bladder*, and *Gall bladder*.

Bladder, inflamed. See *Cystitis*.

BLADE-BONE. See *Scapula*.

BLÆ'SITAS. (From *blæsus*.) A defect in speech called stammering.

BLÆ'SUS. (From βλαπτω, to injure.) A stammerer.

BLA'NCA. (*Blanc*, French.) A purging mixture; so called because it was supposed to evacuate the white phlegmatic humours. Also white lead.

BLA'NCA MULIERUM. White lead.

BLANCARD, STEPHEN, was born at Leyden, and graduated at Franeker, in 1678. He settled at Amsterdam, and published many anatomical and medical works; especially one on morbid anatomy, containing 200 cases and a "Lexicon Medicum," which passed through numerous editions.

BLA'SA. (Indian.) A tree, the fruit of which the Indians powder, and use to destroy worms.

BLASIUS, GERARD, son of a physician at Amsterdam, from whom he derived a great predilection for comparative anatomy. After graduating at Leyden about the year 1646, he returned to his native city, and acquired so much reputation, that he was made professor of medicine in 1660, and soon after physician to the hospital. Besides publishing new editions of several useful works, with notes comprehending subsequent improvements, he was author of various original ones, especially relating to comparitive and morbid anatomy. He claimed the discovery of the ductus salivaris, asserting he had pointed it out to Steno; to whom it has been commonly ascribed.

BLASTE'MA. (From βγαςανω, to germinate.) A bud or shoot. Hippocrates uses it to signify a cutaneous pimple like a bud.

BLA'STUM MOSYLITUM. Cassia bark kept with the wood.

BLA'TTA. (From βλαττω, to hurt.) A sort of beetle, or bookworm; so called from its injuring books and clothes; the kermes insect.

BLATTA'RIA LUTEA. (From *blatta*; so called, because, according to Pliny, it engenders the blatta.) The *Verbascum blattaria*, or herb yellow mothmullein.

BLEACHING. The chemical art by which the various articles used for clothing are deprived of their natural dark colour, and rendered white.

Bleaching Powder. The chloride of lime.

BLE'CHON. (From βληχαομαι, to bleat; so called according to Pliny, because if sheep taste it they bleat.) The herb, wild penny-royal. See *Mentha pulegium*.

BLEEDING. See *Blood-letting* and *Hæmorrhage*.

BLE'MA. (From ϐαλλω, to inflict.) A wound.

BLE'NDE. A species of zinc ore, formed of zinc in combination with sulphur.

BLE'NNA. Βλεννα. *Blena*. Mucus, a thick excrementitious humour.

BLENNORRHA'GIA. (From βλεννα, mucus, and ῥεω, to flow.) The discharge of mucus, from the urethra.

BLENNORRHŒ'A. (From βλεννα, mucus, and ῥεω, to flow.) 1. A gleet; *Gorcorrhœa mucosa*. A discharge of mucus from the urethra, arising from weakness.

2. The name of a genus of diseases in Good's Nosology, embracing three species, *Blennorrhœa simplex*, *luodes*, and *chroniea*.

BLE'PHARA. (*Quasi* βλεπους φαρος, as being the cover and defence of the sight.) The eyelids.

BLEPHA'RIDES. (From βλεφαρον.) The hair upon the eyelids; also the part of the eyelids where the hair grows.

BLEPHAROPHTHA'LMIA. (From βλεφαρον, the eyelid, and οφθαλμια, a disease of the eye.) An inflammation of the eyelid.

BLEPHAROPTO'SIS. (From βλεφαρον, the eyelid, and πτωσις, from πιπτω, to fall.) A prolapse, or falling down of the upper eyelid, so as to cover the cornea. See *Ptosis*.

BLEPHARO'TIS. (From βλεφαρον, the eyelid.) An inflammation of the eyelids.

BLEPHARO'XYSIS. (From βλεφαρον, the eyelid, and ξεω, to scrape off.) 1. The cleansing of the eyelids.

2. Inflammation of the eyelids.

BLEPHAROXY'STON. (From βλεφαρον, the eyelid, and ξεω, to scrape off.) A brush for the eyes. An instrument for cleansing or scraping off foul substances from the eyelids.

BLESSED. *Benedictus*. Applied to remedies and plants from their supposed virtues. See *Benedictus*.

Blessed Thistle. See *Centaurea benedicta*.

BLESTRI'SMUS. (From βαλλω, to throw about.) Phrenitic restlessness.

BLE'TA. A word used by Paracelsus to signify white, and applied to urine when it is milky, and proceeds from a disease of the kidneys.

BLE'TI. (*Bletus*, from βαλλω, to strike.) Those seized with dyspnœa or suffocation.

BLISTER. *Vesicatorium*; *Epispasticum*. 1. The name of a topical application, *Emplastrum vesicatorium*, which when put on the skin raises the cuticle in the form of a vesicle, filled with a serous fluid. Various substances produce this effect on the skin; but the powder of the *cantharis*, or blistering fly, is what operates with most certainty and expedition, and is now invariably made use of for the purpose.

It is a principle sufficiently established with regard to the living system, that where a morbid action exists, it may often be removed by inducing an action of a different kind in the same or neighbouring part. On this principle is explained the utility of blisters in local inflammation and spasmodic action, and it regulates their application in pneumonia, gastritis, hepatitis, phrenitis, angina, rheumatism, colic, and spasmodic affections of the stomach; diseases in which they are employed with the most marked advantage. A similar principle exists with respect to pain; exciting one pain often relieves another. Hence blisters often give relief in toothache, and some other painful affections. Lastly, blisters, by their operation, communicate a stimulus to the whole system, and raise the vigour of the circulation. Hence, in part, their utility in fevers of the typhoid kind, though in such cases they are used with still more advantage to obviate or remove local inflammation.

When it is not wished to maintain a discharge from the blistered part, it is sufficient to make a puncture in the cuticle to let out the fluid; but when the case requires keeping up a secretion of pus, the surgeon must remove the whole of the detached cuticle with a pair of scissors, and dress the excoriated surface in a particular manner. Practitioners used formerly to mix powder of cantharydes with an ointment, and dress the part with this composition. But such a dressing not unfrequently occasioned very painful affections of the bladder, a scalding sensation in making of water, and very afflicting stranguries. The treatment of such complaints consists in removing every particle of the fly from the blistered part, making the patient drink abundantly of mucilaginous drinks, giving emulsions and some doses of camphor.

These objections to the employment of salves containing the lytta, for dressing blistered surfaces, led to the use of mezereon, euphorbium, and other irritating substances, which, when incorporated with ointment, form very proper compositions for keeping blisters open, which they do without the inconvenience of irritating the bladder, like the blistering fly. The favourite application, however, for keeping open blisters, is the savine cerate, which was brought into notice by Mr. Crowther in his book on white swellings. (See *Ceratum Sabinæ.*) On the use of the savine cerate, immediately after the cuticle raised by the blister is removed, says Mr. Crowther, it should be observed that experience has proved the advantage of using the application lowered by a half or two-thirds of the unguentum ceræ. An attention to this direction will produce less irritation and more discharge, than if the savine cerate were used in its full strength. Mr. Crowther says also, that he has found fomenting the part with flannel, wrung out of warm water, a more easy and preferable way of keeping the blistered surface clean, and fit for the impression of the ointment, than scraping the part, as has been directed by others. An occasional dressing of unguentum resinæ flavæ, he has found a very useful application for rendering the sore free from an appearance of slough, or rather dense lymph, which has sometimes been so firm in its texture as to be separated by the probe, with as much readiness as the cuticle is detached after blistering. As the discharge diminishes, the strength of the savine dressing should be proportionably increased. The ceratum sabinæ must be used in a stronger or weaker degree, in proportion to the excitement produced on the patient's skin.

2. The name of a vesicle on the skin, whether formed by a blistering application, or arising from any other cause.

BLISTER-FLY. See *Cantharis.*

BLI'TUM FŒTIDUM. See *Chenopodium vulvaria.*

BLONDEL, JAMES AUGUSTUS, was born in England, of a French family, and admitted licentiate of the College of Physicians about 1720. He chiefly distinguished himself by controverting, in a very able manner, the opinion then generally received, that marks could be imprinted on the fœtus by the imagination of the mother, and he has the merit of contributing very largely to the removal of this prejudice, which had prevailed for ages, and often produced much mischief.

BLOOD. *Sanguis.* A red homogeneous fluid, of a saltish taste, and somewhat urinous smell, and glutinous consistence, which circulates in the cavities of the heart, arteries, and veins. The quantity is estimated to be about twenty-eight pounds in an adult; of this, four parts are contained in the veins, and a fifth in the arteries. The colour of the blood is red; in the arteries it is of a florid hue, in the veins darker; except only the pulmonary vessels in which the colour is reversed. The blood is the most important fluid of our body. Some physicians and anatomists have considered it as alive, and have formed many ingenious hypotheses in support of its vitality. The temperature of this fluid is of considerable importance, and appears to depend upon the circulation and respiration. The blood of man, quadrupeds, and birds, is hotter than the medium they inhabit; hence they are termed animals of *warm blood;* whilst in fishes and reptiles, animals with *cold blood*, it is nearly the temperature of the medium they inhabit. The blood possesses remarkable physical properties. Its colour is of a dark red, it is less deep in certain cases, and perhaps even scarlet. Its odour is insipid, and *sui generis;* its taste is also peculiar; however, it is known to contain salts, and principally the muriate of soda. Its specific gravity is a little more than that of water. Haller found its *medium* as 1.0527 : 1.0000. Its capacity for caloric may be expressed by 934, that of arterial blood being 921. Its mean temperature is 31 degrees of Reaumur,=102 F.

Venous blood, being extracted from its proper vessels, and left to itself, in a short time forms a soft mass; this mass *separates spontaneously* into two parts, the one liquid, yellowish, transparent, called *serum:* the other soft, almost solid, of a deep brown red, entirely opaque: this is the *cruor*, or *clot.* This occupies the bottom of the vessel; the serum is placed above. Sometimes a thin layer forms at the top of the serum, which is soft and reddish, and to which has been very improperly given the name of *rind, buff*, or *crust* of the blood.

This *spontaneous separation* of the elements of the blood does not take place quickly, except when it is in repose. If it is agitated it remains liquid, and preserves its homogeneity much longer.

If the venous blood is placed in contact with the atmosphere, or with oxygen gas, it takes a vermilion red colour; with ammonia it becomes cherry red; with azote a deeper brown red, &c. In changing colour it absorbs a considerable quantity of these different gases; it exhales a considerable quantity of carbonic acid, when kept some time under a bell upon mercury.

The serum sometimes presents a whitish tint, as if milky, which has made it be supposed that it contained chyle: it appears to be a fatty matter which gives it this appearance.

The cruor, or clot of the blood is essentially formed of fibrin, and colouring matter.

The fibrin, separated from the colouring matter, is whitish, insipid and inodorous; heavier than water, without action upon vegetable colours, elastic when humid, it becomes brittle by being dried.

In distillation it gives out a great deal of carbonate of ammonia, and a vast quantity of carbon, the ashes of which contain much phospate of lime, a little phosphate of magnesia, carbonate of lime, and carbonate of soda. A hundred parts of fibrin are composed of,

Carbon	53.360
Oxygen	19.685
Hydrogon	7.021
Azote	19.934
Total	100.000

The colouring matter is soluble in water and in the serum of the blood. Examined with the microscope in solution with these liquids, it appears like most fluids of the animal economy, formed of small globules; dried and calcined in contact with the air, it melts and swells up, burns with flame, and yields a coal that is difficultly reduced to ashes.

It is of importance to remark, that in none of the parts of the blood are any gelatine or phosphate of iron found, as was at first supposed.

The respective relations in quantity of the serum to the coagulum, and those of the colouring matter to the fibrin, have not yet been carefully examined. It is to be presumed, as we shall see afterwards, that they are variable according to an infinity of circumstances.

The coagulation of the blood has been, by turns, attributed to refrigeration, to the contact of the air, to the state of repose, &c.; but J. Hunter and Hewson have demonstrated by experiments, that this phenomenon cannot be attributed to any of these causes. Hewson took fresh blood, and froze it, by exposing it to a low temperature. He afterwards thawed it: the blood appeared fluid at first, and shortly afterwards it coagulated as usual. An experiment of the same kind was made by J. Hunter, with a similar result. Thus, blood does not coagulate because it is cooled. It even appears that a temperature a little elevated is favourable to its coagulation. We also know by experience that the blood thickens when it is deprived of the contact of the air, and agitated; its coagulation is, however, generally favoured by repose and the contact of the air.

The elements of venous blood, such as we have noticed, are known by its analysis; but as all the matters absorbed from the intestinal canal, the serous membranes, the cellular tissue, &c., are immediately mixed with the venous blood, the composition of this liquid must vary in proportion to the matter absorbed. There will be found in it, in different circumstances, alcohol, æther, camphor, and salts, which it does not usually contain, &c., when these substances have been submitted to absorption in any part of the body.

When, by the aid of a strong lens, or a microscope, we observe the transparent parts of cold-blooded animals, we see in the blood-vessels an immense multitude of small, rounded molecules, which swim in the serum, and roll upon each other, whilst they flow through the arteries and the veins.

Similar observations have never been made upon the hot-blooded animals; the membranes and sides of the vessels being opaque. But as, in separating a drop of blood in water, rounded particles are often seen with the microscope, the existence of globules has been admitted for the blood of animals, and consequently for that of man.

Authors have related marvellous things of these globules. According to *Leuwenhoeck*, a thousand millions of those globules are not larger than a grain of sand. Haller, in speaking of cold-blooded animals, for he never could see those of hot-blooded animals, says, that they are to an inch as one inch is to five thousand. Some will have them of the same form and diameter in all animals: others, on the contrary, assert, that they have a particular form and size for each animal; some declare that they are spherical and solid, others that they are flattened, and pierced with a small hole in the centre; lastly, many believe that a globule is a species of small bladder, which contains a certain number of smaller globules.

Probably many errors of imagination, and optical illusions have slid into these different opinions. Dr. Magendie made a great number of microscopic experiments, in order to satisfy himself in this respect.

He has never seen in the blood of man diluted in water, any thing but particles of colouring matter, generally rounded, of different sizes, which, according as they are placed exactly or not in the focus of the microscope, appear sometimes spherical, sometimes flat, and, at other times, of the figure of a disc, pierced in the centre. All these appearances, he says, can be produced at pleasure, by varying the position of the particles relatively to the instrument, and he believes that bubbles of air have often been described and drawn for globules of blood; at least, nothing has more resemblance to certain figures of Hewson, than very small bubbles of air that are produced by slightly agitating the liquid submitted to the microscope.

The latest and most accurate chemical analysis of blood is as follows:

The specific gravity of the serum is about 1.029, while that of blood itself is 1.058. It changes syrup of violets to a green, from its containing free soda. At 156° serum coagulates, and resembles boiled white of egg. When this coagulated albumen is squeezed, a muddy fluid exudes, which has been called the serosity. According to Berzelius, 1000 parts of the serum of bullock's blood consist of 905 water, 79.99 albumen, 6.175 lactate of soda and extractive matter, 2.565 muriates of soda, and potassa, 1.52 soda and animal matter, and 4.75 loss. 1000 parts of serum of human blood consist, by the same chemist, of 905 water, 80 albumen, 6 muriates of potassa and soda, 4 lactate of soda with animal matter, and 4.1 of soda, and phosphate of soda with animal matter. There is no gelatin in serum.

The cruor has a specific gravity of about 1.245. By making a stream of water flow upon it till the water runs off colourless, it is separated into insoluble fibrin, and the soluble colouring matter. A little albumen has also been found in cruor. The proportions of the former two are, 64 colouring matter, and 36 fibrin in 100. To obtain the colouring matter pure, we mix the cruor with 4 parts of oil of vitriol previously diluted with 8 parts of water, and expose the mixture to a heat of about 160° for 5 or 6 hours. Filter the liquid while hot, and wash the residue with a few ounces of hot water. Evaporate the liquid to one-half, and add ammonia, till the acid be almost, but not entirely saturated. The colouring matter falls. Decant the supernatant liquid, filter and wash the residuum from the whole of the sulphate of ammonia. When it is well drained, remove it with a platina blade, and dry it in a capsule.

When solid, it appears of a black colour, but becomes wine-red by diffusion through water, in which, however, it is not soluble. It has neither taste nor smell. Alkohol and æther convert it into an unpleasant smelling kind of adipocire. It is soluble both in alkalies and acids. It approaches to fibrin in its constitution, and contains iron in a peculiar state, $\frac{1}{2}$ of a per cent. to the oxide of which may be extracted from it by calcination. The incinerated colouring matter weighs 1-80th of the whole; and these ashes consist of 50 oxide of iron, 7.5 subphosphate of iron, 6 phosphate of lime, with traces of magnesia, 20 pure lime; 16.5

carbonic acid and loss; or the two latter ingredients may be reckoned 32 carbonate of lime. Berzelius imagines that none of these bodies existed in the colouring matter, but only their bases, iron, phosphorus, calcium, carbon, &c. and that they were formed during the incineration. From the albumen of blood, the same proportion of ashes may be obtained, but no iron.

The importance of the blood is very considerable; it distends the cavities of the heart and blood-vessels, and prevents them from collapsing; it stimulates to contraction the cavities of the heart and vessels, by which means the circulation of the blood is performed; it generates within itself animal heat, which it propagates throughout the body; it nourishes the whole body; and, lastly, it is that source from which every secretion of the body is separated.

Blood, dragon's. See *Calamus rotang.*

Blood, spitting of. See *Hæmoptysis.*

Blood, vomiting of. See *Hæmatemesis.*

BLOOD-LETTING. Under this term is comprehended every artificial discharge of blood made with a view to cure or prevent a disease. Blood-letting is divided into *general* and *topical.* As examples of the former, *venæsection* and *arteriotomy* may be mentioned; and of the latter, the *application* of *leeches, cupping-glasses,* and *scarification.*

Blood-stone. See *Hæmatites,* and *Calcedony.*

Bloody flux. See *Dysenteria.*

BLOWPIPE. A very simple and useful instrument. That used by the anatomist is made of silver or brass, of the size of a common probe, or larger, to inflate vessels and other parts.

The chemical blow pipe is made of brass, is of about one-eighth of an inch diameter at one end, and the other tapering to a much less size, with a very small perforation for the wind to escape. The smaller one is beveled on one side.

BLUE PRUSSIAN. A combination of oxide of iron with the ferro-prussic acid.

BLUE SAXON. Made by digesting sulphuric acid and water, on powdered indigo.

BO'A. (From βους, an ox.) 1. A pustulous eruption like the small-pox, so called because it was cured, according to Pliny, by anointing it with hot ox-dung.

2. The name of a genus of serpents.

Boche'tum. *Decoctum secundarium.* A decoction of the woods prepared by a second boiling with fresh water.

Bo'chia. A subliming vessel.

Bo'chium. A swelling of the bronchial glands.

BODY. Whatever is capable of acting on our senses may be so denominated.

Bodies in *Natural Philosophy* are divided into *Ponderable* and *Imponderable.*

The first are those which may act upon several of our senses, and of which the existence is sufficiently established; of this kind are solids, fluids, and gases. The second are those which, in general, only act on one of our senses, the existence of which is by no means demonstrated, and which, perhaps, are only forces, or a modification of other bodies; such are caloric, light, the electric and magnetic fluids.

Ponderable bodies are endowed with common or general properties, and likewise with particular or secondary properties.

The general properties of bodies are,—extent, divisibility, impenetrability, mobility. A ponderable body, of whatever kind, always presents these four properties combined. Secondary properties are variously distributed among different bodies; as, hardness, porosity, elasticity, fluidity, &c. They constitute, by their combination with the general properties, the condition, or state of bodies. It is by gaining or losing some of these secondary properties that bodies change their state: for instance, water may appear under the form of ice, of a fluid, or of vapour, although it is always the same body. To present itself successively under these three forms, nothing more is necessary than the addition or abstraction of some of its secondary qualities.

Bodies are *simple* or *compound.*

Simple bodies are rarely met with in nature; they are almost always the product of art, and we even name them simple, only because art has not arrived at their decomposition. At present, the bodies regarded as simple are the following:—Oxygen, chlorine, iodine, fluorine, sulphur, hydrogen, boracium, carbon, phosphorus, azote, silicium, zirconium, aluminum, yttrium, glucinum, magnesium, calcium, strontium, barium, sodium, potassium, manganese, zinc, iron, tin, arsenic, molybdenum, chromium, tungsten, columbium, antimony, uranium, cerium, cobalt, titanium, bismuth, copper, tellurium, nickel, lead, mercury, osmium, silver, rhodium, palladium, gold, platinum, irridium, selenium, lithium, thorenum, wood, anium, cadmium.

Compound bodies occur every where; they form the mass of the globe, and that of all the beings which are seen on its surface. Certain bodies have a constant composition; that is to say, a composition that never is changed, at least from accidental circumstances: there are, on the contrary, bodies, the composition of which is changed at every instant.

This diversity of bodies is extremely important; it divides them naturally into two classes; bodies, the composition of which is constant, are named brute, or gross, inert, inorganic; but those the elements of which continually vary, are called living organized bodies.

Brute and organized bodies, differ from each other in respect, 1st, of form; 2d, of composition; 3d, of the laws which regulate their changes of state. The following table presents the differences which are best marked.

TABLE I.

DIFFERENCES BETWEEN INORGANIC AND LIVING BODIES.

1. *Form.*

Inorganic Bodies.	Living Bodies.
Angular Form.	Rounded Form.
Indeterminate Volume.	Determinate Volume.

2. *Composition.*

Inorganic Bodies.	Living Bodies.
Sometimes simple.	Never simple.
Seldom of more than 3 elements.	At least 4 elements, often 8 or 10.
Constant.	Variable.
Each part capable of existing independent of the others.	Each part more or less depending on the whole.
Capable of being decomposed and recomposed.	Capable of decomposition, but totally incapable of recomposition.

3. *Regulating Laws.*

Inorganic Bodies.	Entirely subject to attraction, and chemical affinity.	Living Bodies.	In part subject to attraction and chemical affinity. In part subject to a power unknown.

Living bodies are divided into two classes, one of which comprehends *Vegetables*, the other *Animals*.

TABLE II.

DIFFERENCES BETWEEN VEGETABLES AND ANIMALS.

Vegetables.	*Animals.*
Are fixed to the ground.	Move on the surface of the ground.
Have carbon for the principal base of their composition.	Have azot for the base of their composition.
Composed of four or five elements.	Often composed of eight or ten elements.
Find and assume in their vicinity their nourishment in a state of preparation.	Must act on their aliments, in order to render them fit for nourishment.
Are nourished by tubes opening externally.	Are nourished by an internal canal.

In Anatomy. The human body is divided by anatomists into the trunk and extremities: *i.e.* the head, and inferior and superior extremities, each of which have certain regions before any part is removed, by which the physician is enabled to direct the application of blisters and the like, and the situation of diseases is better described.

The head is distinguished into the hairy part and the face. The former has five regions, viz. the crown of the head or *vertex*, the fore-part of the head or *sinciput*, the hind-part or *occiput*, and the sides, *partes laterales capitis*. In the latter are distinguished, the region of the forehead, *frons;* temples, or *tempora;* the nose, or *nasus;* the eyes, or *oculi;* the mouth, or *os;* the cheeks, *buccæ;* the chin, or *mentum;* and the ears, or *aures*.

The trunk is distinguished into three principal parts, the neck, thorax, and abdomen. The neck is divided into the anterior region or *pars antica*, in which, in men, is an eminence called *pomum Adami;* the posterior region is called *nucha colli;* and the laterial regions, *partes laterales colli*.

The thorax is distinguished into the anterior region, in which are the *sternum* and *mammæ*, and at the inferior part of which is a pit or hollow called *scrobiculus cordis;* a posterior region, called *dorsum;* and the sides, or *latera thoracis*.

The abdomen is distinguished into an anterior region, properly the *abdomen;* a posterior region, called the loins, or *lumbi;* and lateral regions or flanks, called *latera abdominis*. The anterior region of the abdomen being very extensive, is subdivided into the *epigastric*, *hypochondriac*, *umbilical*, and *hypogastric* regions, which are described under their respective names. Immediately below the abdomen is the *mons veneris*, and at its sides the groins or *inguina*. The space between the organs of generation and the *anus*, or fundament, is called the *perinæum*.

The superior extremity is distinguished into the shoulder, *summitas humeri*, under which is the arm-pit, called *axilla* or *fovea axillaris;* the *brachium*, or arm; the *antibrachium*, or fore-arm, in which anteriorly is the bend of the arm, where the veins are generally opened, called *flexura antibrachii;* and posteriorly the elbow, called *angulus cubiti;* and the hand, in which are the *carpus* or wrist, the back or *dorsum manûs*, and the palm or *vola*.

The inferior extremity is divided into, 1. the region of the femur, in which is distinguished the *coxa* or *regio-ischiadica*, forming the outer and superior part; 2. the leg, in which are the knee or *genu*, the bend or *cavum poplitis*, and the calf or *sura;* 3. the foot, in which are the outer and inner ankle, or *malleolus exturnus* and *inturnus*, the back or *dorsum*, and the sole or *planta*.

BODY, COMBUSTIBLE. This term is given by chemists to all substances which, on account of their affinity for oxygen, are capable of burning.

BODY, GASEOUS. See *Gas*.

BODY, INFLAMMABLE. Chemists give this name to such bodies as burn with facility, and flame in an increased temperature, although, strictly speaking, all combustible bodies are inflammable bodies; such are the diamond, sulphur, bitumens, &c.

BODY, PHOSPHORESCENT. Bodies which produce light, though their temperature be not increased.

BO'E. (From *βοαω*, to exclaim.) Clamour, or moaning made by a sick person.

BOERHAAVE, HERMAN, was born at Voorhout, in Holland, December 31, 1668. His father, the pastor of the village, having nine children, educated them himself, and intending Herman for the church, was careful to ground him well in the learned languages; in which he made such rapid progress, that he was sent at 14 to Leyden. His father dying soon after in slender circumstances, he was fortunately supported by the burgomaster, Daniel Van Alphin; which Boerhaave ever remembered with gratitude. Among other studies, he was very partial to the mathematics, and improved so much as to be able to give private instructions in them, whereby he partly maintained himself. In 1690, he took his degree in philosophy, and in an inaugural thesis refuted the errors of the materialists. But he soon after turned his mind to the study of medicine, and attended dissections under Nuck; he greatly preferred Hippocrates among the ancient, and Sydenham among the modern physicians. He was made doctor of medicine at Harderwyck, in 1693; and in his dissertation on that occasion, insisted on the utility of observing the excretions in disease, especially the urine. He was then engaged in forming a new theory of medicine, by a judicious selection from all that had been before advanced; which was so well arranged, and so ably supported by him, that it became generally adopted, and prevailed throughout Europe for more than half a century. He gave also lectures on chemistry, with considerable reputation about the same period. The university of Leyden therefore appointed him, in 1701, professor of the theory of medicine; when he read an oration recommending the study of Hippocrates; and, as he declined some very advantageous offers from other parts, they afterwards augmented his salary. About this time he published another Latin oration, "On the Use of mechanical Reasoning in Medicine," which contributed to extend his fame. In 1709, he was appointed professor of botany, to which study he was ever after eminently attached. On that occasion, he produced another oration, maintaining that medicine would be best improved by observation, and by simplicity in prescriptions. His "Aphorisms" had appeared the year before, giving a brief account of the history and cure of diseases, a work universally admired; to which his pupil Van Swieten afterwards attached a very ample commentary. About the same time he published his "Institutes," treating of physiology. These two works, with successive improvements, passed through numerous editions, and were translated into every European, nay even into the Arabic language. In the year after, he printed a catalogue of the plants in the university garden. In 1714, he was made rector of the university, and at the end of the year for which he held the office, delivered a discourse "On attaining Certainty in Physics." About this period he was made professor of the practice of medicine, and in 1718, of chemistry also. His lectures on these subjects, and on botany, were delivered with such clearness and precision, that students thronged from every part to hear him; insomuch that Leyden could scarcely afford accommodations for them. He was also often consulted in difficult cases by physicians even in distant parts of the world. When appointed to the chemical chair he had published a short work on that subject; but some of his pupils having printed his lectures without authority, and very incorrectly, he was led to prepare them for the press in 1732. In his conversation, Boerhaave was generally familiar, in his demeanour grave, but disposed to occasional pleasantry; he was distinguished for piety, and on his moral character, his disciple Haller has passed a very high eulogium. Having acquired considerable wealth by his exertions, and being plain in his dress, as well as abstemious in his diet, he was by some accused of parsimony; but he spared no reasonable expense in procuring rare books, and foreign plants. Being of a vigorous constitution, and accustomed to much exercise abroad, he met with little interruption from illness; but in 1729, having become corpulent, and incapable of riding, his health began to suffer, and he was induced to resign his botanical and chemical appointments. In an oration then delivered, he recounted the chief events of his life, expressing himself grateful for the patronage which he had received from individuals; as well as to his own profession, for the little opposition shown to his opinions. It perhaps never happened, that so great a revolution in science was so readily brought about. The great reputation acquired by his extensive abilities, and the moderation of his character, particularly averse from contention, no doubt contributed materially to this result. In the year following, he was again made rector of the university of Leyden; and also elected a fellow of the Royal Society in London, having been previously admitted to the Royal Academy of Sciences in Paris. The remainder of his life was chiefly occupied in revising his own numerous productions, in publishing more correct editions of several esteemed authors, and in domestic recreations at his seat near Leyden, with his wife and daughter. Towards the end of 1737, he was attacked with symptoms of disease in the chest, which terminated his existence in the September following. His fellow-citizens erected an elegant monument to his memory.

BOETHE′MA. (From βοηθεω, to assist.) A remedy.

BOETHEMA′TICA. (From βοηθεω, to assist.) Favourable symptoms.

BOG-BEAN. See *Menyanthes trifoliata.*

BO′GIA GUMMI. Gamboge.

BOHEA. See *Thea.*

BOHN, JOHN, was born at Leipsic, in 1640; and after studying in many parts of Europe, graduated there, and was made successively professor of anatomy, and of therapeutics, public physician to the city, &c. Among numerous publications, he chiefly distinguished himself by his "Circulus anatomico physiologicus," and a treatise "De officio medici clinico et forensi," which latter particularly has great merit. He also well explained the judgment to be formed concerning wounds; and recommended purging with calomel in the beginning of small-pox. He died in 1718.

Bois de coissi. See *Quassia.*

Bolar earths. See *Bole.*

BOLE, (βωλος, a mass,) in chemistry, is a massive mineral, having a perfectly conchoidal fracture, a glimmering internal lustre, and a shining streak. Its colours are yellow-red, and brownish black, when it is called mountain soap. It is translucent or opaque. Soft, so as to be easily cut, and to yield to the nail. It adheres to the tongue, has a greasy feel, and falls to pieces in water. Sp. grav. 1.4 to 2. It may be polished. If it be immersed in water after it is dried, it falls asunder with a crackling noise. It occurs in wacke and basalt, in Silesia, Hessia, and Sienna in Italy, and also in the cliffs of the Giant's Causeway, Ireland. The black variety is found in the trap rocks of the isle of Sky. Several compounds were formerly used in medicine, particularly the Armenian and French; and in old pharmacopœias mention is made of red boles from Armenia, Lemnos, Strigonium, Portugal, Tuscany, and Livonia; yellow boles from Armenia, Tockay, Silesia, Bohemia, and Blois; white boles from Armenia, Lemnos, Nocera, Eretria, Lamos, Chio, Malta, Tuscany, and Goltberg. Several of these earths have been commonly made into little cakes or flat masses, and stamped with certain impressions; from which circumstance they received the name of *terræ sagillatæ*, or sealed earths.

BOLE, ARMENIAN. *Bolus Armeniæ.* Bole armenic. A pale but bright red-coloured earth, which is occasionally mixed with honey, and applied to children's mouths when afflicted with aphthæ. It forms, like all argillaceous earths, a a good tooth-powder, when mixed with some aromatic.

BOLETIC ACID. *Acidum boleticum.* An acid extracted from the expressed juice of the *Boletus pseudo-igniarius*, by M. Braconnot. The juice concentrated to a syrup by a very gentle heat, was acted on by strong alkohol. What remained was dissolved in water. When nitrate of lead was dropped into this solution, a white precipitate fell, which, after being well washed with water, was decomposed by a current of sulphuretted hydrogen gas. Two different acids were found in the liquid after filtration and evaporation. One in permanent crystals was boletic acid; the other was a small proportion of phosphoric acid. The former was purified by solution in alkohol, and subsequent evaporation.

It consists of irregular four-sided prisms, of a white colour, and permanent in the air. Its taste resembles cream of tartar; at the temperature of 68° it dissolves in 180 times its weight of water, and in 45 of alkohol. Vegetable blues are reddened by it. Red oxide of iron, and the oxides of silver and mercury, are precipitated by it from their solutions in nitric acid; but lime and barytes waters are not affected. It sublimes when heated, in white vapours, and is condensed in a white powder.—*Ann. de Chimie*, lxxx.

BOLE'TUS. (From βωλος, a mass, or βωλιτης, from its globular form.) The name of a genus of plants in the Linnæan system. Class, *Cryptogamia*; Order, *Fungi*. Boletus; Spunk.

Boletus cervi. The mushroom.

Boletus igniarius. The systematic name for the *agaricus* of the pharmacopœias. *Agaricus chirurgorum*; *Agaricus quercûs*; *Fungus igniarius*. Agaric of the oak; Touch-wood boletus; Female agaric. This fungus *Boletus:—acaulis pulvinatus lævis, poris tenuissimis* of Linnæus, has been much used by surgeons as an external styptic. Though still employed on the Continent, the surgeons in this country have not much confidence in it.

Boletus laricis. The systematic name for the officinal *agaricus albus*, which is met with on old larch trees, in different parts of Europe. Several preparations, as troches, an extract, and pills, are ordered to be made with it in foreign pharmacopœias, which are administered against phthisical complaints.

Boletus pini laricis. A species of agaric which grows on the larch.

Boletus suaveolens. The systematic name for the *fungus salicis* of the pharmacopœias. This species of fungus, *Boletus—acaulis superne lævis, salicibus*, of Linnæus, and the *Boletus albus* of Hudson, when fresh, has a suburinous smell, and at first an acid taste, followed by a bitter. It is seldom used at present, but was formerly given in phthisical complaints.

Boli'smus. A voracious appetite, according to Avicenna; but most probably meant for bulimus.

BOLOGNIAN STONE. A mixture of mucilage and powdered sulphate of barytes.

BO'LUS. (Βωλος, a bole or bolus.) Any medicine, rolled round, that is larger than an ordinary sized pea, and yet not too large to be swallowed.

Bolus armena. See *Bole, Armenian.*

Bolus armena alba. The white armenian bole.

Bolus armoniac. See *Bole, Armenian.*

Bolus blessensis. Bole of Blois. See *Bole.*

Bolus gallica. French Bole. A pale red-coloured bolar earth, variegated with irregular specks and veins of white and yellow. It is occasionally administered as an absorbent and antacid.

BOMBAX. See *Gossypium.*

BOMBIATE. *Bombias.* A salt formed by the union of the bombic acid with salifiable bases; thus, *bombiate of alumine*, &c.

BO'MBIC ACID. *Acidum bombicum.* Acid of the silk-worm. Silk-worms contain, especially when in the state of chrysalis, an acid liquor in a reservoir placed near the anus. It is obtained by expressing their juice in a cloth, and precipitating the mucilage by spirit of wine, and likewise by infusing the chrysalides in that liquor. This acid is very penetrating, of a yellow amber colour, but its nature and combinations are not yet well known.

BO'MBUS. Βομβος. 1. A resounding noise, or ringing of the ears.

2. A sonorous expulsion of flatus from the intestines.

3. Dr. Good gives this name to that variety of imaginary sound, *parapsis illusoria*, which is characterised by a dull, heavy, intermitting sound.

Bon arbor. A name given to the coffee-tree.

Bo'na. *Boona.* The phaseolus, or kidney-beans.

Bo'nduch indorum. See *Guilandina.*

BONE. *Os.* Bones are hard, dry, and insensible parts of the body, of a whitish colour, and composed of a spongy, compact, or recticular substance. They vary much in their appearances, some being long and hollow, others flat and compact, &c. The greater number of bones have several processes and cavities, which are distinguished from their figure, situation, use, &c. Thus processes extended from the end of a bone, if smooth and round, are called *heads*; and *condyles*, when flattened either above or laterally. That part which is beneath the head, and which exceeds the rest of the bone in smallness and levity, is called the neck. Rough, unequal processes are called *tuberosities*, or tubercles: but the longer and more acute, *spinous*, or *styloid* processes, from their resemblance to a thorn. Thin broad processes, with sharp extremities, are known by the name of *cristæ*, or *sharp edges*. Other processes are distinguished by their form, and called *alar*, or *pterygoid*; *mamillary*, or *mastoid*; *dentiform*, or *odontoid*, &c. Others, from their situation, are called *superior*, *inferior*, *exterior*, and *interior*. Some have their name from their direction; as *oblique*, *straight*, *transverse*, &c.; and some from their use, as *trochanters*, *rotators*, &c. *Furrows*, *depressions*, and *cavities*, are destined either for the reception of contiguous bones, to form an articulation with them, when they are called *articular cavities*, which are sometimes deeper, sometimes shallower; or they receive hard parts, but do not constitute a joint with them. Cavities serve also for the transmission and attachment of soft parts. Various names are given to them, according to the magnitude and figure of bones. If they be broad and large at the beginning, and not deep, but contracted at their ends, they are called *foveæ*, or *pits*. Furrows are open canals, extending longitudinally in the surface of bones. A hollow, circular tube, for the most part of the same diameter from beginning to end, and more or less crooked or straight, long or short, is named a *canal*. *Foramina* are the apertures of canals, or they are formed of the excavated margins of two bones, placed against each other. If such be the form of the margin of a bone, as if a portion were taken out of it, it is called a *notch*.

With respect to the formation of bone, there have been various opinions. Physiologists of the present day assert, that it is from a specific action of small arteries, by which ossific matter is separated from the blood, and deposited where it is required. The first thing observable in the embryo, where bone is to be formed, is a transparent *jelly*, which becomes gradually firmer, and is formed into *cartilage*. The cartilage gradually increases to a certain size, and when the process of ossification commences, vanishes as it advances. Cartilages, previous to the ossific action, are solid, and without any cavity; but when the ossific action of the arteries is about to commence, the absorbents become very active, and form a *small cavity* in which the bony matter is deposited; bone continues to be separated, and the absorbents model the mass into its required shape. The process of ossification is extremely rapid in utero; it advances slowly after birth, and is not completed in the human body till about the twentieth year. Ossification in the flat bones, as those of the skull, always begin from *central points*, and the radiated fibres meet the radii of other ossifying points, or the edges of the adjoining bone. In long bones, as those of the arm and leg, the clavical, metacarpal, and metatarsal bones, a *central ring* is formed in the body of the bone, the head and extremities being cartilage, in the centre of which ossification afterward begins. The central ring of the body shoots its bony fibres towards the head and extremities, which extend towards the body of the bone. The head and extremities at length come so close to the body as to be merely separated by a cartilage, which becomes gradually thinner until the twentieth year. Thick and round bones, as those of the tarsus, carpus, sternum, and patella, are, at first, all cartilage: ossification begins in the *centre* of each. When the bones are deprived of their soft parts, and are hung together in their natural situation, by means of wire, the whole is termed an *artificial* skeleton; but when they are kept together by means of their ligaments, it is called a *natural* skeleton.—The use of the bones are various, and are to be found in the account of each bone; it is, therefore, only necessary to observe, in this place, that they give shape to the body, contain and defend the vital viscera, and afford an attachment to all the muscles.

A Table of the Bones.

			Naviculare os	2
			Cuneiformia ossa	6
		Metatarsus		10
		Phalanges		28
Sesamoid bones of the thumb and great toe, occasionally found				8
			Total	248

Calcined human bones, according to Berzelius, are composed, in 100 parts, of 81.9 phosphate of lime, 3 fluate of lime, 10 lime, 1.1 phosphate of magnesia, 2 soda, and 2 carbonic acid. 100 parts of bones by calcination are reduced to 63. Fourcroy and Vauquelin found the following to be the composition of 100 parts of ox bones: 51 solid gelatin, 37.7 phosphate of lime, 10 carbonate of lime, and 1.3 phosphate of magnesia; but Berzelius gives the following as their constituents: 33.3 cartilage, 55.35 phosphate of lime, 3 fluate of lime, 3.85 carbonate of lime, 2.05 phosphate of magnesia, and 2.45 soda, with a little common salt.

About 1-30th of phosphate of magnesia was obtained from the calcined bones of fowls, by Fourcroy and Vauquelin. When the enamel of teeth rasped down, is dissolved in muriatic acid, it leaves no albumen, like the other bones. Fourcroy and Vauquelin state its components to be, 27.1 gelatin and water, 72.9 phosphate of lime. Messrs. Hatchett and Pepys rate its composition at 78 phosphate of lime, 6 carbonate of lime, and 16 water and loss. Berzelius, on the other hand, found only 2 per cent. of combustible matter in teeth. The teeth of adults, by Mr. Pepys, consist of 64 phosphate of lime, 6 carbonate of lime, 20 cartilage, and 10 water or loss. The fossil bones from Gibraltar, are composed of phosphate of lime and carbonate, like burnt bones. Much difference of opinion exists with regard to the existence of fluoric acid in the teeth of animals, some of the most eminent chemists taking opposite sides of the question. It appears that bones buried for many centuries still retain their albumen, with very little diminution of its quantity.

Fourcroy and Vauquelin discovered phosphate of magnesia in all the bones they examined, except human bones. The bones of the horse and sheep afford about 1-36th of phosphate of magnesia; those of fish nearly the same quantity as those of the ox. They account for this by observing, that phosphate of magnesia is found in the urine of man, but not in that of animals, though both equally take in a portion of magnesia with their food.

The experiments of Mr. Hatchett show, that the membranous or cartilaginous substance, which retains the earthy salts within its interstices, and appears to determine the shape of the bone, is albumen. Mr. Hatchett observes, that the enamel of tooth is analogous to the porcellaneous shells, while mother-of-pearl approaches in its nature to true bone.

A curious phenomenon with respect to bones is the circumstance of their acquiring a red tinge, when madder is given to animals with their food. The bones of young pigeons will thus be tinged of a rose colour in twenty-four hours, and of a deep scarlet in three days; but the bones of adult animals will be a fortnight in acquiring a rose colour. The bones most remote from the heart are the longest in acquiring this tinge. Mr. Gibson informs us, that extract of logwood too, in considerable quantity, will tinge the bones of young pigeons purple. On desisting from the use of this food, however, the colouring matter is again taken up into the circulation, and carried off, the bones regaining their natural hue in a short time. It was said by Du Hamel, that the bones would become coloured and colourless in concentric layers, if an animal were fed alternately one week with madder, and one week without; and hence he inferred, that the bones were formed in the same manner as the woody parts of trees. But he was mistaken in the fact; and indeed had it been true, with the inference he naturally draws from it, the bones of animals must have been out of all proportion larger than they are at present.

Bones are of extensive use in the arts. In their natural state, or dyed of various colours, they are made into handles of knives and forks, and numerous articles of turnery. We have already noticed the manufacture of volatile alkali from bones, the coal of which forms bone-black; or, if they be afterwards calcined to whiteness in the open air, they constitute the bone ashes of which cupels are made, and which, finely levigated, are used for cleaning articles of paste, and some other trinkets, by the name of burnt hartshorn. The shavings of hartshorn, which is a species of bone, afford an elegant jelly; and the shavings of other bones, of which those of the calf are the best, are often employed in their stead.

On this principle, Mr. Proust has recommended an economical use of bones, particularly with a view to improve the subsistence of the soldier. He first chops them into small pieces, throws them into a kettle of boiling water, and lets them boil about a quarter of an hour. When this has stood till it is cold, a quantity of fat, excellent for culinary purposes when fresh, and at any time fit for making candles, may be taken off the liquor. This, in some instances, amounted to an eighth, and in others even to a fourth, of the weight of the bones. After this the bones may be ground, and boiled in eight or ten times their weight of water, of which that already used may form a part, till about half is wasted, when a very nutritious jelly will be obtained. The boiler should not be of copper, as this metal is easily dissolved by the jelly; and the cover should fit very tight, so that the heat may be greater than that of boiling water, but not equal to that of Papin's digester, which would give it an empyreuma. The bones of meat that have been boiled are nearly as productive as fresh bones; but Dr. Young found those of meat that had been roasted afforded no jelly, at least by simmering, or gentle boiling.

Bones, growth of. See *Osteogeny.*

BONEBINDER. See *Osteocolla.*

BONET, THEOPHILUS, was born at Geneva in 1620, and graduated at Bologna. He had considerable practice, and was extremely zealous in the pursuit of morbid anatomy, as well as in extracting valuable observations from authors. His hearing becoming impaired, he devoted the latter part of his life to the arrangement of the materials which he had prepared. His principal work, entitled "Sepulchretum," published 1679, was highly approved: and laid the foundation of Morgagni's excellent treatise, "De Sedibus et Causis Morborum." Another publication of his, "Mercurius compilatitius," is an index of medical literature to the time of its appearance, 1682. His death occurred seven years after.

BONONIE'NSIS LAPIS. The Bononianstone. Called also *phosphorus bononiensis, phosphorus kircheri*, the light carrier, or Bononian phosphorus. As a medicine the stone is caustic and emetic.

BONTIUS, JAMES, was born at Leyden, where he studied medicine, and then went to practice in India. After his return, he wrote several valuable works on the diseases and practice of that country, as well as on its natural productions, animal and vegetable. The most esteemed is entitled "De Medicina Indorum," and appeared in 1642.

BO'NUS. Good. A term applied to plants, and remedies from their supposed efficacy.

BONUS HENRICUS. (*Henricus;* so called, because its virtues were detected by some one whose name was Henry.) See *Chenopodium bonus Henricus.*

BONY. *Osseus.* Of, or belonging to, or resembling bone.

BORACIC ACID. *Acidum boracicum.* Sedative salt of Homberg. Acid of Borax. Boracine acid. "The salt composed of this acid and soda, had long been used both in medicine and the arts under the name of borax, when Homberg first obtained the acid separate in 1702, by distilling a mixture of borax and sulphate of iron. He supposed, however, that it was a product of the latter, and gave it the name of *volatile narcotic salt of vitriol*, or *sedative salt.* Lemery the younger soon after discovered that it could be obtained from borax equally by means of the nitric or muriatic acid; Geoffroy detected soda in borax: and at length Baron proved by a number of experiments, that borax is a compound of soda and a peculiar acid. Cadet has disputed this; but he has merely shown, that the borax of the shops is frequently contaminated with copper; and Struve and Exchaquet have endeavoured to prove that the boracic and phosphoric acids are the same; yet their experiments only show, that they resemble each other in certain respects, not in all.

To procure the acid, dissolve borax in hot water, and filter the solution, then add sulphuric acid by little and little, till the liquid has a sensibly acid taste. Lay it aside to cool, and a great number of small shining laminated crystals will form. These are the boracic acid. They are to be washed with cold water, and drained upon brown paper.

Boracic acid thus procured is in the form of thin irregular hexagonal scales, of a silvery whiteness, having some resemblance to spermaceti, and the same kind of greasy feel. It has a sourish taste at first, then makes a bitterish cooling impression, and at last leaves an agreeable sweetness. Pressed between the teeth, it is not brittle but ductile. It has no smell; but, when sulphuric acid is poured on it a transient odour of musk is produced. Its specific gravity in the form of scales is 1.479; after it has been fused, 1.803. It is not altered by light. Exposed to the fire it swells up, from losing its water of crystallisation, and in this state is called calcined boracic acid. It melts a little before it is red hot, without perceptibly losing any water, but it does not flow freely till it is red, and then less than the borate of soda. After this fusion it is a hard transparent glass, becoming a little opaque on exposure to the air, without abstracting moisture from it, and unaltered in its properties, for on being dissolved in boiling water it crystallises as before. This glass is used in the composition of false gems.

Boiling water scarcely dissolves one-fiftieth part, and cold water much less. When this solution is distilled in close vessels, part of the acid rises with the water, and crystallises in the receiver. It is more soluble in alkohol, and alkohol containing it burns with a green flame, as does paper dipped in a solution of boracic acid.

Neither oxygen gas, nor the simple combustibles, nor the common metals, produce any change upon boracic acid, as far as is at present known. If mixed with finely powdered charcoal, it is nevertheless capable of vitrification; and with soot it melts into a black bitumen-like mass, which however is soluble in water, and cannot easily be burned to ashes, but sublimes in part. With the assistance of a distilling heat it dissolves in oils, especially mineral oils; and with these it yields fluid and solid products, which impart a green colour to spirit of wine. When rubbed with phosphorus it does not prevent its inflammation, but an earthy yellow matter is left behind. It is hardly capable of oxyding or dissolving any of the metals, except iron and zinc, and perhaps copper; but it combines with most of the metallic oxydes, as it does with the alkalies, and probably with all the earths, though the greater part of its combinations have hitherto been little examined. It is of great use in analyzing stones that contain a fixed alkali.

Crystallised boracid acid is a compound of 57 parts of acid and 43 of water. The honour of discovering the *radical* of *boracic acid*, is divided between Sir H. Davy and Gay Lussac and Thenard. The first, on applying his powerful voltaic battery to it, obtained a chocolate-coloured body in small quantity; but the two latter chemists, by acting on it with potassium in equal quantities, at a low red heat, formed *boron* and sub-borate of potass. For a small experiment, a glass tube will serve, but on a greater scale a copper tube is to be preferred. The potassium and boracic acid, perfectly dry, should be intimately mixed before exposing them to heat. On withdrawing the tube from the fire, allowing it to cool, and removing the cork which loosely closed its mouth, we then pour successive portions of water into it, till we detach or dissolve the whole matter. The water ought to be heated each time. The whole collected liquids are allowed to settle; when, after washing the precipitate till the liquid ceases to affect syrup of violets, we dry the boron in a capsule, and then put it into a phial out of contact of air. *Boron* is solid, tasteless, inodorous, and of a greenish-brown colour. Its specific gravity is somewhat greater than water. The prime equivalent of boracic acid has been inferred from the borate of ammonia, to be about 2.7 or 2.8; oxygen being 1.0; and it probably consists of 2.0 of oxygen + 0.8 of boron. But by Gay Lussac and Thenard, the proportions would be 2 of boron to 1 of oxygen.

The boracic acid has a more powerful attraction for lime than for any other of the bases, though it does not readily form *borate of lime*, by adding a solution of it to lime water, or decomposing by lime water the soluble alkaline borates. In either case an insiped white powder, nearly insoluble, which is the borate of lime, is, however, precipitated. The borate of barytes is likewise an insoluble, tasteless, white powder.

Bergman has observed, that magnesia, thrown by little and little into a solution of boracic acid, dissolved slowly, and the liquor on evaporation afforded granulated crystals, without any regular form: that these crystals were fusible in the fire without being decomposed; but that alkohol was sufficient to separate the boracic acid from the magnesia. If, however, some of the soluble magnesian salts be decomposed by alkaline borates in a state of solution, an insipid and insoluble borate of magnesia is thrown down. It is probable, therefore, that Bergman's salt was a borate of magnesia dissolved in an excess of boracic acid; which acid being taken up by the alkohol, the true borate of magnesia was precipitated in a white powder, and mistaken by him for magnesia.

One of the best known combinations of this acid is the native *magnesio-calcareous borate* of Kalkberg, near Lunenburg; the *wurfelstein* of the Germans, *cubic quartz* of various mineralogists, and boracite of Kirwan.

The *borate of potassa* is but little known, though it is said to be capable of supplying the place of that of soda in the arts; but more direct experiments are required to establish this effect. Like that, it is capable of existing in two states, neutral and with excess of base, but it is not so crystallisable, and assumes the form of parallelopipeds.

With *soda* the boracic acid forms two different salts. One, in which the alkali is more than triple the quantity necessary to saturate the acid, is of considerable use in the arts, and has long been known by the name of borax; under which its history and an account of its properties will be given. The *other* is a neutral salt, not changing the syrup of violets green like the borate with excess of base; differing from it in taste and solubility; crystallising neither so readily, nor in the same manner; not efflorescent like it; but like it, fusible into a glass, and capable of being employed for the same purposes. This salt may be formed by saturating the superabundant soda in borax with some other acid, and then separating the two salts; but it is obviously more eligible to saturate the excess of soda with an additional portion of the boracic acid itself.

Borate of ammonia forms in small rhomboidal crystals, easily decomposed by fire; or in scales, of a pungent urinous taste, which lose the crystalline form, and grow brown on exposure to the air.

It is very difficult to combine the boracic acid with *alumina*, at least in the direct way.

The boracic acid unites with *silex* by fusion, and forms with it a solid and permanent vitreous compound. This *borate of silex*, however, is neither sapid nor soluble, nor perceptibly alterable in the air; and cannot be formed without the assistance of a violent heat. In the same manner, triple compounds may be formed with silex and borates already saturated with other bases.

The boracic acid has been found in a disengaged state in several lakes of hot mineral waters near Monte Rotondo, Berchiaio, and Castellonuovo, in Tuscany, in the proportion of nearly nine grains in a hundred of water, by Hoeffer. Mascagni also found it adhering to schistus, on the borders of lakes, of an obscure white, yellow, or greenish colour, and crystallised in the form of needles. He has likewise found it in combination with ammonia.

BORACITE. Borate of magnesia. A crystallised mineral found in gypsum in the Kalberg, in Brunswick, and at Segeberg, in Holland. It is translucent, and of a shining greasy lustre, yellowish, greyish, or of a greenish-white colour. Vauquelin's Analysis gives 83.4 boracic acid, and 16.6 magnesia.

BO'RAGE. See *Borago.*

BORA'GO. (Formerly written *Corago;* from *cor*, the heart, and *ago*, to affect; because it was supposed to comfort the heart and spirits.) Borage. 1. The name of a genus of plants in the Linnæan system. Class, *Pentandria;* Order, *Monogynia.*

2. The pharmacopœial name of the officinal borage. See *Borago officinalis.*

Borago officinalis. The systematic name for the borage of the shops. *Corrago; Buglossum verum; Buglossum latifolium; Borago hortensis.* The leaves and flowers of this plant, *Borago—foliis omnibus alternis, calycibus patentibus* of Linnæus, are estemed in some countries as refrigerent and cordial. A syrup is prepared from the leaves in France, and used in pleurisies and inflammatory fevers. Their principal use in this island is in that grateful summer beverage, known by the name of cool tankard.

BO'RAS. See *Borate.*

Boras sodæ. Borate of soda. See *Borax.*

BO'RATE. *Boras.* A salt formed of boracic acid with an earthy, alkaline, or metallic base; as borate of soda, &c.

BO'RAX. (*Borak*, Arabian.) *Boras sodæ; Sub-boras sodæ.* The obsolete synonyms are *Chrysocolla; Capistrum auri; Ancinar; Borax-trion; Acestis anucar; Antincar; Tincal; Amphitane; Baurach; Nitrum factitium; Santerna,* and *Nitrum nativum.* "It does not appear that borax was known to the ancients, their chrysocolla being a very different substance, composed of the rust of copper, triturated with urine. The word borax occurs for the first time in the works of Geber.

Borax is found in the East, and likewise in South America.

The purification of borax by the Venetians and the Hollanders, was, for a long time, kept secret. Chaptal finds, after trying all the processes in the large way, that the simplest method consists in boiling the borax strongly, and for a long time, with water. This solution being filtered, affords by evaporation crystals, which are somewhat foul, but may be purified by repeating the operation.

Purified borax is white, transparent, rather greasy in its fracture, affecting the form of six-sided prisms, terminating in three-sided or six-sided pyramids. Its taste is styptic; it converts syrup of violets to a green; and when exposed to heat, it swells up, boils, loses its water of crystallisation, and becomes converted into a porous, white opaque mass, commonly called Calcined Borax. A stronger heat brings it into a state of quiet fusion; but the glassy substance thus afforded, which is transparent, and of a greenish yellow colour, is soluble in water, and effloresces in the air. It requires about eighteen times its weight of water to dissolve it at the temperature of sixty degrees of Fahrenheit; but water at the boiling heat dissolves three times this quantity. Its component parts, according to Kirwan are, boracic acid 34, soda 17, water 47."

Borax is rarely used internally in modern practice; and according to Murray, it does not appear to possess any activity, although it is supposed by some to be, in doses of half a drachm or two scruples, diuretic and emmenagogue. It is occasionally given in cardialgia as an antacid. Its solution is in common use as a cooling gargle, and to detach mucus, &c. from the mouth in putrid fever; and mixed with an equal quantity of sugar, it is used in the form of powder to remove the aphthous crust from the tongue in children. The salts formed by the union of the acid of borax with different bases are called borates.

BORBORY'GMUS. (From *βορβορυζω*, to make a noise.) The rumbling noise occasioned by flatus in the intestines. It frequently precedes hysterical affections. Dr. Good gives this name to that variety of his *Limosis flatus*, which is known by frequent rumbling of the bowels.

BORDEU, Theophilus de, a French physician, born in 1722. He graduated at Montpelier, and was soon after appointed inspector of the mineral waters at Bareges, and professor of anatomy. Subsequently he went to Paris, and was admitted to the faculty there in 1754. He died of apoplexy in his 55th year. His most esteemed work is on the cellular membrane; his distinctions of the pulse appear too nice for practical utility.

BORELLI, John Alphonsus, was born at Castelnuovo, in 1608. He first taught the mathematics in Sicily, then as professor at Pisa; and being soon after admitted to the celebrated academy del Cimento, he formed the design of explaining the functions of animal bodies on mathematical principles. For this purpose he applied himself diligently to dissection. His grand work, "De Motu Animalium," was published after his death, which happened in 1679, at the expense of Christina, queen of Sweden. The imposing appearance of his opinions gained them many converts at first, but they have been found very defective on maturer examination. He was author of many other publications on different subjects.

BORON. The combustible basis of boracic acid. See *Boracic acid.*

Boro'zail. An Ethiopian word for an epidemic disease, in appearance similar to the lues venerea.

Borra'go. See *Borago.*

Bo'rri. (Indian.) *Borri-borri. Boberri.* The Indian name for turmeric; also an ointment used there, in which the roots of turmeric are a chief ingredient.

Bo'sa. An Egyptian word for an inebriating mass, made of the meal of darnel, hempseed, and water.

Bo'smoros. (From *βοσκω*, to eat, and *μορος*, a part; because it is divided for food by the mill.) *Bosporas.* A species of meal.

Bota'le foramen. A name formerly applied to the foramen ovale of the heart.

BOTALLUS, Leonard, an eminent physician of Piedmont, flourished about the middle of the 16th century. He graduated at Padua; and attained considerable reputation, as well in surgery as in medicine; having the honour of attending two of the French kings, and the prince of Orange; the latter of whom he cured of a wound, in which the carotid artery had been injured. He published a treatise on gun-shot wounds, which long remained in high estimation. But that which chiefly gained him celebrity was a work on bleeding, general and local, which he recommended to be freely practised in a great variety of diseases, both acute and chronic. His opinions were adopted by many, and carried to an extravagant length, particularly in France; but more enlarged experience has tended greatly to lessen their prevalence.

Bota'nicon. (From *βοτανη*, an herb.) A plaster made of herbs, and described by Paulus Ægineta.

BOTANIST. *Botanicus.* One who understands the nature, history, and distinction of vegetables, on settled and certain principles, and can call every plant by a distinct, proper, and intelligible name.

BO'TANY. (*Botanica.* Βοτανικη; from *βοτανη*, an herb or grass, which is derived from *βοω*, or *βοσκω*, to feed, because grass is the chief food of the animals which are most useful to man.) That branch of natural history which relates to the vegetable kingdom, the second of the three grand assemblages into which all terrestrial objects are divided. It is a science not confined to the description and classification of plants, as has often been represented, but it comprehends many other important particulars. Its various objects may be conveniently arranged under the following general heads :—

1. The *terminology*, or description and nomenclature of the several parts of a plant, which are externally visible.

If all natural objects were simple in their form, it would not be easy to distinguish one from another, nor would it be possible to describe them so as to give a clear and precise idea of them. Hence a boundless variety, connected with general resemblances, is wisely and benevolently made their universal character. Every plant is composed of several parts, which differ in each other from their outward appearance, and which cannot fail to strike the most careless spectator. Many of them also are themselves compound, and are obviously capable of being divided into subordinate parts.

2. The *classification* or arrangement. A knowledge of the different parts of a plant must necessarily be gained before it is described. But amidst the numerous vegetable productions of even a single country, this of itself would avail but little. To give a peculiar name to every individual would be a labour which no invention or diligence can perform; and, if performed, would produce a burden which no memory can sustain. It is necessary, therefore, to pursue resemblances and differences through a number of gradations, and to found on them primary and subordinate divisions, either ascending from particulars to generals, or descending from generals to particulars. The former is the method in which science of every kind is slowly formed and extended; the latter that in which it is most easily taught. The number of stages through which these subdivisions should be carried is either not pointed out by nature, or enough of nature is not known to fix them with precision. They differ, therefore, in different systems; and, unfortunately, corresponding ones have not always been called by the same names.

3. The *synonyms* of plants, or the names by which they are distinguished in the writings of professed botanists and others, from the earliest times to the present.

4. The *sensible qualities* of plants or the different manner in which they severally affect the organs of sight, smell, taste, and touch.

5. The *anatomy of plants*, or description of the different visible parts of which their substance is composed.

6. The *physiology of plants*. A plant, like an animal, is a very compound, organised, living being, in which various operations, both chemical and mechanical, are continually carrying on, from its first production to its final dissolution. It springs from a seed fertilised by the pollen of its parent plant. It takes in foreign substances by its inhaling and absorbent vessels. It elaborates and assimilates to its own substance those parts of them that are nutritious, and throws off the rest. It secretes a variety of fluids by the means of glands, and other unknown organs. It gives that motion to its sap on which a continuance of its life depends.

7. The *purposes* to which different plants are *applied*, either as articles of food, ingredients in the composition of medicine, or materials and instruments in the useful and elegant arts; the soil and situation in which they are generally found, and which are most favourable to their growth, the time of year in which they open their flowers, and ripen their fruit, with many other incidental particulars, are properly within the province of the botanist. But as a botanist he is concerned with nothing more than the simple facts. The best methods of cultivating such as are raised in considerable quantities for the special use or amusement of man; the theory of their nutritious or medicinal properties; and the manner in which they are to be prepared, so as to effect the intended purposes; are the province either of the gardener, farmer, physician, chemist, or the artist.

8. The *history* of botany.

BOTANY BAY. An English settlement in New Holland, so called because it afforded the botanist numerous plants. A yellow resin goes by the name of Botany Bay gum, which exudes spontaneously from the trunk of the tree called *Acarois resinifera*, and also from the wounded bark. All the information that has been hitherto collected respecting the history of the yellow gum is the following :—The plant that produces it is low and small, with long grassy leaves; but the fructification of it shoots out in a singular manner from the centre of the leaves, on a single straight stem, to the height of twelve or fourteen feet. Of this stem, which is strong and light, like some of the reed class, the natives usually make their spears. The resin is generally dug up out of the soil under the tree, not collected from it, and may, perhaps, be that which Tasman calls "gum lac of the ground." Mr. Boles, surgeon of the Lady Penrhyn, gives a somewhat different account; and as this gentleman appears to have paid considerable attention to the subject, his account may certainly be relied upon. After describing the tree in precisely the same manner as above, he observes, that at the top of the trunk of the tree, long grassy leaves grow in great abundance. The gum is found under these leaves in considerable quantities: it commonly exudes in round tears, or drops, from the size of a large pea to that of a marble, and sometimes much larger. These are, by the heat of the sun, frequently so much softened, that they fall on the ground, and in this soft state adhere to whatever they fall upon: hence the gum is frequently found mixed with dirt, wood, the bark of the tree, and various other substances; so that one lump has been seen composed of many small pure pieces of various sizes, united together, which weighed nearly half a hundred weight. It is produced in such abundance, that one man may collect thirty or forty pounds in the space of a few hours. The convicts have another method of collecting it: they dig round the tree, and break off pieces of the roots which always have some, and frequently considerable quantities of the gum in them. This gum appears nearly, but not entirely, the same as that which exudes from the trunk of the tree; the former is often mixed with a strong smelling resinous substance of a black nature, and is so interwoven in the wood itself, that it is with difficulty separated. The latter appears a pure unmixed resinous substance.

Several experiments have been made, principally with the view of determining what menstruum would dissolve the gum the most readily, and in the greatest quantity, from which it appears alkohol and æther dissolve the most.

The diseases in which this resin is administered are those of the primæ viæ, and principally such as arise from spasm, a debility, a loss of tone, or a diminished action in the muscular fibres of the stomach and bowels, such as loss of appetite, sickness, vomiting, flatulency, heart-burn, pains in the stomach, &c. when they were really idiopathic complaints, and not dependent upon any disease in the stomach, or affections of other parts of the body communicated to the stomach. In debilities and relaxations of the bowels, and the symptoms from thence arising, such as purging and flatulency, it has been found of good effect. In certain cases of diarrhœa, however, (and it seemed those in which an unusual degree of irritability prevailed,) it did not answer so well, unless given in small doses, and combined with opiates, when the patient seemed to gain greater advantage than when opiates only were had recourse to. In cases of amenorrhœa, depending on (what most of those cases do depend upon) a sluggishness, a debility, and flaccidity of the system, this medicine, when assisted by proper exercise and diet, has, by removing the symptoms of dyspepsia, and by restoring the tone and action of the muscular fibres, been found very serviceable. This medicine does not, in the dose of about half a drachm, appear to possess any remarkably sensible operation. It neither vomits, purges, nor binds the belly, nor does it materially increase the secretion of urine or perspiration. It has, indeed, sometimes been said to purge, and at others to occasion sweating; but they are not constant effects, and when they do occur, it generally depends on some accidental circumstance. It should seem to possess, in a very extensive degree, the property of allaying morbid irritability, and of restoring tone, strength, and action, to the debilitated and relaxed fibre. When the gum itself is given, it should always be the pure unmixed part; if given in the form of a draught, it should be mixed in water with mucilage of gum-arabic; if made into pills, a small portion of Castile soap may be employed; it was found the lixiv. sapon. dissolved it entirely. It is commonly, however, made into a tincture by mixing equal parts of the gum and rectified spirit; one drachm of this tincture (containing half a drachm of the pure gum) made into a draught with water and syrup, by the assistance of fifteen grains of gum-arabic in mucilage, forms an elegant medicine, and at the same time very palatable. It soon solidifies by the sun, into pieces of a yellow colour of various sizes. It pulverises easily without caking; nor does it adhere to the teeth when chewed. It has a slightly sweet astringent taste. It melts at a moderate heat. When kindled, it emits a white fragrant smoke. It is insoluble in water, but imparts to it the flavour of storax. Out of nine parts, six are soluble in water, and astringent to the taste; and two parts are woody fibre.

Bo′thor. (Arabian.) Tumours; pimples in the face: also the small-pox or measles.

Bo′thrion. (From βοθριον, a little pit.) *Botrium.* 1. The socket for the tooth.

2. An ulceration of the cornea.

Bo′tia. A name given to scrophula.

Bo′tin. A name for turpentine.

Bo′tium. *Boetum.* 1. A broncocele.

2. Indurated bronchial glands.

Botothi′num. The most evident symptom of disease.

Botri′tis. (From βοτρυς, a bunch of grapes.) *Botryites.* A sort of burnt cadmia, collected in the top of the furnace, and resembling a bunch of grapes.

BOTRYOLITE. A brittle and moderately hard mineral, which occurs in mamillary concretions of a pearly or greyish-white colour, composed of silica, boracic acid, lime, oxide of iron and water. It comes from Norway.

BO′TRYS. (Βοτρυς, a cluster of grapes: so called because its seeds hang down like a bunch of grapes.) The oak of Jerusalem.

Botrys mexicana. See *Chenopodium ambrosioides.*

Botrys vulgaris. See *Chenopodium botrys.*

Bo′tus. *Botia.* *Botus barbatus.* A cucurbit of the chemist.

Bouba′lios. See *Momordica Elaterium,* and *Pudendum muliebre.*

Bou′bon. See *Bubo.*

BOUGI′E. (French for wax candle.) *Candela cerea; Candela medicata; Catheteres* of Swediaur; *Cerei medicati* of Le Dran; *Cereolus chirurgorum.* A term applied by surgeons to a long, slender instrument, that is introduced through the urethra into the bladder. Bougies made of the elastic gum are preferable to those made of wax. The caustic bougie differs from the ordinary one in having a thin roll of caustic in its middle, which destroys the stricture, or any part it comes in contact with. Those made of catgut are very seldom used, but are deserving of the attention of the surgeon. Bougies are chiefly used to overcome strictures in the urethra, and the introduction of them requires a good deal of address and caution. They should not be kept in the urethra so long at one time as to excite much pain or irritation. Before their use is discontinued, they should, if practicable, be carried the length of the bladder, in order to ascertain the extent of the strictures, taking care that this be performed not at once, but in a gradual manner, and after repeated trials, for much injury might arise from any hasty or violent efforts to remove the resistance that may present itself. There are bougies also for the œsophagus and rectum.

BOU′LIMUS. (From βου, greatly, and λιμος, hunger; or from βουλομαι to desire.) A canine or voracious appetite.

BOURNONITE. An antimonial sulphuret of lead.

Bovey coal. Of a brownish-black colour and lamellar texture, formed of wood, penetrated with petroleum or bitumen, and found in England, France, Italy, &c.

Bovi′llæ. (From *bos,* an ox, because cattle were supposed subject to it.) The measles.

Bovi′na fames. The same as bulimia.

Bovi′sta. See *Lycoperdon.*

BOX-TREE. See *Buxus.*

BOYLE'S FUMING LIQUOR. The hydroguretted sulphuret of ammonia.

Brache′rium. (From *brachiale,* a bracelet.) A truss or bandage for hernia; a term used by the barbarous Latin writers.

BRACHIÆ′US. Brachial; belonging to the arm.

Brachiæus externus. See *Triceps extensor cubiti.*

Brachiæus internus. See *Brachialis internus.*

Brachiæus musculus. See *Brachialis internus.*

BRACHIAL. *Brachialis.* Of or belonging to the arm.

Bra′chial artery. *Arteria brachialis.* The brachial artery is the continuation of the axillary artery, which, as it passes behind the tendon of the pectoralis major, receives the name of *brachial.* It runs down on the inside of the arm, over the musculus coraco-brachialis, and anconæus internus, and, along the inner edge of the biceps, behind the vena basilica, giving out small branches as it goes along. Below the bend of the arm it divides into the cubitalis and radialis. Sometimes, though rarely, the *brachial artery* is divided from its origin into two large branches, which run down on the arm, and afterwards on the fore-arm, where they are called *cubitalis* and *radialis.*

BRACHIA′LE. The word means a bracelet; but the ancient anatomical writers apply this term to the carpus, the part on which the bracelet was worn.

BRACHIA′LIS. See *Brachial.*

BRACHIALIS EXTERNUS. See *Triceps extensor cubiti.*

BRACHIALIS INTERNUS. *Brachiæus* of Winslow. *Brachiæus internus* of Cowper; and *Humero-cubital* of Dumas. A muscle of the fore-arm, situated on the fore-part of the os humeri. It arises fleshy from the middle of the os humeri, at each side of the insertion of the deltoid muscle, covering all the inferior and fore-part of this bone, runs over the joint, and adheres firmly to the ligament; is inserted, by a strong short tendon, into the coronoid process of the ulna. Its use is to bend the fore-arm, and to prevent the capsular ligament of the joint from being pinched.

BRACHIATUS. Brachiate. Applied to branches, panicles, &c. spread in four directions, crossing each other alternately in pairs; a common mode of growth in the branches of shrubs that have opposite leaves, as the lilac, syringa, &c.

BRA′CHII OS. See *Humeri os.*

BRACHIO-CUBITAL LIGAMENT. *Ligamentum brachio-cubitale.* The expansion of the lateral ligament, which is fixed in the inner condyle of the os humeri, runs over the capsular, to which it closely adheres, and is inserted like radii on the side of the great sigmoid cavity of the ulna; it is covered on the inside by several tendons, which adhere closely to it, and seem to strengthen it very considerably.

BRACHIO-RADIAL LIGAMENT. *Ligamentum brachio-radiale.* The expansion of the lateral ligament, which runs over the external condyle of the os humeri, is inserted round the coronary ligament, from thence all the way down to the neck of the radius, and also in the neighbouring parts of the ulna. Through all this passage it covers the capsular ligament, and is covered by several tendons adhering closely to both.

BRA′CHIUM. (Βραχιον, the arm.) The arm, from the shoulder to the wrist.

BRACHIUM MOVENS QUARTUS. See *Latissimus dorsi.*

BRACHU′NA. According to Avicenna, a species of furor uterinus.

BRACHYCHRO′NIUS. (From *βραχυς*, short, and *χρονος*, time.) A disease which continues but a short time.

BRACHYPNŒ′A. (From *βραχυς*, short, and *ϖνεω*, to breathe.) Shortness and difficulty of breathing.

BRA′CHYS. (From *βραχυς*, short.) A muscle of the scapula.

BRA′CIUM. Copper. Verdigris.

BRACTEA. (*Bractea*, a thin leaf or plate of metal.) A floral leaf. One of the seven fulcra or props of plants, according to Linnæus. A bractea is a little leaf-like appendage to some flowers, lying under or interspersed in the flower, but generally different in colour from the true leaves of the plant.

1. It is *green* in some; as in *Ocymum basilicum majus.*

2. *Coloured* in others; as in *Salvia horminum*, &c.

3. In some it is *caducous*, falling off before the flowers.

4. In others it remains; as in *Tibia europæa.*

Coma bracteata is, when the flower-stem is terminated with a number of very large bracteæ, resembling a bush of hair.

BRACTEATÆ. (From *bractea*, here meaning a corolla.) The name of a class of Boerhaave's method of plants, consisting of herbaceous vegetables, which have petals, and the seeds of which are furnished with a single lobe or cotyledon.

BRACTEATUS. (From *bractea*, a floral leaf.) Having a floral leaf; as *pedunculus bracteatus.*

BRACTEIFORMIS. Resembling a bractea or floral leaf.

BRADYPE′PSIA. (From *βραδυς*, slow, and *ϖεπτω*, to concoct.) Weak digestion.

BRA′GGAT. A name formerly applied to a ptisan of honey and water.

BRAIN. See *Cerebrum.*

Brain, little. See *Cerebellum.*

BRAN. *Furfur.* The husks or shells of wheat, which remain in the boulting machine. It contains a portion of the farinaceous matter, and is said to have a laxative quality. Decoctions of bran, sweetened with sugar, are used by the common people, and sometimes with success, against coughs, hoarseness, &c.

BRA′NCA. (*Branca*, the Spanish for a foot, or branch.) A term applied to some herbs, which are supposed to resemble a particular foot; as *branca leonis*, lion's foot; *branca ursina*, bear's foot.

BRANCA LEONINA. See *Alchemilla.*

BRANCA LEONIS. See *Alchemilla.*

BRANCA URSINA. See *Acanthus* and *Heracleum.*

BRA′NCHÆ. (From *βρεχω*, to make moist.) *Branchi.* Swelled tonsils, or glandulous tumours, of the fauces, which secrete saliva.

BRA′NCHUS. (From *βρεχω*, to moisten.) A defluxion of humours from the fauces.

BRANDY. *Spiritus Gallicus.* A colourless, slightly opaque, and milky fluid, of a hot and penetrating taste, and a strong and agreeable smell, obtained by distilling from wine. It consists of water, ardent spirit, and a small portion of oil, which renders it milky at first, and, after a certain time, colours it yellow. It is the fluid from which rectified or ardent spirit is obtained. Its peculiar flavour depends on the nature of the volatile principles, or essential oil, which come over along with it in the distillation, and likewise, in some measure, upon the management of the fire, the wood of the cask in which it is kept, &c. It is said that our rectifiers imitate the flavour of brandy, by adding a small proportion of nitrous æther to the spirit of malt, or molasses. The utility of brandy is very considerable, but, from its pleasant taste and exhilarating property, it is too often taken to excess. It gives energy to the animal functions; it is a powerful tonic, cordial, and antispasmodic; and its utility with camphire, in gangrenous affections, is very great.

BRANKS. The name in Scotland, for the mumps. See *Cynanche parotidæa.*

BRANKURSINE. See *Acanthus.*

BRASI′LIA. Brazil wood.

BRASILIENSE LIGNUM. See *Hæmatoxylum campechianum.*

BRASILIENSIS RADIX. The ipecacuanha root is sometimes so called.

BRA′SIUM. (From *βρασσω*, to boil.) Malt, or germinated barley.

BRA′SMA. (From *βρασσω*, to boil.) The unripe black pepper. Fermentation.

BRA′SMOS. The same.

BRASS. *Æs.* A combination of copper and zinc.

BRASSADE′LLA. *Brassatella.* The *Ophioglossum*, or herb, adder's tongue.

BRA′SSICA. (Varno says, *quasi præsica*; from *præseco*, to cut off; because it is cut from the stalk for use; or from ϖρασια, a bed in a garden where they are cultivated, or from βρασσω, to devour, because it is eagerly eaten by cattle.) The name of a genus of plants in the Linnæan system. Class, *Tetradynamia*; Order, *Siliquosa*. Crambe. Cabbage. Colewort.

Brassica alba. The white cabbage.

Brassica apiana. Jagged or crimpled colewort.

Brassica canina. *Mercurialis sylvestris*. See *Mercurialis annua*.

Brassica capitata. Cabbage. There are several varieties of cabbage, all of which are generally hard of digestion, producing flatulencies, and afford very little nourishment. These inconveniences are not experienced by those whose stomachs are strong and accustomed to them. Few vegetables run into a state of putrefaction so quickly as cabbages; they ought, therefore, always to be used immediately after cutting. In Holland and Germany there is a method of preserving them by cutting them into pieces and sprinkling salt and some aromatic herbs among them; this mass is put into a tub, where it is pressed close, and left to ferment, when it is called *sour crout*, or *sauer kraut*. These, and all pickles of cabbage, are considered as wholesome and antiscorbutic, from the vinegar and spices they contain.

Brassica congylodes. Turnip cabbage.

Brassica cumana. Red colewort.

Brassica eruca. *Brassica erucastrum. Eruca sylvestris*. The systematic name for the plant which affords the semen erucæ. Garden rocket. Roman rocket. Rocket gentle. *Brassica—foliis lyartis, caule hirsuto siliquis glabris*, of Linnæus. The seeds of this plant, and of the wild rocket, have an acrid taste, and are eaten by the Italians in their pickles, &c. They are said to be good aperients and antiscorbutics, but are esteemed by the above-mentioned people for their supposed aphrodisiac qualities.

Brassica erucastrum. See *Brassica eruca*.

Brassica florida. The cauliflower.

Brassica gongylodes. The turnip cabbage.

Brassica lacuturria. *Brassica lacuturris*. The Savoy plant.

Brassica marina. See *Convolvulus soldanella*.

Brassica napus. The systematic name for the plant from which the *semen napi* is obtained. *Napus sylvestris. Bunias*. Wild navew, or rape. The seeds yield, upon expression, a large quantity of oil called rape oil, which is sometimes ordered in stimulating linaments.

Brassica oleracea. The systematic name for the *brassica capitata* of the shops. See *Brassica capitata*.

Brassica rapa. The systematic name for the plant whose root is called turnip. *Rapum. Rapus. Napus. Napus dulcis*. The turnip. Turnips are accounted a salubrious food, demulcent, detergent, somewhat laxative and diuretic, but liable, in weak stomachs, to produce flatulencies, and prove difficult of digestion. The liquor pressed out of them, after boiling, is sometimes taken medicinally in coughs and disorders of the breast. The seeds are occasionally taken as diuretics; they have no smell, but a mild acrid taste.

Brassica rubra. Red cabbage. A very excellent test both for acids and alkalies in which it is superior to litmus, being naturally blue, turning green with alkalies, and red with acids.

Brassica sabauda. The Savoy plant.

Brassica sativa. The common garden cabbage.

Brasside'llica ars. A way of curing wounds, mentioned by Paracelsus, by applying the herb *Brassidella* to them.

Bra'thu. Βραθυ. An old name for savine.

BRAZIL WOOD. See *Cæsalpina crista*.

BREAD. *Panis*. "Farinaceous vegetables are converted into meal by trituration, or grinding in a mill; and when the husk or bran has been separated by sifting or bolting, the powder is called flour. This is composed of a small quantity of mucilaginous saccharine matter, soluble in cold water; much starch, which is scarcely soluble in cold water, but combines with that fluid by heat; and an adhesive grey substance insoluble in water, alcohol, oil, or æther, and resembling an animal substance in many of its properties.

When flour is kneaded together with water, it forms a tough paste, containing these principles very little altered, and not easily digested by the stomach. The action of heat produces a considerable change in the gluten, and probably in the starch, rendering the compound more easy to masticate, as well as to digest. Hence the first approaches towards the making of bread consisted in parching the corn, either for immediate use as food, or previous to its trituration into meal; or else in baking the flour into unleavened bread, or boiling it into masses more or less consistent; of all which we have sufficient indications in the histories of the earlier nations, as well as in the various practices of the moderns. It appears likewise from the Scriptures, that the practice of making leavened bread is of very considerable antiquity; but the addition of yeast, or the vinous ferment, now so generally used, seems to be of modern date.

Unleavened bread in the form of small cakes, or buiscuit, is made for the use of shipping in large quantities; but most of the bread used on shore is made to undergo, previous to baking, a kind of fermentation, which appears to be of the same nature as the fermentation of saccharine substances; but is checked and modified by so many circumstances, as to render it not a little difficult to speak with certainty and precision respecting it.

When dough or paste is left to undergo a spontaneous decomposition in an open vessel, the various parts of the mass are differently affected, according to the humidity, the thickness or thinness of the part, the vicinity or remoteness of fire, and other circumstances less easily investigated. The saccharine part is disposed to become converted into alcohol, the mucilage has a tendency to become sour and mouldy, while the gluten in all probability verges toward the putrid state. An entire change in the chemical attractions of the several component parts must then take place in a progressive manner, not altogether the same in the internal and more humid parts as in the external parts, which not only become dry by simple evaporation, but are acted upon by the surrounding air. The outside may therefore become mouldy or putrid, while the inner part may be only advanced to an acid state. Occasional admixture of the mass would of course not only produce some change in the rapidity of this alteration, but likewise render it more uniform throughout the whole. The effect of this commencing fermentation is found to be, that the mass is rendered more digestible and light; by which last expression it is understood, that it is rendered much more porous by the disengagement of elastic fluid, that separates its parts from each other, and greatly increases its bulk. The operation of baking puts a stop to this process, by evaporating a great part of the moisture which is requisite to favour the chemical attraction, and probably also by still farther changing the nature of the component parts. It is then bread.

Bread made according to the preceding method will not possess the uniformity which is requisite, because some parts may be mouldy, while others are not yet sufficiently changed from the state of dough. The same means are used in this case as have been found effectual in promoting the uniform fermentation of large masses. This consists in the use of a leaven or ferment, which is a small portion of some matter of the same kind, but in a more advanced stage of the fermentation. After the leaven has been well incorporated by kneading into fresh dough, it not only brings on the fermentation with greater speed, but causes it to take place in the whole of the mass at the same time; and as soon as the dough has by this means acquired a due increase of bulk from the carbonic acid, which endeavours to escape, it is judged to be sufficiently fermented, and ready for the oven.

The fermentation by means of leaven or sour dough is thought to be of the acetous kind, because it is generally so managed, that the bread has a sour flavour and taste. But it has not been ascertained that this acidity proceeds from true vinegar. Bread raised by leaven is usually made of a mixture of wheat and rye, not very accurately cleared of the bran. It is distinguished by the name of rye-bread; and the mixture of these two kinds of grain is called bread-corn, or meslin, in many parts of the kingdom, where it is raised on one and the same piece of ground, and passes through all the processes of reaping, threshing, grinding, &c. in this mixed state.

Yeast or barm is used as the ferment for the finer kinds of bread. This is the mucilaginous froth which rises to the surface of beer in its first stage of fermentation. When it is mixed with dough, it produces a much more speedy and effectual fermentation than that obtained by leaven, and the bread is accordingly much lighter, and scarcely ever sour. The fermentation by yeast seems to be almost certainly of the vinous or spirituous kind.

Bread is much more uniformly miscible with water than dough; and on this circumstance its good qualities most probably do in a great measure depend.

A very great number of processes are used by cooks, confectioners, and others, to make cakes, puddings, and other kinds of bread, in which different qualities are required. Some cakes are rendered brittle, or as it is called *short*, by an admixture of sugar or of starch. Another kind of brittleness is given by the addition of butter or fat. White of egg, gum-water, isinglass, and other adhesive substances, are used, when it is intended that the effect of fermentation shall expand the dough into an exceedingly porous mass. Dr. Percival has recommended the addition of salep, or the nutritous powder of the orchis root. He says, that an ounce of salep, dissolved in a quart of water, and mixed with two pounds of flour, two ounces of yeast, and eighty grains of salt, produced a remarkably good loaf, weighing three pounds two ounces; while a loaf made of an equal quantity of the other ingredients, without the salep, weighed but two pounds twelve ounces. If the salep be in too large quantity, however, its peculiar taste will be distinguishable in the bread. The farina of potatoes, likewise, mixed with wheaten flour, makes very good bread. The reflecting chemist will receive considerable information on this subject from an attentive inspection of the receipts to be met with in treatises of cooking and confectionary.

Mr. Accum, in his late Treatise on Culinary Poisons, states, that the inferior kind of flour which the London bakers generally use for making loaves, requires the addition of alum to give them the white appearance of bread made from fine flour. The baker's flour is very often made of the worst kinds of damaged foreign wheat, and other cereal grains mixed with them in grinding the wheat into flour. In this capital, no fewer than six distinct kinds of wheaten flour are brought into the market. They are called fine flour, seconds, middlings, fine middlings, coarse middlings, and twenty-penny flour. Common garden beans and pease are also frequently ground up among the London bread flour.

'The smallest quantity of alum that can be employed with effect to produce a white, light, and porous bread from an inferior kind of flour, I have my own baker's authority to state, is from three to four ounces to a sack of flour weighing 240 pounds.'

'The following account of making a sack of five bushels of flour into bread, is taken from Dr. P. Markham's Considerations on the Ingredients used in the Adulteration of Flour and Bread, p. 21.

Five bushels flour,
Eight ounces of alum,
Four lbs. salt,
Half a gallon of yeast mixed with about
Three gallons of water.

'Another substance employed by fraudulent bakers is subcarbonate of ammonia. With this salt they realise the important consideration of producing light and porous bread from spoiled, or what is technically called *sour flour*. This salt, which becomes wholly converted into a gaseous substance during the operation of baking, causes the dough to swell up into air-bubbles, which carry before them the stiff dough, and thus it renders the dough porous; the salt itself is at the same time totally volatilized during the operation of baking.'—'Potatoes are likewise largely, and, perhaps, constantly used by fraudulent bakers, as a cheap ingredient to enhance their profit.'—'There are instances of convictions on record, of bakers having used gypsum, chalk, and pipe-clay, in the manufacture of bread.'

Mr. E. Davy, Prof. of Chemistry at the Cork Institution, has made experiments, showing that from twenty to forty grains of common carbonate of magnesia, well mixed with a pound of the worst *new seconds* flour, materially improved the quality of the bread baked with it.

The habitual and daily introduction of a portion of alum into the human stomach, however small, must be prejudicial to the exercise of its functions, and particularly in persons of a bilious and costive habit. And, besides, as the best sweet flour never stands in need of alum, the presence of this salt indicates an inferior and highly acescent food; which cannot fail to aggravate dyspepsia, and which may generate a calculous diathesis in the urinary organs. Every precaution of science and law ought, therefore, to be employed to detect and stop such deleterious adulterations. Bread may be analysed for alum by crumbling it down when somewhat stale in distilled water, squeezing the pasty mass through a piece of cloth, and then passing the liquid through a paper filter. A limpid infusion will thus be obtained. It is difficult to procure it clear if we use new bread or hot water. A dilute solution of muriate of barytes dropped into the filtered infusion, will indicate by a white cloud, more or less heavy, the presence and quantity of alum. I find that genuine bread gives no precipitate by this treatment. The earthy adulterations are easily discovered by incinerating the bread at a red heat in a shallow earthen vessel, and treating the residuary ashes with a little nitrate of ammonia. The earths themselves will then remain, characterised by their whiteness and insolubility.

The latest chemical treatise on the art of making bread, except the account given by Mr. Accum in his work on the *Adulterations of Food*, is the article Baking in the Supplement to the Encyclopædia Britannica.

Under *Process of Baking* we have the following statement: 'An ounce of alum is then dissolved over the fire in a tin pot, and the solution poured into a large tub, called by the bakers the *seasoning-tub*. Four pounds and a half of salt are likewise put into the tub, and a pailfull of hot water.' Note on this passage.—'In London, where the goodness of bread is estimated entirely by its whiteness, it is usual with those bakers who employ flour of an inferior quality, to add *as much* alum as common salt to the dough. Or, in other words, the quantity of salt added is diminished one-half, and the deficiency supplied by an equal weight of alum. This improves the look of the bread very much, rendering it much whiter and firmer.' "—*Ure's Chem. Dict.*

BREAD-FRUIT. The tree which affords this, grows in all the Ladrone Islands in the South Sea, in Otaheite, and now in the West Indies. The bread-fruit grows upon a tree the size of a middling oak. The fruit is about the size of a child's head, and the surface is reticulated, not much unlike the surface of a truffle. It is covered with a thin skin, and has a core about the size of a small knife. The eatable part is between the skin and the core: it is as white as snow, and somewhat of the consistence of new bread. It must be toasted before it is eaten, being first divided into three or four parts. Its taste is insipid, with a slight sweetness, nearly like that of wheaten bread and artichoke together. This fruit is the constant food of the inhabitants all the year, it being in season eight months.

Bread-nut. See *Brosimum alicastrum.*

BREAST. *Mamma.* The two globular projections, composed of common integuments, adipose substance, and lacteal glands and vessels, and adhering to the anterior and lateral regions of the thorax of females. On the middle of each breast is a projecting portion, termed the *papilla* or *nipple*, in which the excretory ducts of the glands terminate, and around which is a coloured orb, or disc, called the *aureola*. The use of the breasts is to suckle new-born infants.

BREAST-BONE. See *Sternum.*

BRECCIA. An Italian term, frequently used by our mineralogical writers to denote such compound stones as are composed of agglutinated fragments of considerable size. When the agglutinated parts are rounded the stone is called pudding-stone. Breccias are denominated according to the nature of their component parts. Thus we have calcareous breccias, or marbles; and siliceous breccias, which are still more minutely classed, according to their varieties.

BRE′GMA. (From ϐρεχω, to moisten; formerly so called, because, in infants, and sometimes even in adults, they are tender and moist.) An old name for the parietal bones.

RRE′VIS. Short. Applied to distinguish parts differing only in length, and to some parts the termination of which is not far from their origin; as *brevia vasa*, the branches of the splenic vein.

Brey′nia. (An American plant named in honour of Dr. Brennius.) A species of capparis.

BRIAR. See *Rosa.*

Bri′cumum. A name which the Gauls gave to the herb artemisia.

BRIMSTONE. See *Sulphur.*

BRISTLE. See *Seta.*

BRISTOL HOT-WELL. *Bristoliensis aqua.* A pure, thermal or warm, slightly acidulated mineral spring, situated about a mile below Bristol. The fresh water is inodorous, perfectly limpid and sparkling, and sends forth numerous air-bubbles when poured into a glass. It is very agreeable to the palate, but without having any very decided taste, at least none that can be distinguished by a common observer. Its specific gravity is only 1.00077, which approaches so near to that of distilled water, that this circumstance alone would show that it contained but a very small admixture of foreign ingredients. The temperature of these waters, taking the average of the most accurate observations, may be reckoned at 74 deg.; and this does not very sensibly vary during winter or summer. Bristol water contains both solid and gaseous matter, and the distinction between the two requires to be attended to, as it is owing to the very small quantity of solid matter that it deserves the character of a very fine natural spring; and to an excess in gaseous contents that it seems to be principally indebted for its medical properties, whatever they may be, independent of those of mere water, with an increase of temperature. From the different investigations of chemists, it appears that the principal component parts of the Hot-Well water, are a large proportion of carbonic acid gas, or fixed air, and a certain portion of magnesia and lime, in various combinations, with the muriatic, vitriolic, and carbonic acids. The general inference is, that it is considerably pure for a natural fountain, as it contains no other solid matter than is found in almost all common spring water, and in less quantity.

On account of these ingredients, especially the carbonic acid gas, the Hot-Well water is efficacious in promoting salutary discharges, in greensickness, as well as in the blind hæmorrhoids. It may be taken with advantage in obstructions, and weakness of the bowels, arising from habitual costiveness; and, from the purity of its aqueous part, it has justly been considered as a specific in diabetes, rendering the urinary organs more fitted to receive benefit from those medicines which are generally prescribed, and sometimes successful.

But the high reputation which this spring has acquired, is chiefly in the cure of pulmonary consumption. From the number of unsuccessful cases among those who frequent this place, many have denied any peculiar efficacy in this spring, superior to that of common water. It is not easy to determine how much may be owing to the favourable situation and mild temperate climate which Bristol enjoys; but it cannot be doubted that the Hot-Well water, though by no means a cure for consumption, alleviates some of the most harassing symptoms of this formidable disease. It is particularly efficacious in moderating the thirst, the dry burning heat of the hands and feet, the partial night sweats, and the symptoms that are peculiarly hectical; and thus, in the earlier stages of phthisis, it may materially contribute to a complete re-establishment of health; and even in the latter periods, mitigate the disease when the cure is doubtful, if not hopeless.

The sensible effects of this water, when drunk warm and fresh from the spring, are a gentle glow of the stomach, succeeded sometimes by a slight and transient degree of headache and giddiness. By a continued use, in most cases it is diuretic, keeps the skin moist and perspirable, and improves the appetite and health. Its effects on the bowels are variable. On the whole, a tendency to costiveness seems to be the more general consequence of a long course of this medicinal spring, and therefore the use of a mild aperient is requisite. These effects, however, are applicable only to invalids, for healthy persons, who taste the water at the fountain, seldom discover any thing in it but a degree of warmth, which distinguishes it from the common element.

The season for the Hot-Well is generally from the middle of May to October; but as the medicinal properties of the water continue the same throughout the year, the summer months are preferred merely on account of the concomitant benefits of air and exercise.

It should be mentioned, that another spring, nearly resembling the Hot-Well, has been discovered at Clifton, which is situated on the summit of the same hill, from the bottom of which the Hot-Well issues. The water of Sion-spring, as it is called, is one or two degrees colder than the Hot-Well; but in other respects it sufficiently resembles it to be employed for all similar purposes.

BRITANNICA HERBA. See *Rumex hydrolapathum*, and *Arctium lappa*.

BRITA'NNICUS. British. Applied to plants which grow in this country, and to some remedies.

BRITISH GUM. When starch is exposed to a temperature between 600° and 700° it swells, and exhales a peculiar smell: it becomes of a brown colour, and in that state is employed by calico-printers. It is soluble in cold water, and does not form a blue compound with iodine. Vauquelin found it to differ from gum in affording oxalic instead of mucous acid, when treated with nitric acid.—*Brande's Manual*, iii. 34.

British Oil. A variety of the black species of petroleum, to which this name has been given as an empirical remedy.

BROCATELLO. A calcareous stone or marble, composed of fragments of four colours, white, grey, yellow, and red.

BRO'CCOLI. *Brasica Italica.* As an article of diet, this may be considered as more delicious than cauliflower and cabbage. Sound stomachs digest broccoli without any inconvenience; but in dyspeptic stomachs, even when combined with pepper, &c. it always produces flatulency, and nauseous eructations.

BROCHOS. (Ερoχος, a snare.) A bandage.

BRO'CHTHUS. (From βρεχω, to pour.) The throat; also a small kind of drinking-vessel.

BRO'CHUS. Βροκὸς. One with a prominent upper-lip, or one with a full mouth and prominent teeth.

BROCKLESBY, RICHARD, was born in Somersetshire, though of an Irish family, in 1722. After studying at Edinburgh, he graduated at Leyden; then settled in London, but did not advance very rapidly in practice. About 1757, he was appointed physician to the army in Germany, and on his return after six years, published the result of his experience, in a work entitled "Economical and Medical Observations." His success now became more decided, and being prudent in his affairs, and without a family, he realised a considerable fortune. He proved himself however sufficiently liberal by presenting 1000*l.* to Mr. Edmund Burke, who had been his school-fellow; and by offering an annuity of 100*l.* to Dr. Johnson, to enable him to travel, which was not however accepted. He was author of several other works, and died in 1797.

BRO'DIUM. A term in pharmacy, signifying the same with *jusculum*, broth, or the liquor in which any thing is boiled. Thus we sometimes read of *brodium salis*, or a decoction of salt.

BRO'MA. (From βρωσκω, to eat.) Food of any kind that is masticated, and not drank.

BROMA-THEON. (From βρωσκω, to eat.) Mushrooms.

BROMATO'LOGY. (*Bromatologia*; from βρωμα, food, and λογος, a discourse.) A discourse or treatise on food.

BROME'LIA. (So named in honour of Olaus Bromel, a Swede, author of *Lupologia*, &c. in 1687.) The name of a genus of plants. Class, *Hexandria*; Order, *Monogynia*.

BROMELIA ANANAS. The systematic name of the plant which affords the pine apple, *Bromelia*:—*foliis ciliato spinosis, mucronatis, spica comosa* of Linnæus. It is used principally as a delicacy for the table, and is also given with advantage as a refrigerant in fevers.

BROMELIA KARATAS. The systematic name of the plant from which we obtain the fruit called penguin, which is given in the Spanish West Indies to cool and quench thirst in fevers, dysenteries, &c. It grows in a cluster, there being several of the size of one's finger together. Each portion is clothed with husk containing a white pulpy substance, which is the eatable part; and if it be not perfectly ripe, its flavour resembles that of the pine-apple. The juice of the ripe fruit is very austere, and is made use of to acidulate punch. The inhabitants of the West Indies make a wine of the penguin, which is very intoxicating, and has a good flavour.

BROMFIELD, WILLIAM, was born in London, 1712: and attained considerable reputation as a surgeon. At the age of twenty-nine he began to give anatomical lectures, which were very well attended. About three years after, in conjunction with the Rev. Mr. Madan, he formed the plan of the Lock Hospital; and so ably enforced the advantages of such an institution, that a sufficient fund was raised for erecting the present building; and it has been since maintained by voluntary contributions. He was appointed surgeon, and held that office for many years: he was also surgeon to St. George's Hospital, and to Her Majesty's household. He wrote many works; the most considerable was entitled "Chirurgical Cases and Observations," in 1773, but reckoned not to answer the expectations entertained of him. He attained his eightieth year.

BRO'MION. (From βρωμος, the oat.) The name of a plaster, made with oaten flour, mentioned by Paulus Ægineta.

BRO'MUS. (From βρωμα, food.) The name of a genus of plants in the Linnæan system. Class, *Triandria*; Order, *Dygynia*. Brome-grass.

BROMUS STERILIS. (From βρωσκω, to eat.) The wild oat.

BRO'NCHIA. (*Bronchia*, *orum.* neut. plur.; from βρογχος, the throat.) See *Trachea.*

BRONCHIAL. (*Bronchialis*; from *bronchia.*) Appertaining to the windpipe, or bronchia; as bronchial gland, artery, &c.

BRONCHIA'LIS. See *Bronchial.*

BRONCHIALES ARTERIÆ. Bronchial arteries. Branches of the aorta given off in the chest.

BRONCHIALES GLANDULÆ. Bronchial glands. Large blackish glands, situated about the bronchia and trachea.

BRONCHOCE'LE. (From βρογχος, the windpipe, and κηλη, a tumour.) *Botium*; *Hernia gutturis*; *Guttur tumidum*; *Trachelophyma*; *Gossum*; *Exechebronchos*; *Gongrona*; *Hernia bronchialis*; *Tracheocele.* Derbyshire neck. This disease is marked by a tumour on the forepart of the neck, and seated between the trachea and skin. In general it has been supposed principally to occupy the thyroid gland. We are given to understand that it is a very common disorder in Derbyshire; but its occurrence is by no means frequent in other parts of Great Britain, or in Ireland. Among the inhabitants of the Alps, and other mountainous countries bordering thereon, it is a disease very often met with, and is there known by the name of goitre. The cause which gives rise to it, is by no means certain, and the observations of different writers are of very little practical utility. Dr. Saunders controverts the general idea of the bronchocele being produced by the use of snow-water. The swelling is at first without pain, or any evident fluctuation; when the disease is of long standing, and the swelling considerable, we find it in general a very difficult matter to effect a cure by medicine, or any external application; and it might be unsafe to attempt its removal with a knife, on account of the enlarged state of its arteries, and its vicinity to the carotids; but in an early stage of the disease, by the aid of medicine, a cure may be effected.

Although some relief has been obtained at times, and the disease probably somewhat retarded by external applications, such as blisters, discutient embrocations, and saponaceous and mercurial plasters, still a complete cure has seldom been effected without an internal use of medicine; and that which has always proved the most efficacious, is burnt sponge. The form under which this is most usually exhibited, is that of a lozenge. ℞. spongiæ ustæ ℥ss. mucilag. Arab. gum. q. s. fiat trochiscus. When the tumour appears about the age of puberty, and before its structure has been too morbidly deranged, a pill consisting of a grain or two of calomel, must be given for three successive nights; and, on the fourth morning, a saline purge. Every night afterwards for three weeks, one of the troches should, when the patient is in bed, be put under the tongue, suffered to dissolve gradually, and the solution swallowed. The disgust at first arising from this remedy soon wears off. The pills and the purge are to be repeated at the end of three weeks, and the troches had recourse to as before; and this plan is to be pursued till the tumour is entirely dispersed. Some recommend the burnt sponge to be administered in larger doses. Sulphuretted potassa dissolved in water, in the proportion of 30 grains to a quart daily, is a remedy which has been employed by Dr. Richter with success, in some cases, where calcined sponge failed. The sodæ subcarbonas being the basis of burnt sponge, is now frequently employed instead of it, and, indeed, it is a more active medicine.

BRO'NCHOS. (Βρογχος, the windpipe.) A catarrh; a suppression of the voice from a catarrh.

BRONCHO'TOMY. (*Bronchotomia;* from βρογχος, the windpipe, and τεμνω, to cut.) Tracheotomy; Laryngotomy. This is an operation in which an opening is made into the larynx, or trachea, either for the purpose of making a passage for the air into and out of the lungs, when any disease prevents the patient from breathing through the mouth and nostrils, or of extracting foreign bodies, which have accidentally fallen into the trachea; or, lastly, in order to be able to inflate the lungs, in cases of sudden suffocation, drowning, &c. Its practicableness, and little danger, are founded on the facility with which certain wounds of the windpipe, even of the most complicated kind, have been healed, without leaving any ill effects whatever, and on the nature of the parts cut, which are not furnished with any vessel of consequence.

BRO'NCHUS. (From βρεχω, to pour.) The ancients believed that the solids were conveyed into the stomach by the œsophagus, and the fluids by the bronchia; whence its name. 1. The windpipe.

2. A defluxion from the fauces. See *Catarrhus.*

BRONZE. A mixed metal consisting chiefly of copper, with a small portion of tin, and sometimes other metals.

BRONZITE. A massive metal-like mineral, frequently resembling bronze, found in large masses in beds of serpentine, in Upper Stiria, and in Pertshire.

BROOKLIME. See *Veronica beccabunga.*

BROOM. See *Spartium scoparium.*

BROSIMUM. (From βρωσιμος, eatable.) The name of a genus of plants in the Linnæan system. Class, *Diœcia;* Order, *Monandria.*

BROSIMUM ALICASTRUM. The specific name of the tree, which affords the bread-nut.

BROWN, JOHN, born in the county of Berwick, in 1735. He made very rapid progress in his youth in the learned languages, and at the age of twenty went to Edinburgh to study theology; but before he could be ordained, became attached to free-living and free-thinking. About 1759, having translated the inaugural thesis of a medical candidate into Latin, and the performance being highly applauded, he was led to the study of medicine. The professors at Edinburgh allowed him to attend their lectures gratuitously; and he maintained himself by instructing the students in Latin, and composing or translating their dissertations. Dr. Cullen particularly encouraged him, notwithstanding his irregularities, employing him as tutor to his sons, and allowing him to repeat and enlarge upon his lectures in the evening to those pupils, who chose to attend. In 1765 he married, and his house was soon filled with boarders; but his imprudence brought on bankruptcy within four years after. About this period he was an unsuccessful candidate for one of the medical chairs; and attributing his failure to Dr. Cullen, became his declared enemy. This probably determined him to form his new system of medicine, afterwards published under the title of "Elementa Medicinæ:" in which certainly much genius is displayed, but little acquaintance with practice, or with what had been written before on the subject. His chief object seems to have been to reduce the medical art to the utmost simplicity: whence he arranged all diseases under the two divisions of sthenic and asthenic, and maintained that all agents operate on the body as stimuli; so that we had only to increase or diminish the force of these according to circumstances. At the head of his stimulant remedies he places wine, brandy, and opium, in the recommendation of which he is very liberal; and especially betrays his partiality to them by asserting, contrary to universal experience, that he found them in his own person the best preservatives against the gout. He is said to have prepared himself for his lectures by a large dose of laudanum in whiskey; and thus roused himself to a degree of enthusiasm, bordering on frenzy. After completing his work, he procured a degree from St. Andrew's, and commenced public teacher. The novelty and imposing simplicity of his doctrines procured him at first a pretty numerous class: but being irregular in his attendance, and his habits of intemperance increasing, they fell off by degrees: and he was at length so embarrassed, as to be obliged to quit Edinburgh in 1786. He then settled in London, but met with little success, and in about two years after died. His opinions at first found many supporters, as well in this as in other countries; but they appear now nearly fallen into deserved oblivion.

BROWN SPAR. Pearl spar. Sideroculcite. A white, red, or brown, or black-spar; harder than the calcareous, but yields to the knife.

BROWNE, SIR THOMAS, was born in Cheapside, 1605. After studying and practising for a short time at Oxford, he spent about three years in travelling, graduating at length at Leyden. He then came to London, and published his "Religio Medici;" which excited great attention as a work of genius, though blemished by a few of the popular superstitions then prevailing. He soon after settled at Norwich, and got into very good practice; and was admitted an honorary member of the London College of Physicians. In 1646 appeared his most popular work "On Vulgar Errors," which added greatly to his fame; though he injudiciously ranked the Copernican system among them. He was knighted by Charles II.; and died at the termination of his 77th year. His son Edward was also a physician, and attained considerable eminence, having had the honour of attending Charles II. and William III., and being for three years president of the college.

BRU'CEA. (So named by Sir Joseph Banks, in honour of Mr. Bruce, the traveller in Abyssinia, who first brought the seeds thence into England.) The name of a genus of plants in the Linnæan system. Class, *Diœcia;* Order, *Tetrandria.*

BRUCEA ANTIDYSENTERICA. The systematic name of the plant from which it was erroneously supposed we obtained the angustura bark. See *Cusparia.*

BRUCEA FERRUGINEA. This plant was also supposed to afford the angustura bark.

BRUCIA. Brucine. A new vegetable alkali, lately extracted from the bark of the false angustura, or *Brucia antidysenterica,* by Pelletier and Caventou. After being treated with sulphuric æther, to get rid of a fatty matter, it was subjected to the action of alkohol. The dry residuum, from the evaporated alcoholic solution, was treated with Goulard's extract, or solution of acetate of lead, to throw down the colouring matter, and the excess of lead was separated by a current of sulphuretted hydrogen. The nearly colourless alkaline liquid was saturated with oxalic acid, and evaporated to dryness. The saline mass being freed from its remaining colouring particles by absolute alkohol, was then decomposed by lime or magnesia, when the *brucia* was disengaged. It was dissolved in boiling alkohol, and obtained in crystals, by the slow evaporation of the liquid. These crystals, when obtained by very slow evaporation, are oblique prisms, the bases of which are parallelograms. When deposited from a saturated solution in boiling water, by cooling, it is in bulky plates, somewhat similar to boracic acid in appearance. It is soluble in 500 times its weight of boiling water, and in 850 of cold. Its solubility is much increased by the colouring matter of the bark.

Its taste is exceedingly bitter, acrid, and durable in the mouth. When administered in doses of a few grains, it is poisonous, acting on animals like strychnia, but much less violently. It is not affected by the air. The dry crystals fuse at a temperature a little above that of boiling water, and assume the appearance of wax. At a strong heat it is resolved into carbon, hydrogen, and oxygen; without any trace of azote. It combines with the acids, and forms both neutral and super-salts.

BRUCINE. See *Brucia.*

BRUISEWORT. See *Saponaria.*

BRUMALIS. (From *Bruma,* winter.) *Hyemalis.* Belonging to winter.

BRUMALES PLANTÆ. Plants which flower in our winter, common about the cape.

BRUNE'LLA. See *Prunella.*

BRUNNER, JOHN CONRAD, was born in Switzerland in 1653. He obtained his degree in medicine at Strasburg when only nineteen. He afterwards spent several years in improving himself at different universities, particularly at Paris; where he made many experiments on the pancreas, and found that it might be removed from a dog with impunity. On his return he was made professor of medicine at Heidelberg; and gained great reputation, so as to be consulted by most of the princes of Germany. He discovered the mucous glands in the duodenum; and was author of several inconsiderable works. He died in 1727.

BRUNNER'S GLANDS. *Brunneri glandulæ.* Peyer's glands. The muciparous glands, situated between the villous and cellular coat of the intestinal canal; so named after Brunner, who discovered them.

BRUNSWICK GREEN. An ammoniaco-muriate of copper.

BRUNTKUP FERZ. Purple copper ore.

BRU'NUS. An erysipelatous eruption.

BRU'SCUS. See *Ruscus.*

BRUT'A. An Arabian word which means instinct, and is also applied to Savine.

BRU'TIA. An epithet for the most resinous kind of pitch, therefore used to make the *Oleum Picinum.* The *Pix Brucia* was so called from Brutia, a country in the extreme parts of Italy, where it was produced.

BRUTI'NO. Turpentine.

BRU'TOBON. The name of an ointment used by the Greeks.

BRUTUA. See *Cissampelos Pareira.*

BRUXANE'LI. (Indian.) A tall tree in Malabar, the bark of which is diuretic.

BRY'GMUS. (From βρυχω, to make a noise.) A peculiar kind of noise, such as is made by gnashing or grating the teeth; or, according to some, a certain kind of convulsion affecting the lower jaw, and striking the teeth together, most frequently observed in such children as have worms.

BRYO'NIA. (From βρυω, to abound, from its abundance.) Bryony. 1. The name of a genus of plants in the Linnæan system. Class, *Diœcia;* Order, *Syngenesia.*

2. The pharmacopœial name of the white bryony. See *Bryonia alba.*

BRYONIA ALBA. The systematic name of the white bryony plant. *Vitis alba sylvestris; Agrostis; Anpelo sagria; Archeostris; Echetrosis* of Hippocrates. *Bryonia aspera; Cedrostis; Chelidonium; Labrusca; Melothrum Ophrostaphylon; Psilothrum. Bryonia—foliis palmatis utrinque calloso-scabris* of Linnæus. This plant is very common in woods and hedges. The root has a very nauseous biting taste, and disagreeable smell. Bergius states the virtues of this root to be purgative, hydragogue, emmenagogue, and diuretic; the fresh root emetic. This powerful and irritating cathartic, though now seldom prescribed by physicians, is said to be of great efficacy in evacuating serous humours, and has been chiefly employed in hydropical cases. Instances of its good effects in other chronic diseases are also mentioned; as asthma, mania, and epilepsy. In small doses, it is reported to operate as a diuretic, and to be resolvent and deobstruent. In powder, from ℈j. to a drachm, it proves strongly purgative, and the juice, which issues spontaneously, in doses of a spoonful or more, has similar effects, but is more gentle in its operation. An extract prepared by water, acts more mildly, and with greater safety than the root in substance, given from half a drachm to a drachm. It is said to prove a gentle purgative, and likewise to operate powerfully by urine. Of the expressed juice, a spoonful acts violently both upwards and downwards; but cream of tartar is said to take off its virulence. Externally, the fresh root has been employed in cataplasms, as are solvent and discutient; also in ischiadic and other rheumatic affections.

BRYONIA MECHOACHANA NIGRICANS. A name given to the jalap root.

BRYONIA NIGRA. See *Tamus communis.*

BRYONIA PERUVIANA. Jalap.

BRY′ONY. See *Bryonia nigra.*

Bryony, black. See *Tamus.*

Bryony, white. See *Bryonia alba.*

BRY′THION. Βρυθιον. A malagma; so called and described by Paulus Ægineta.

BRY′TON. (From *βρυω*, to pour out.) A kind of ale, or wine, made of barley.

BUBASTECO′RDIUM. (From *bubastus* and *cor*, the heart.) A name formerly given to artemisia, or mugwort.

BU′BO. (From *βουβων*, the groin; because they most frequently happen in that part.) Modern surgeons mean, by this term, a swelling of the lymphatic glands, particularly of those of the groin and axilla. The disease may arise from the mere irritation of some local disorder, when it is called *sympathetic bubo;* from the absorption of some irritating matter, such as the venereal poison; or from constitutional causes, as in the pestilential bubo, and scrophulous swellings, of the inguinal and axillary glands.

BU′BON. (From *βουβων*, the groin, or a tumour to which that part is liable, and which it was supposed to cure.) The name of a genus of plants in the Linnæan system. Class, *Pentandria;* Order, *Digynia.*

BUBON GALBANUM. The systematic name of the plant which affords the officinal galbanum. *Albetad; Chalbane; Gesor.* The plant is also named *Ferula Africana; Oreoselinum Africanum; Anisum fruticosum galbaniferum; Anisum Africanum fruticescens; Ayborzat.* The lovage-leaved bubon. *Bubon; foliis rhombeis dentatis striatis glabris, umbellis paucis,* of Linnæus. Galbanum is the gummi-resinous juice, obtained partly by its spontaneous exudation from the joints of the stem, but more generally, and in greater abundance, by making an incision in the stalk, a few inches above the root, from which it immediately issues, and soon becomes sufficiently concrete to be gathered. It is imported into England from Turkey, and the East Indies, in large, softish, ductile, pale-coloured masses, which, by age, acquire a brownish-yellow appearance: these are intermixed with distinct whitish tears, that are the most pure part of the mass. Galbanum has a strong unpleasant smell, and a warm, bitterish, acrid taste. Like the other gummy resins, it unites with water, by trituration into a milky liquor, but does not perfectly dissolve, as some have reported, in water, vinegar, or wine. Rectified spirit takes up much more than either of these menstrua, but not the whole: the tincture is of a bright golden colour. A mixture of two parts of rectified spirit, and one of water, dissolves all but the impurities, which are commonly in considerable quantity. In distillation with water, the oil separates and rises to the surface, in colour yellowish, in quantity one-twentieth of the weight of the galbanum. Galbanum medicinally considered, may be said to hold a middle rank between assafœtida and ammoniacum; but its fœtidness is very inconsiderable, especially when compared with the former: it is therefore accounted less antispasmodic, nor are its expectorant qualities equal to those of the latter; it however is esteemed more efficacious than either in hysterical disorders. Externally, it is often applied, by surgeons, to expedite the suppuration of inflammatory and indolent tumours, and, by physicians, as a warm stimulating plaster. It is an ingredient in the *pilulæ galbani compositæ,* the *emplastrum galbani compositum* of the London Pharmacopœia, and in the *emplastrum gummosum* of the Edinburgh.

BUBON MACEDONICUM. The systematic name of the plant which affords the *semen petroselini Macedonici* of the shops. *Apium petræum; Petrapium.* Macedonian parsley. This plant is similar in quality to the common parsley, but weaker and less grateful. The seeds enter the celebrated compounds mithridate and theriaca.

BUBO′NIUM. (From *βουβων*, the groin.) A name of the golden starwort; so called because it was supposed to be efficacious in diseases of the groin.

BUBONOCE′LE. (From *βουβων*, the groin, and *κηλη*, a tumour.) *Hernia inguinalis.* Inguinal hernia, or rupture of the groin. A species of hernia, in which the bowels protrude, at the abdominal ring. See *Hernia inguinalis.*

BU′CCA. (Hebrew.) The cheek. The hollow inner part of the cheek, that is inflated by the act of blowing.

BUCCACRA′TON. (From *bucca*, or *buccella*, and *κραω*, to mix.) A morsel of bread sopped in wine, which served in old times for a breakfast.

BU′CCAL. (From *bucca*, the cheek.) Belonging to the cheek.

BUCCINALES GLANDULÆ. The small glands of the mouth, under the cheek, which assist in secreting saliva into that cavity.

BU′CCEA. (From *bucca*, the cheek; as much as can be contained at one time within the cheeks.) 1. A mouthful; a morsel.

2. A polypus of the nose.

BUCCELA′TON. (From *buccella*, a morsel.) A purging medicine, made up in the form of a loaf; consisting of scammony, &c. put into fermented flour, and then baked in an oven.

BUCCE′LLA. Paracelsus calls the polypus in the nose by this name, because he supposes it to be a portion of flesh parting from the bucca, and insinuating itself into the nose.

BUCCELLA′TIO. (From *buccellatus*, cut into small pieces.) *Baccellatio.* A method of stopping an hæmorrhage, by applying small pieces of lint to the vein, or artery.

BUCCINA′TOR. (From *βουκανον*, a trumpet; so named from its use in forcing the breath to sound the trumpet.) *Retractor anguli oris* of Albinus, and *alveolo-maxillaire* of Dumas. The trumpeter's muscle. The buccinator was long thought to be a muscle of the lower jaw, arising from the upper alveoli, and inserted into the lower alveoli, to pull the jaw upwards; but its origin and insertion, and the direction of its fibres, are quite the reverse of this. For this large flat muscle, which forms in a manner the walls of the cheek, arises chiefly from the coronoid process of the lower jaw-bone, and partly also from the end of the alveoli, or socket process of the upper jaw, close by the pterygoid process of the sphenoid bone; it goes forward, with direct fibres, to be implanted into the corner of the mouth; it is thin and flat, covers in the mouth, and forms the walls of the cheek, and is perforated in the middle of the cheek by the duct of the parotid gland. These are its principal uses:—it flattens the cheek, and so assists in swallowing liquids; it turns, or helps to turn, the morsel in the mouth while chewing, and prevents it from getting without the line of the teeth; in blowing wind instruments, it both receives and expels the wind; it dilates like a bag, so as to receive the wind in the cheeks; and it contracts upon the wind, so as to expel the wind, and to swell the note. In blowing the strong wind instruments, we cannot blow from the lungs, for it distresses the breathing, we reserve the air in the mouth, which we keep continually full; and from this circumstance, as mentioned above, it is named buccinator, from blowing the trumpet.

Bu′ccula. (Diminutive of *bucca*, the cheek.) The fleshy part under the chin.

Bucephalon, red-fruited. See *Trophis Americana.*

Bu′ceras. (From βους, an ox, and κερας, a horn: so called from the horn-like appearance of its seed.) *Buceros.* See *Trigonnella Fœnumgræcum.*

BUCHAN, William, was born at Ancram, in 1729. After studying at Edinburgh, he settled in Sheffield, and was soon appointed physician to the Foundling Hospital at Ackworth: but that establishment being afterwards given up, he went to practise at Edinburgh, where he remained several years. During that period he composed his celebrated Work, called "Domestic Medicine," on the plan of Tissot's "Avis aux Peuples;" which has been very extensively circulated, translated into other languages, and obtained the author a gold medal, with a commendatory letter, from the Empress of Russia. It has been objected, that such publications tend to degrade and injure the medical profession; but it does not appear that those, who are properly qualified, can suffer permanently thereby. There seems more foundation for the opinion, that imaginary diseases will be multiplied, and patients sometimes fall victims to their complaints, being treated by those, who do not properly understand them. Dr. Buchan afterwards practised in London, and published some other works; and died in 1805.

BUCK-BEAN. See *Menyanthes trifoliata.*

BUCK-THORN. See *Rhamnus catharticus.*

BUCK-WHEAT. See *Polygonum fagopyrum.*

Buck-wheat, eastern. See *Polygonum divaricatum.*

BUCNEMIA. (*Bucnemia*; from βου, a Greek augment, and κνημη, the leg.) A name in Good's Nosology for a genus of disease characterised by a tense, diffuse, inflammatory swelling of a lower extremity; usually commencing at the inguinal glands, and extending in the course of the lymphatics, it embraces two species: 1. *Bucnemia sparganosis*, the puerperal tumid leg. 2. *Bucnemia tropica*, the tumid leg of hot climates.

Bucra′nion. (From βους, an ox, and κρανιον, the head; so called from its supposed resemblance to a calf's snout.) The Snap-dragon plant. See *Antirrhinum.*

Bu′cton. The hymen, according to Piræus.

Buga′ntia. Chilblains.

BUGLE. See *Prunella.*

BUGLOSS. See *Anchusa officinalis.*

Buglo′ssa. See *Anchusa officinalis.*

BUGLO′SSUM. (*Buglossum*, i. n.; from βους, an ox, and γλωσσα, a tongue: so called from the shape and roughness of its leaf.) See *Anchusa officinalis.*

Buglossum angustifolium. See *Anchusa officinalis.*

Buglossum majus. See *Anchusa officinalis.*

Buglossum sativum. See *Anchusa officinalis.*

Buglossum sylvestre. The stone bugloss.

Bu′gula. (A diminutive of *buglossa.*) See *Ajuga pyramidalis.*

BULBIFERUS. (From *bulbus*, and *fero*, to bear.) Bulb-bearing. Having one or more bulbs; applied to stems, *Caulis bulbiferus.*

BULBOCA′STANUM. (From βολβος, a bulb, and καϛανον, a chesnut: so called from its bulbous appearance.) See *Bunium bulbocastanum.*

BULBOCAVERNO′SUS. (So called from its origin and insertion.) See *Accelerator urinæ.*

Bu′lbonach. See *Lunaria rediviva.*

BULBOSUS. (From *bulba*, a bulb.) Bulbous: applied in anatomy to soft parts which are naturally enlarged, as the bulbous part of the urethra. In botany, to roots which have a bulb; as tulip, onion, lily, &c.

Bulbosæ. (From *bulbus.*) The name of a class of *Cæsalpinus's* systematic method, consisting of herbaceous vegetables, which have a bulbous root, and a pericarpium, divided into three cells; also the name of one of the natural orders of plants.

BULBULUS. A little bulb.

BUL′BUS. (Βολβος, a bulb, or somewhat rounded root.) A globular, or pyriform coated body, solid, or formed of fleshy scales or layers, constituting the lower part of some plants, and giving off radicles from the circumference of the flattened basis. A bulb differs from a *tuber*, which is a farinaceous root, and sends off radicles in every direction.

Bulbs are divided into,

1. The *solid*, which consists of a solid fleshy nutritious substance; as in *Crocus sativus Colchicum autumnale, Tulipa gesneriana.*

2. The *scaly*, which consists of fleshy concentrical scales attached to a radical plate; as in *Allium cepa.*

3. The *squamose*, consisting of concave, overlapping scales; as in *Lilium candidum*, and *Lilium bulbiferum.*

4. The *compounded*, consisting of several lesser bulbs, lying close to each other; as in *Allium sativum.*

The bulbs of the orchis tribe differ from the common bulbs in not sending off radicles from the lower part, but from between the stem and basis. These are distinguished into,

5. The *testiculate*, having two bulbs of a round-oblong form; as in *Orchis morio*, and *Orchis mascula.*

6. *Palmate*, a compressed bulb, hand-like, divided below into finger-like lobes; as in *Orchis maculata.*

Bulbus esculentus. Such bulbous roots as are commonly eaten are so called.

Bulbus vomitorius. See *Hyacinthus muscari.*

BULGE-WATER-TREE. The *Geoffroya jamaicensis.*

BULI′MIA. (From βου, a particle of excess, and λιμος, hunger.) *Bulimiasis; Boulimos; Bulimus; Bolismos* of Avicenna. *Fames canina; Appetitus caninus; Phagedæna; Adephagia; Bupeina; Cynorexia.* Insatiable hunger, or canine appetite.

Dr. Cullen places this genus of disease in the class *Locales*, and order *Dysorexiæ*; and distinguishes three species. 1. *Bulimia helluonum*; in which there is no other disorder of the stomach, than an excessive craving of food. 2. *Bulimia syncopalis*; in which there is a frequent desire of food, and the sense of hunger is preceded by swooning. 3. *Bulimia emetica*, also *cynorexia*; in which an extraordinary appetite for food is followed by vomiting. The real causes of this disease are, perhaps, not properly understood.

In some cases, it has been supposed to proceed from an acid in the stomach, and in others, from a superabundance of acid in the gastric juice, and from indigested sordes, or worms. Some consider it as depending more frequently on monstrosity than disease. An extraordinary and well-attested case of this disease, is related in the third volume of the Medical and Physical Journal, of a French prisoner, who in one day, consumed of raw cow's udder 4 lb., raw beef 10 lbs., candles 2 lbs.; total, 16 lbs.; besides 5 bottles of porter.

Bulimia addephagia. A voracious appetite.

Bulimia canina. A voracious appetite, with subsequent vomiting.

Bulimia cardialgica. A voracious appetite, with heartburn.

Bulimia convulsorum. A voracious appetite, which attends some convulsive diseases.

Bulimia emetica. A voracious appetite, with vomiting.

Bulimia esurigio. Gluttony.

Bulimia helluonum. Gluttony.

Bulimia syncopalis. A voracious appetite, with fainting from hunger.

Bulimia verminosa. A voracious appetite from worms.

BULIMI'ASIS. See *Bulimia.*

BU'LIMUS. See *Bulimia.*

BULI'THUM. (From βους, an ox, and λιθος, a stone.) A bezoar, or stone found in the kidneys, or gall, or urinary bladder, of an ox, or cow.

BU'LLA. A bubble. A clear vesicle, which arises from burns, or scalds; or other causes.

BU'LLACE. The English name of the fruit of the *Prunus insitia* of Linnæus, which grows wild in our hedges. There are two varieties of bullace, the red and the white, which are used with the same intention as the common damsons.

BULLATUS. (From *bulla*, a bubble, or blister.) Blistery. Applied to a leaf which has its veins so tight, that the intermediate space appears blistered. This appearance is frequent in the garden cabbage.

Bullo'sa febris. An epithet applied to the vesicular fever, because the skin is covered with little vesicles, or blisters. See *Pemphigus.*

Buni'tes vinum. (From *bunium*, wild parsley.) Wine made of bunium and must.

BU'NIUM. (From βουνος, a little hill; so called from the tuberosity of its root.) 1. The name of a genus of plants in the Linnæan system. Class, *Pentandria;* Order, *Digynia.*

2. The name of the wild parsley.

Bunium bulbocastanum. The systematic name of a plant, the root of which is called the pig-nut. *Agriocastanum; Nucula terrestris; Bulbocastaneum; Bulbocastanum majus et minus.* Earth-nut; Hawk-nut; Kipper-nut; and Pig-nut. The root is as large as a nutmeg; hard, tuberous, and whitish; which is eaten raw, or roasted. It is sweetish to the taste, nourishing, and supposed to be of use against strangury and bloody urine. The roots, which are frequently ploughed up by the peasants of Burgundy, and called by them *arnotta;* and those found in Scotland, and called *arnots*, are most probably the roots of this species of bunium. They are roasted, and thus acquire the flavour of chesnuts.

Bu'nias. A species of turnip.

BU'PEINA. (From βου, a particle of magnitude, and ϖεινα hunger.) A voracious appetite.

BU'PHAGOS. (From βου, a particle of excess, and φαγω, to eat.) The name of an antidote which created a voracious appetite in Marcellus Empericus.

BUPHTHA'LMUM. (From βους, an ox, and οφθαλμος, an eye; so called from its flowers, which are supposed to resemble an eye.) The herb, ox-eye daisy. See *Crysanthemum leucanthemum.*

Buphthalmum creticum. Pellitory of Spain. See *Anthemis pyrethrum.*

Buphthalmum germanicum. The common ox-eye daisy.

Buphthalmum majus. Great, or ox-eye daisy. See *Chrysanthemum leucanthemum.*

BUPHTHALMUS. (From βους, an ox, and οφθαλμος, an eye; so named from its large appearance like an ox's eye.)

1. Houseleek.

2. Diseased enlargement of the eye.

BUPLEU'RUM. (From βου, large, and ϖλεὺρον, a rib; so named from its having large rib-like filaments upon its leaves. 1. The name of a genus of plants in the Linnæan system. Class, *Syngenesia;* Order, *Polygamia superflua.*

2. The pharmacopœial name of the herb hare's ear. See *Bupleurum rotundifolium.*

Bupleurum rotundifolium. The systematic name of the plant called *perfoliata*, in some pharmacopœias. *Bupleuron; Bupleuroides.* Round-leaved hare's ear, or thorow wax. This plant was formerly celebrated for curing ruptures, mixed into a poultice with wine and oatmeal.

Bu'rac. (An Arabian word.) Borax, or any kind of salt.

BU'RDOCK. See *Arctium lappa.*

BU'RGUNDY PITCH. See *Pinus abies.*

Bu'ris. According to Avicenna, a scirrhous hernia, or hard abscess.

BURN. *Ambustio.* A burn, or scald, is a lesion of the animal body, occasioned by the application of heat, but the latter term is applicable only where this is conveyed through the medium of some fluid. The consequences are more or less serious according to the extent of the injury, or the particular part affected: sometimes even proving fatal, particularly in irritable constitutions. The life of the part may be at once destroyed by these accidents, or mortification speedily follow the violent inflammation excited; but when slighter, it usually produces an effusion of serum under the cuticle, like a blister. When the injury is extensive, considerable fever is apt to supervene, sometimes a comatose state; and a remarkable difficulty of breathing often precedes death. In the treatment of these accidents, two very different methods have been pursued. The more ancient plan consists in antiphlogistic means, giving cooling purgatives, &c. and even taking blood, where the irritation is great; employing at the same time cold applications, and where the skin is destroyed, emollient dressings; opium was also recommended to relieve the pain, notwithstanding stupor might attend.

Mr. Cleghorn, a brewer at Edinburgh, was very successful in these cases by a treatment materially different; first bathing the part with vinegar, usually a little warmed, till the pain abated; then, if there were any destruction of the parts, applying poultices, and finely-powdered chalk immediately on the sore, to absorb the discharge: in the mean time allowing the patient to live pretty well, and abstaining from active purgatives, &c. More recently, a surgeon at Newcastle, of the name of Kentish, has deviated still more from the ancient practice; applying first oil of turpentine, alcohol, &c. heated as much as the sound parts could bear, and gradually lessening the stimulus; in the mean time supporting the patient by a cordial diet, æther, &c. and giving opium largely to lessen the irritation. Now, the cases chiefly under his care were of persons scorched very extensively by the explosion of carburetted hydrogen in mines; and probably where the injury is over a large part of the surface, or where the constitution is weakly, it may be hazardous to pursue the antiphlogistic plan, or to use cold applications, which, while intended to keep down action, are wearing out the power of the part. If any extraneous substance be forced into the burnt part, it should be of course removed: and sometimes where a limb is irrecoverably injured, amputation may be necessary.

Bu'rnea. Pitch.

Burnet saxifrage. See *Pimpinella.*

Burning. *Brenning.* An ancient medical term, denoting an infectious disease, got in the stews by conversing with lewd women, and supposed to be the same with what we now call the venereal disease.

Burnt hartshorn. See *Cornu ustum.*

Burnt sponge. See *Spongia usta.*

Bu'rrhi spiritus matricalis. Burrhus's spirit, for disorders of the womb. A compound of myrrh, olibanum, amber, and spirit of wine.

BU'RSA. (From *βυρσα*, a bag.) A bag. 1. The scrotum.

2. An herb called *Thlaspi bursæ pastoris*, from the resemblance of its seminal follicles to a triangular purse.

Bursa mucosa. A mucous bag, composed of proper membranes, containing a kind of mucous fat, formed by the exhaling arteries of the internal coat. The bursæ mucosæ are of different sizes and firmness, and are connected by the cellular membrane with articular cavities, tendons, ligaments, or the periosteum. Their use is to secrete and contain a substance to lubricate tendons, muscles, and bones, in order to render their motion easy.

A Table of all the Bursæ Mucosæ.

In the Head.

1. *A bursa of the superior oblique muscle* of the eye, situated behind its trochlea in the orbit.

2. *The bursa of the digastricus,* situated in the internal surface of its tendon.

3. *A bursa of the circumflexus,* or tensor palati, situated between the hook-like process of the sphenoid bone and the tendon of that muscle.

4. *A bursa of the sterno-hyoideus muscle,* situated between the os hyoides and larynx.

About the Shoulder-joint.

1. *The external acromial,* situated under the acromion, between the coracoid process, deltoid muscle, and capsular ligament.

2. *The internal acromial,* situated above the tendon of the infra-spinatus and teres major: it often communicates with the former.

3. *The coracoid bursa,* situated near the root of the coracoid process; it is sometimes double and sometimes triple.

4. *The clavicula bursa,* found where the clavicle touches the coracoid process.

5. *The subclavian bursa,* between the tendon of the subclavius muscle and the first rib.

6. *The coraco-brachial,* placed between the common origin of this muscle and the biceps, and the capsular ligament.

7. *The bursa of the pectoralis major,* situated under the head of the humerus, between the internal surface of the tendon of that muscle, and another bursa placed on the long head of the biceps.

8. *An external bursa of the teres major,* under the head of the os humeri, between it and the tendon of the teres major.

9. *An internal bursa of the teres major,* found within the muscle where the fibres of its tendon diverge.

10. *A bursa of the latissimus dorsi,* between the tendon of this muscle and the os humeri.

11. *The humero-bicipital bursa,* in the vagina of the tendon of the biceps.

There are other bursæ mucosæ about the humerus, but their situation is uncertain.

Near the Elbow-joint.

1. *The radio-bicipital* is situated between the tendon of the biceps, brachialis, and anterior tubercle of the radius.

2. *The cubito-radial* between the tendon of the biceps, supinator brevis, and the ligament common to the radius and ulna.

3. *The anconeal bursa,* between the olecranon and tendon of the anconeus muscle.

4. *The capitulo-radial bursa,* between the tendon common to the extensor carpi radialis brevis, and extensor communis digitorum, and round head of the radius. There are occasionally other bursæ; but as their situation varies, they are omitted.

About the inferior part of the Fore-arm and Hand.

On the inside of the Wrist and Hand.

1. A very *large bursa,* for the tendon of the flexor pollicis longus.

2. *Four short bursæ* on the fore-part of the tendons of the flexor sublimis.

3. *A large bursa* behind the tendon of the flexor pollicis longus, between it and the fore-part of the radius, capsular ligament of the wrist and os trapezium.

4. *A large bursa* behind the tendons of the flexor digitorum profundus, and on the fore-part of the end of the radius, and fore-part of the capsular ligament of the wrist. In some subjects it communicates with the former.

5. *An oblong bursa* between the tendon of the flexor carpi radialis and os trapezium.

6. *A very small bursa* between the tendon of the flexor carpi ulnaris and os pisiforme.

On the back part of the Wrist and Hand.

7. *A bursa* between the tendon of the abductor pollicis longus and the radius.

8. *A large bursa* between the two extensores carpi radiales.

9. *Another* below it, common to the extensores carpi radiales.

10. *A bursa,* at the insertion of the tendon of the extensor carpi radialis.

11. *An oblong bursa,* for the tendon of the extensor pollicis longus, and which communicates with 9.

12. *A bursa,* for the tendon of the extensor pollicis longus, between it and the metacarpal bone of the thumb.

13. *A bursa* between the tendons of the extensor of the fore, middle, and ring fingers.

14. *A bursa* for the extensors of the little finger.

15. *A bursa* between the tendon of the extensor carpi ulnaris and ligament of the wrist.

There are also bursæ mucosæ between the musculi lumbricales and interossei.

Near the hip-joint.

On the fore-part of the joint.

1. *The ileo-puberal,* situated between the ilia-

cus internus, psoas magnus, and the capsular ligament of the head of the femur.

2. *The pectineal*, between the tendon of the pectineus and the thigh-bone.

3. *A small bursa* of the gluteus medius muscle, situated between it and the great trochanter, before the insertion of the pyriformis.

4. *A bursa* of the gluteus minimus muscle between its tendon and the great trochanter.

5. *The gluteo-fascial*, between the gluteus maximus and vastus externus.

On the posterior part of the Hip-joint.

6. *The tubero-ischiatic bursa*, situated between the obturator internus muscle, the posterior spine of the ischium, and its tuberosity.

7. *The obturatory bursa*, which is oblong and found between the obturator internu and gemini muscles, and the capsular ligament.

8. *A bursa of the semi-membranosus* under its origin and the long head of the biceps femoris.

9. *The gluteo trochanteral bursa*, situated between the tendon of the psoas muscle and the root of the great trochanter.

10. *Two gluteo-femoral bursæ*, situated between the tendon of the gluteus maximus and os femoris.

11. *A bursa of the quadratus femoris*, situated between it and the little trochanter.

12. *The iliac bursa*, situated between the tendon of the iliacus internus and the little trochanter,

Near the Knee-joint.

1. *The supra-genual*, which adheres to the tendons of the vastus and cruralis and the fore-part of the thigh-bone.

2. *The infra-genual bursa*, situated under the ligament of the patella, and often communicating with the above.

3. *The anterior genual*, placed between the tendon of the sartorius, gracilis, and semitendinosus, and the internal and lateral ligament of the knee.

4. *The posterior genual*, which is sometimes double, and is situated between the tendons of the semi-membranosus, the internal head of the gastrocnemius, the capsular ligament, and internal condyle.

5. *The popliteal*, conspicuous between the tendon of that muscle, the external condyle of the femur, the semilunar cartilage, and external condyle of the tibia.

6. *The bursa of the biceps cruris*, between the external part of the tendon, the biceps cruris, and the external lateral ligament of the knee.

In the Foot.

On the back, side, and hind-part of the Foot.

1. *A bursa of the tibialis anticus*, between its tendon, the lower part of the tibia, and capsular ligament of the ankle.

2. *A bursa* between the tendon of the extensor pollicis pedis longus, the tibia and capsular ligament of the ankle.

3. *A bursa of the extensor digitorum communis*, between its tendons, the tibia, and ligament of the ankle.

4. *A large bursa*, common to the tendons of the peronei muscles.

5. *A bursa of the peroneus brevis*, proper to its tendon.

6. *The calcaneal bursa*, between the tendo Achillis and os calcis.

In the Sole of the Foot.

1. *A bursa for the tendon of the peroneus longus.*

2. *A bursa* common to the tendon of the flexor pollicis pedis longus, and the tendon of the flexor digitorum pedis communis longus profundus.

3. *A bursa of the tibialis posticus*, between its tendon, the tibia, and astragalus.

4. *Five bursæ for the flexor tendons*, which begin a little above the first joint of each toe, and extend to the root of the third phalanx, or insertion of the tendons.

BURSA'LIS. From its resemblance to a bursa, or purse. See *Obturator externus et internus.*

BURSA'LOGY. (*Bursalogia*; from *βυρσα*, a bag, and *λογος*, a discourse.) The doctrine of the bursæ mucosæ.

BUSELI'NUM. (From *βου*, great, and *σελινον*, parsley.) A large species of parsley.

BU'SSII SPIRITUS BEZOARDICUS. The bezoardic spirit of Bussius, an eminent physician at Dresden. A distillation of ivory, sal-ammoniac, amber, &c.

BUTCHERSBROOM. See *Ruscus.*

BU'TIGA. Small red pimples on the face. Called also *gutta rosacea.*

BU'TINO. Turpentine.

BU'TOMON. See *Iris pseudacorus.*

BUTTER. (*Butyrum*; from *βους*, a cow, and *τυρος*, *coagulum*, or cream.) "The oily inflammable part of milk, which is prepared in many countries as an article of food. The common mode of preserving it is by the addition of salt, which will keep it good a considerable time, if in sufficient quantity. Mr. Eaton informs us, in his Survey of the Turkish Empire, that most of the butter used at Constantinople is brought from the Crimea and Kirban, and that it is kept sweet, by melting it while fresh over a very slow fire, and removing the scum as it rises. He adds, that by melting butter in the Tartarian manner, and then salting it in ours, he kept it good and fine-tasted for two years; and that this melting, if carefully done, injures neither the taste nor colour. Thenard, too, recommends the Tartarian method. He directs the melting to be done on a water-bath, or at a heat not exceeding 180° F.; and to be continued till all the caseous matter has subsided to the bottom, and the butter is transparent. It is then to be decanted, or strained through a cloth, and cooled in a mixture of pounded ice and salt, or at least in cold spring water, otherwise it will become lumpy by crystallizing, and likewise not resist the action of the air so well. Kept in a close vessel, and in a cool place, it will thus remain six months or more, nearly as good as at first, particularly after the top is taken off. If beaten up with one-sixth of its weight of the cheesy matter when used, it will in some degree resemble fresh butter in appearance. The taste of rancid butter, he adds, may be much corrected by melting and cooling in this manner.

Dr. Anderson has recommended another mode of curing butter, which is as follows: Take one part of sugar, one of nitre, and two of the best Spanish great salt, and rub them together into a fine powder. This composition is to be mixed thoroughly with the butter, as soon as it is completely freed from the milk, in the proportion of one ounce to sixteen; and the butter thus prepared is to be pressed tight into the vessel prepared for it, so as to leave no vacuities. This butter does not taste well, till it has stood at least a fortnight; it then has a rich marrow flavour, that no other butter ever acquires; and with proper care may be kept for years in this climate, or carried to the East Indies, if packed so as not to melt.

In the interior parts of Africa, Mr. Park informs us, there is a tree much resembling the American oak, producing a nut in appearance somewhat like an olive. The kernel of this nut, by boiling in water, affords a kind of butter, which is whiter, firmer, and of a richer flavour, than any he ever tasted made from cow's milk, and will keep without salt the whole year. The natives call it *shea toulou*, or tree butter. Large quantities of it are made every season."

Fresh butter is nourishing and relaxing, but it readily becomes sour, and, in general, agrees with few stomachs. Rancid butter is one of the most unwholesome and indigestible of all foods.

Butter of antimony. See *Murias antimonii.*

BUTTER OF CACAO. An oily concrete white matter, of a firmer consistence than suet, obtained from the cacao nut, of which chocolate is made. The method of separating it consists in bruising the cacao and boiling it in water. The greater part of the super-abundant and uncombined oil contained in the nut is by this means liquefied, and rises to the surface, where it swims, and is left to congeal, that it may be the more easily taken off. It is generally mixed with small pieces of the nut, from which it may be purified, by keeping it in fusion without water in a pretty deep vessel, until the several matters have arranged themselves according to their specific gravities. By this treatment it becomes very pure and white.

Butter of cacao is without smell, and has a very mild taste, when fresh; and in all its general properties and habitudes it resembles fat oils, among which it must therefore be classed. It is used as an ingredient in pomatums.

BUTTER-BUR. See *Tussilago petasites.*

BUTTER-FLOWER. See *Ranunculus.*

Butter-milk. The thin and sour milk which is separated from the cream by churning it into butter.

BUTTERWORT. See *Pinguicula.*

BUTUA. See *Cissampelos pariera.*

BUTYRIC ACID. We owe the discovery of this acid to M. Chevreul. Butter, he says, is composed of two fat bodies, analogous to those of hog's lard, of a colouring principle, and a remarkably odorous one, to which it owes the properties that distinguish it from the fats, properly so called. This principle, which he has called butyric acid, forms well-characterized salts with barytes, strontian, lime, the oxides of copper, lead, &c.; 100 parts of it neutralize a quantity of base which contains about 10 of oxygen. M. Chevreul has not explained his method of separating this acid from the other constituents of butter. See *Journ. de Pharmacie*, iii. 80.

BUTY'RUM. See *Butter.*

BUTYRUM ANTIMONY. See *Murias antimonii.*

BUXTON. A village in Derbyshire in which there are warm mineral springs. *Buxtonienses aquæ.* They have been long celebrated for their medicinal properties. With respect to sensible properties, the Buxton water cannot be distinguished from common spring water, when heated to the same temperature. Its temperature, in the gentleman's bath, is invariably 82°. The principal peculiarity in the appearance of this spring, is a large quantity of elastic vapour, that rises and forms bubbles, which pass through the water, and break as soon as they reach the surface. The air of these bubbles was ascertained, by Dr. Pearson, to consist of azotic gas, mixed with a small proportion of atmospheric air. Buxton water is frequently employed both internally and externally: one of which methods often proves beneficial, when the other would be injurious: but, as a bath alone, its virtues may not be superior to those of tepid common water. As the temperature of 82° is several degrees below that of the human body, a slight shock of cold is felt on the first immersion into the bath; but this is almost immediately succeeded by a pleasing glow over the whole system. It is therefore proper for very delicate and irritable habits. The cases which derive most benefit from the *external* use of Buxton waters, are those in which a loss of action, and sometimes of sensation, affects particular limbs, in consequence of long-continued or violent inflammation, or external injury. Hence the chronic rheumatism succeeding the acute, and where the inflammation has been seated in particular limbs, is often wonderfully relieved by this bath. The *internal* use of the water has been found to be of considerable service in symptoms of defective digestion, and derangement of the alimentary organs. A judicious use of this simple remedy will often relieve the heart-burn, flatulency, and sickness; it will increase the appetite, animate the spirits, and improve the health. At first, however, it sometimes occasions a diarrhœa, which is rather salutary than detrimental; but costiveness is a more usual effect, especially in sluggish habits. It also affords great relief when taken internally, in painful disorders of the bladders and kidneys; and has likewise been recommended in cases of gout; but when taken for these complaints, the addition of some aromatic tincture is recommended. In all cases of active inflammation, the use of these waters should be carefully avoided, on account of their supposed heating properties. A full course consists of two glasses, each containing one-third of a pint, before breakfast; which quantity should be repeated between breakfast and dinner. In chronic cases, a long residence on the spot is requisite to ensure the desired effect.

BU'XUS. (From ϖυκαζω, to become hard.) The box-tree. 1. The name of a genus of plants in the Linnæan system. Class, *Monœcia;* Order, *Triandria.*

2. The pharmacopœial name of the box. See *Buxus sempervirens.*

BUXUS SEMPERVIRENS. The systematic name of the *buxus* of the pharmacopœias. The leaves possess a very strong, nauseous, bitter taste, and aperient virtues. They are occasionally exhibited, in form of decoction, among the lower orders of people, in cases of dropsy, and asthma, and worms. As much as will lie upon a shilling, of the common dwarf box, dried and powdered, may be given at bed-time, every night, to an infant.

BY'ARUS. A plexus of blood-vessels in the brain.

BYNG. A Chinese name for green tea.

BYRE'THRUM. (*Beretta*, Ital. or *barette*, Fr. a cap.) *Byrethrus.* An odoriferous cap, filled with cephalic drugs, for the head.

BY'RSA. (Βυρσα, leather.) A leather skin, to spread plaisters upon.

BYSAU'CHEN. (From βυω, to hide, and αυχην, the neck.) Morbid stiffness of the neck.

BYSSOLITE. A massive mineral of an olive green colour, found at the foot of Mount Blanc and near Oisans, in gneiss.

BY'SSUS. (Hebrew.) 1. A woolly kind of moss.

2. The Pudendum muliebre.

3. A kind of fine linen.

BY'THOS. (Βυθος, deep.) An epithet used by Hippocrates for the bottom of the stomach.

BY'ZEN. (From βυω, to rush together.) In a heap; throngingly. Hippocrates uses this word to express the hurry in which the menses flow in an excessive discharge.

C.

C, in the chemical alphabet, means nitre.

CABALI′STICA ARS. (It is derived from the Hebrew word signifying to receive by tradition.) *Cabala; Cabula; Kabala.* The cabalistic art. A term that hath been anciently used, in a very mysterious sense, among divines; and since, some enthusiastic philosophers and chemists transplanted it into medicine, importing by it somewhat magical; but such unmeaning terms are now justly rejected.

Cabalistic art. See *Cabalistica ars.*

CABALLINE. (*Caballinus*; from καϐαλλος, a horse.) Of, or belonging to, a horse; applied to the coarsest aloes, because it is so drastic as to be fit only for horses.

Caballine aloes. See *Aloë.*

CABBAGE. See *Brassica.*

Cabbage tree. See *Geoffroya jamaicensis.*

CACAGO′GA. (From κακκη, excrement, and αγῶ, to expel.) 1. Cathartics.

2. Ointments which, being rubbed on the fundament, procure stools.—*Paulus Ægineta.*

CACA′LIA. (From κακον, bad, and λιαν, exceedingly; because it is mischievous to the soil on which it grows.) *Cacamum.* The herb wild chervil, or wild carraways.

CA′CAMUM. See *Cacalia.*

CA′CAO. See *Theobronia cacoa.*

CACAPHO′NIA. (From κακος, bad, and φωνη, the voice.) Defective articulation.

CACATO′RIA. (From *caco*, to go to stool.) An epithet given by Sylvius to a kind of intermittent fever, attended with copious stools.

CACCIO′NDE. A pill recommended by Baglivi against dysenteries; its basis is catechu.

CACHE′XIA. (From κακος, bad, and ἕξις, a habit.) A bad habit of body, known by a depraved or vitiated state of the solids and fluids.

CACHE′XIÆ. (The plural of *cachexia.*) A class of diseases in Cullen's Nosology, embracing three orders; viz. *Marcores, Intumescentiæ,* and *Impetigines.*

CACHINNA′TIO. (From *cachinno*, to laugh loud.) A tendency to immoderate laughter, as in some hysteric and maniacal affections.

CA′CHLEX. A little stone, or pebble. Galen says, that the cachleces, heated in the fire and quenched in whey, become astringents, and useful in dysenteries.

CACHOLONG. A variety of quartz.

CACHO′RE. A name of catechu.

CA′CHRYS. (Καχρυς: which is used in various senses.) 1. Galen says it sometimes means parched barley.

2. The name of a genus of plants in the Linnæan system. Class, *Pentandria;* Order, *Digynia.*

CACHRYS ODONTALGICA. A plant, the root of which may be substituted for that of the pyrethrum against toothache.

CACHU. See *Acacia catechu.*

CACHU′NDE. A medicine highly celebrated among the Chinese and Indians, made of several aromatic ingredients, perfumes, medicinal earths, and precious stones. They make the whole into a stiff paste, and form out of it several figures, according to their fancy, which are dried for use. These are principally used in the East Indies, but are sometimes brought over to Portugal. In China, the principal persons usually carry a small piece in their mouths, which is a continued cordial, and gives their breath a very sweet smell. It is highly esteemed as a medicine in nervous complaints; and it is reckoned a prolonger of life, and a provocative to venery; the two great intentions of most of the medicines used in the East.

CACHY′MIA. Κακυμια. An imperfect metal, or an immature metalline ore, according to Paracelsus.

CACOALEXITE′RIUM. (From κακος, bad, and αλεξιτηρεω, to preserve.) An antidote to poison or against infectious diseases.

CACOCHO′LIA. (From κακος, and χολη, bile.) A vitiated or unhealthy condition of the bile.

CACOCHY′LIA. (From κακος, bad, and χυλη, the chyle.) Indigestion, or depraved chylification.

CACOCHY′MIA. (From κακος, bad, and χυμος, juice, or humour.) A diseased or depraved state of the humours.

CACOCNE′MUS. (From κακος, bad, and κνημη, the leg.) Having a natural defect in the tibia.

CACOCORE′MA. (From κακος, bad, and κορεω, to purge or cleanse.) A medicine which purges off the vitiated humours.

CACODÆ′MON. (From κακος, bad, and δαιμων, a spirit.) An evil spirit, or genius, which was supposed to preside over the bodies of men, and afflict them with certain disorders. The night-mare.

CACO′DIA. (From κακος, bad, and ωζω, to smell.) A defect in the sense of smelling.

CACOE′THES. (From κακος, ill, and ηθος, a word which, when applied to diseases, signifies a quality, or a disposition.) Hippocrates applied this word to malignant and difficult distempers. Galen, and some others, express by it an incurable ulcer, that is rendered so through the acrimony of the humours flowing to it. Linnæus and Vogel use this term much in the same sense with Galen, and describe the ulcer as superficial, spreading, weeping, and with callous edges.

CACOPA′THIA. (From κακος, bad, and ϖαθος, affection.) An ill affection of the body, or part.

CACOPHO′NIA. (From κακος, bad, and φωνη, the voice.) 1. A defect in the organs of speech.

2. A bad pronunciation.

CACOPRA′GIA. (From κακος, bad, and ϖραττω, to perform.) Diseased viscera.

CACORRY′THMUS. (From κακος, bad, and ρυθμος, order.) A disordered pulse.

CACO′SIS. (From κακος, bad.) A bad disposition of body.

CACOSI′TIA. (From κακος, and σιτιον, food.) An aversion to food, or nausea.

CACOSPHY′XIA. (From κακος, bad, and σφυξις, pulse.) A disorder of the pulse.

CACOSTO′MACHUS. (From κακος, bad, and στομαχος, the stomach.) A bad or disordered stomach; applied also to food which the stomach rejects.

CACO′STOMUS. (From κακος, bad, and στομα, a mouth.) Having a bad formed, or disordered mouth.

CACOTHY′MIA. (From κακος, ill, and θυμος, the mind.) Any vicious disposition of the mind; or a diseased mind.

CACOTRO′PHIA. (From κακος, ill, and τροφη, nutriment.) 1. A vitiated nourishment.

2. A wasting of the body, from want of nutrition.

CA'CTUS. (From κακτος, the Greek name of a plant described by Theophrasta.) The name of a genus of plants in the Linnæan system. Class, *Icosandria;* Order, *Monogynia.* The melon-thistle.

Cactus opuntia. The systematic name of the *opuntia* of the pharmacopœias. The prickly leaves of this plant abound with a mucilaginous matter, which is esteemed in its native countries an emollient, in the form of poultice.

CACU'BALUS. (From κακος, evil, and βαλλω, to cast out; so named because it was thought to be efficacious in expelling poisons.) See *Cucubalus bacciforum.*

Ca'cule. The Arabian for cardamoms.

CACU'MEN. (*Cacumen minis.* neut.) The top or point.

CADA'VER. (*Cadaver veris.* neut.; from *cado*, to fall: because the body, when deprived of life, falls to the ground.) A carcase, or body deprived of life.

CA'DMIA. (Hebrew.) The lapis calaminaris. See *Zinc.*

Cadmia metallica. A name given, by the Germans, to cobalt.

CADMIUM. "A new metal, first discovered by M. Stromeyer, in the autumn of 1817, in some carbonate of zinc which he was examining in Hanover. It has been since found in the Derbyshire silicates of zinc.

The following is Dr. Wollaston's process for procuring cadmium. From the solution of the salt of zinc supposed to contain cadmium, precipitate all the other metallic impurities by iron; filter and immerse a cylinder of zinc into the clear solution. If cadmium be present, it will be thrown down in the metallic state, and when redissolved in muriatic acid, will exhibit its peculiar character on the application of the proper tests.

M. Stromeyer's process consists in dissolving the substance which contains cadmium in sulphuric acid, and passing through the acidulous solution a current of sulphuretted hydrogen gas. He washes this precipitate, dissolves it in concentrated muriatic acid, and expels the excess of acid by evaporation. The residue is then dissolved in water, and precipitated by carbonate of ammonia, of which an excess is added, to redissolve the zinc and the copper, that may have been precipitated by the sulphuretted hydrogen gas. The carbonate of cadmium being well washed, is heated, to drive off the carbonic acid, and the remaining oxide is reduced by mixing it with lamp-black, and exposing it to a moderate red heat in a glass or earthen retort.

The colour of cadmium is a fine white, with a slight shade of bluish-grey, approaching much to that of tin; which metal it resembles in lustre and susceptibility of polish. Its texture is compact, and its fracture hackly. It crystallises easily in octohedrons, and presents on its surface, when cooling, the appearance of leaves of fern. It is flexible, and yields readily to the knife. It is harder and more tenacious than tin; and, like it, stains paper, or the fingers. It is ductile and malleable, but when long hammered, it scales off in different places. Its sp. grav. before hammering, is 8.6040; and when hammered, it is 8.6944. It melts, and is volatilised under a red heat. Its vapour, which has no smell, may be condensed in drops like mercury, which, on congealing, present distinct traces of crystallisation.

Cadmium is as little altered by exposure to the air as tin. When heated in the open air, it burns like that metal, passing into a smoke, which falls and forms a very fixed oxyde, of a brownish-yellow colour. Nitric acid readily dissolves it cold; dilute sulphuric, muriatic, and even acetic acids, act feebly on it with the disengagement of hydrogen. The solutions are colourless, and are not precipitated by water.

Cadmium forms a single oxide, in which 100 parts of the metal are combined with 14.352 of oxygen. The prime equivalent of cadmium deduced from this compound seems to be very nearly 7, and that of the oxide 8. This oxide varies in its appearance according to circumstances, from a brownish-yellow to a dark brown, and even a blackish colour. With charcoal it is reduced with rapidity below a red heat. It gives a transparent colourless glass bead with borax. It is insoluble in water, but in some circumstances forms a white hydrate, which speedily attracts carbonic acid from the air, and gives out its water when exposed to heat."—*Ure's Chem. Dict.*

CADOGAN, William, graduated at Oxford in 1755. Five years before, he had published a small treatise on the management of children, which was very much approved. In 1764 his "Dissertation on the Gout and all Chronic Diseases" appeared, which attracted considerable attention, being written in a popular style. He referred the gout principally to indolence, vexation, and intemperance; and his plan of treatment is generally judicious. He was a fellow of the London College of Physicians, and died in 1797, at an advanced age.

Cadtchu. See *Acacia catechu.*

CADU'CA. (From *cado*, to fall down.) See *Decidua.*

Caduci. The name of a class in Linnæus's Methodus calycina.

CADU'CUS. (From *cado*, to fall.) 1. *In Botany,* The falling off before the unfolding of the flower or leaf; as the *perianthium* of Papaver, the *stipulæ* of *Prunus avium.* This term is expressive of the shortest period of duration, and has different acceptations, according to the different parts of the plant to which it is applied. A calyx is said to be caducous, which drops at the first opening of the petals, or even before as in the poppy. Petals are caducous, which are scarcely unfolded before they fall off, as in *Thalictrum;* and such leaves as fall off before the end of summer, have obtained this denomination. See *Deciduus,* and *Parasiticus.*

2. The epilepsy or falling sickness is called *morbus caducus.*

CÆ'CITAS. (From *cæcus*, blind.) Blindness. See *Caligo,* and *Amaurosis.*

CÆ'CUM. (From *cæcus*, blind: so called from its being perforated at one end only.) The cæcum, or blind gut. The first portion of the large intestines, placed in the right iliac region, about four fingers' breadth in length. It is in this intestine that the ileum terminates by a valve, called the valve of the cæcum. The *appendicula cæci vermiformis* is also attached to it. See *Intestines.*

CÆ'LIUS Aurelianus, is supposed to have been born at Sicca, in Africa, and is referred by Le Clerc to the fifteenth century, from the harshness of his style. He has left a Latin translation of the writings of Soranus, with additional observations, partly collected from others, partly from his own experience. The work is in eight books, three on acute, the rest on chronic disorders. He treats of several diseases not mentioned by any earlier writers, and has some observations in surgery peculiar to himself; he appears, too, generally correct in his remarks on the opinions of others.

Cæ'ros. Καιρός. Hippocrates, by this word, means the opportunity or moment in which whatever is to be effected should be done.

CÆSALPINI'A. (Named in honour of Cæsalpinus, chief physician to Pope Clement VIII.) The name of a genus of plants in the Linnæan system. Class, *Decandria*; Order, *Monogynia*.

Cæsalpinia crista. The systematic name of the tree that affords the Brazil wood. It is of the growth of the Brazils in South America, and also of the Isle of France, Japan and elsewhere. It is chiefly used as a red dye.

CÆSALPI'NUS, Andrew, was born in Tuscany in 1519. He graduated at Pisa, and became professor in anatomy and medicine there; and was afterwards made physician to Pope Clement VIII. He died in 1603. His works are numerous, and evince much genius and learning. In 1571, he published a work, defending the philosophy of Aristotle against the doctrines of Galen, from some passages in which he appears to have approached very near to a knowledge of the circulation of the blood; having explained the use of the valves of the heart, and pointed out the course which these compelled the blood to take on both sides during the contraction and dilatation of that organ. In a treatise "De Plantis," he justly compared the seeds to the eggs of animals; and formed an arrangement of them according to the parts of fructification. On medical subjects also he offered many judicious remarks.

CÆ'SARES. *Cæsones.* Children who are brought into the world as Julius Cæsar is said to have been. See *Cæsarian operation.*

CÆSA'RIAN OPERATION. (So called, because Julius Cæsar is said to have been extracted in this manner.) *Hysterotomia. Hysterotomatocia.* The operation for extracting the fœtus from the uterus, by dividing the integuments of the abdomen and the uterus.

There are three cases in which this operation may be necessary.—1. When the fœtus is perceived to be alive, and the mother dies, either in labour or in the last two months. 2. When the fœtus is dead, but cannot be delivered in the usual way, from the deformity of the mother, or the disproportionate size of the child. 3. When both the mother and the child are living, but delivery cannot take place, from the same causes as in the second instance. Both the mother and the child, if accounts can be credited, have often lived after the Cæsarian operation, and the mother even borne children afterwards. Heister gives a relation of such success, in his Institutes of Surgery; and there are some others. In England, the Cæsarian operation has almost always failed. Mr. James Barlow, of Chorley, Lancashire, succeeded, however, in taking a fœtus out of the uterus by this bold proceeding, and the mother was perfectly restored to health.

Cæ'tchu. See *Acacia catechu.*

Caf; *Cafa; Caffa.* Names given by the Arabians to camphire.

CAFFEIN. The name of a bitter principle procured from coffee by Chenevix, by adding muriate of tin to an infusion of unroasted coffee. From this he obtained a precipitate, which he washed and decomposed by sulphuretted hydrogen. The supernatant liquid contained this principle, which occasioned a green precipitate in concentrated solutions of iron. When the liquid was evaporated to dryness, it was yellow and transparent, like horn. It did not attract moisture from the air, but was soluble in water and alkohol. The solution had a pleasant bitter taste, and assumed with alkalies a garnet-red colour. It is almost as delicate a test of iron as infusion of galls is; yet gelatine occasions no precipitate with it.

Caga'strum. A barbarous term used by Paracelsus, to express the morbific matter which generates diseases.

Caitchu. See *Acacia catechu.*

CAIUS, John, was born at Norwich in 1510. After studying at Cambridge, and in different parts of Italy, and distinguishing himself by his interpretations of Hippocrates, Galen, and other ancient authors, he graduated at Bologna. In 1544, he returned to this country, and for some time read lectures in anatomy to the corporation of surgeons in London. He afterwards practised at Shrewsbury, having been admitted a fellow of the College of Physicians; and published a popular account of the memorable sweating sickness, which prevailed in 1551, subsequently reprinted, much improved, in Latin. He was made physician to Edward VI., to Mary and to Elizabeth. On the death of Linacre, he was chosen President of the College of Physicians, and during the seven years, for which he held that office, performed many important services. He was also a signal benefactor to Gonvil Hall, where he studied at Cambridge, having obtained permission to erect it into a college, considerably enlarging the building, and assigning provision for three fellows and twenty scholars. He was chosen master on the completion of the improvements, and retained that office till near the period of his death, which happened in 1573. He published a dissertation "De Canibus Britanicis," which Mr. Pennant has entirely followed in his British Zoology, and some other learned works besides those already mentioned.

Ca'jan. See *Phaseolus creticus.*

Ca'jeput oil. See *Melaleuca.*

Cala'ba. See *Catophyllum inophyllum.*

Calagua'læ radix. *Calaguelæ radix.* The root so called is knotty, and somewhat like that of the polypody tribe. It has been exhibited internally at Rome, with success, in dropsy; and it is said to be efficacious in pleurisy, contusions, abscesses, &c. It was first used in America, where it is obtained; and Italian physicians have since written concerning it, in terms of approbation.

Calama'corus. Indian reed.

CALAMAGRO'STIS. (From καλαμος, a reed, and αγρωςις, a sort of grass.) Reed grass. *Gramen Arundinacum.* The *Arundo calamagrostis* of Linnæus; the root of which is said to be diuretic and emmenagogue.

CALAMARIÆ. (From *calamus*, a reed.) The name of an order of Linnæus's fragments of a natural method, which embraces the reed-plants.

Cala'mbac. An Indian name for agalochum. See *Lignum Aloes.*

Calame'don. (From καλαμος, a reed.) A sort of fracture which runs along the bone, in a straight line, like a reed, but is lunated in the extremity.

CA'LAMINA. See *Calamine.*

Calamina præparata. Prepared calamine. Burn the calamine, and reduce it to powder; then let it be brought into the state of a very fine powder, in the same manner that chalk is directed to be prepared. See *Calamine.*

CA'LAMINE. (*Calamina*; from *calamus*, a reed: so called from its reed-like appearance.) *Cadmia; Cathmia; Cadmia lapidosa ærosa; Cadmia fossilis; Calamina; Lapis calaminaris.* A native carbonate of zinc. A mineral, containing oxide of zinc and carbonic acid, united with a portion of iron, and sometimes other substances. It is very heavy, moderately hard and brittle, of a grey, yellowish, red, or blackish brown; found in quarries of considerable extent, in several parts of Europe, and particularly in this country, in Derbyshire, Gloucestershire, Nottinghamshire, and Somersetshire; as also in Wales. The calamine of England is by the best judges, allowed to be superior in quality to that of most other countries. It seldom lies very deep, being chiefly found in clayey grounds, near the surface. In some places it is mixed with lead ores. This mineral is an article in the materia medica; but, before it comes to the shops, it is usually roasted, or calcined, to separate some arsenical or sulphureous particles which, in its crude state, it is supposed to contain, and in order to render it more easily reducible into a fine powder. In this state, it is employed in collyria, for weak eyes, for promoting the cicatrisation of ulcers, and healing excoriations of the skin. It is the basis of an officinal cerate, called Ceratum calaminæ by the London College, formerly called ceratum lapidis caliminaris, ceratum epuloticum; and ceratum carbonatis zinci impuri by the Edinburgh College. These compositions form the cerate which Turner strongly recommends for healing ulcerations and excoriations, and which have been popularly distinguished by his name. The collyria in which the prepared calamine has been employed, have consisted simply of that substance added to rose-water, or elder-flower water.

CALAMINT. See *Melissa calamintha.*

Calamint, mountain. See *Melissa grandiflora.*

CALAMI'NTHA. (From καλος, beautiful, or καλαμος, a reed, and μινθη, mint.) Common calamint. See *Melissa.*

Calamintha anglica. See *Melissa nepeta.*

Calamintha humilior. The ground-ivy. See *Glecoma hederacea.*

Calamintha magno flore. See *Melissa grandiflora.*

Calamintha montana. See *Melissa Calamintha.*

CA'LAMUS. (From *Kalam*, an Arabian word.) 1. A general name denoting the stalk of any plant.

2. The name of a genus of plants in the Linnæan system. Class, *Hexandria;* Order, *Monogynia.*

Calamus aromaticus. See *Acorus calamus.*

Calamus aromaticus asiaticus. See *Acorus calamus.*

Calamus odoratus. The sweet-scented rush. See *Acorus calamus.*

Calamus rotang. The systematic name of the plant from which we obtain the Dragon's blood. *Cinnabaris græcorum Draconthæma; Asegen; Asegon.* Dragon's blood. The red resinous juice which is obtained by wounding the bark of the *Calamus rotang;—caudice densissime aculeato, aculeis erectis, spadice erecto.* The *Petrocarpus draco* and *Dracæna draco,* also afford this resin. It is chiefly obtained from the Molucca islands, Java, and other parts of the East Indies. It is generally much adulterated, and varied in goodness and purity. The best kind is of a dark red colour, which, when powdered, changes to crimson: it is insoluble in water, but soluble in a great measure in alcohol; it readily melts and catches flame, has no smell, but to the taste discovers some degree of warmth and pungency. The ancient Greeks were well acquainted with the adstringent power of this drug; in which character it has since been much employed in hæmorrhages, and in alvine fluxes. At present, however, it is not used internally, being superseded by more certain and effectual remedies of this numerous class.

Calamus scriptorius. A furrow or kind of canal at the bottom of the fourth ventricle of the brain, so called from its resemblance to a writing pen.

Calamus vulgaris. See *Acorus calamus.*

CALATHIANA. (From καλαθος, a twig basket; so called from the shape of its flowers.) The herb marsh-gentian. See *Gentiana pneumonanthe.*

Calei'anum. The name of a plaster in Myrepsus.

Calca'dinum. Vitriol.

Calca'dis. An Arabian name for white vitriol and alkali.

CALCA'NEUM. (From *calx*, the heel.) *Calcar pterna; Os calcis.* The largest bone of the tarsus, which forms the heel. It is situated posteriorly under the astragalus, is very regular, and divided into a body and processes. It has a large *tuberosity* or knob, projecting behind to form the heel. A *sinuous cavity*, as its fore-part, which, in the fresh subject, is filled with fat, and gives origin to several ligaments. Two *prominences*, at the inner and fore-part of the bone, with a pit between them, for the articulation of the under and fore-part of the astragalus. A *depression*, in the external surface of the bone near its fore-part, where the tendon of the peronæus longus runs. A large *cavity*, at the inner side of the bone, for lodging the long flexors of the toes, together with the vessels and nerves of the sole. There are two *prominences*, at the under and back part of this bone, that give origin to the aponeurosis, and several muscles of the sole. The anterior surface of the os calcis is concave, for its articulation with the os cuboides, and it is articulated to the astragalus by ligaments.

Calcan'thum. (From χαλκος, brass, and ανθος, a flower; i. e. flowers of brass.) *Calcanthos.* Copperas; Vitriol.

CALCAR. (*Calcar, aris.* n. From *calx*, the heel; also from *caleo*, to heat.) 1. The heel-bone.

2. The furnace of a laboratory.

3. A spur. In botany, applied to a part of the ringent and personate corolla of plants. It is a tube forming an obtuse or acute sac, at the side of the receptacle. It is of rare occurrence.

CALCARATUS. Spurred; applied to the corols and nectaries of plants; as *Calcarata corolla, Nectarium calcaratum;* as in *Aquilegia* and *Antirrhinum linaria.*

CALCAREOUS. (*Calcarius;* from *calx*, lime.) That which partakes somewhat of the nature and qualities of *calx.*

Calcareous earth. See *Calx and Lime.*

Calcareous spar. Crystallised carbonate of lime, which occurs in more than 600 different forms. It is found in veins in all rocks from granite to alluvial strata. The rarest and most beautiful crystals are found in Derbyshire, but it exists in every part of the world.

Calca'ris flos. The larkspur.

CALCA'RIUS. See *Calcareous.*

Calcarius lapis. Limestone.

Ca'lcatar. A name of vitriol.

Ca'lcaton. White arsenic. Troches of arsenic. An obsolete term.

Calcatri'ppa. See *Ajuga pyramidalis.*

CALCEDONY. A mineral, so called from Calcedon, in Asia Minor, where it was found in ancient times. There are several sub-species, common calcedony, heliotrope, chrysoprase, plasma, onyx, sand, and sardonyx.

Common calcedony occurs of various colours; it is regarded as pure silica with a little water. Very fine stalactitical specimens have been found in Cornwall and Scotland.

Calce'na. *Calcenonius; Calcetus.* Paracelsus uses these words to express the tartarous matter in the blood; or that the blood is impregnated with tartarous principles.

Ca'lceum equinum. (From *calceus*, a shoe, and *equus*, a horse; so called from the figure of its leaf.) The herb colt's-foot. See *Tussilago farfara.*

Calchantrum. Pliny's name for copperas.

Calchi'theos. (From καλχιον, purple.) Verdigris.

Calchoi'des. (From χαλιξ, a chalk-stone, and ειδος, form.) An obsolete name of the cuneiform bones.

Calcidi'cium. The name of a medicine in which arsenic is an ingredient.

CALCI'FRAGA. (From *calx*, a stone, and *frango*, to break; so named from its supposed property of breaking the human calculus.) Breakstone. In *Scribonius Largus*, it means, the herb spleenwort, or *scolopendrium;* others mean by it the *pimpinella saxafraga* of Linnæus.

CALCINA'TION. Oxydation. The fixed residues of such matters as have undergone combustion are called cinders, in common language, and calces, but now more commonly oxides, by chemists; and the operation, when considered with regard to these residues, is termed calcination. In this general way, it has likewise been applied to bodies not really combustible, but only deprived of some of their principles by heat. Thus we hear of the calcination of chalk, to convert it into lime by driving off its carbonic acid and water; of gypsum, or plaster-stone, of alum, of borax, and other saline bodies, by which they are deprived of their water of crystallisation; of bones which lose their volatile parts by this treatment, and of various other bodies.

CALCINA'TUS. Calcined.

Calcinatum majus. Whatsoever is dulcified by the chemical art, which was not so by nature; such as dulcified mercury, lead, and the like substances, which are very speedily consolidated.

Calcinatum majus Poterii. Mercury dissolved in aqua fortis, and precipitated with salt water. Poterius used it in the cure of ulcers.

Calcinatum minus. Any thing which is sweet by nature, and speedily cures, as sugar, manna, tamarinds, &c.

Calcino'nia. See *Calcena.*

Ca'lcis aqua. See *Calcis liquor.*

Ca'lcis liquor. Solution of lime, formerly called *aqua calcis.* Lime-water. Take of lime, half a pound; boiling distilled water, twelve pints. Pour the water upon the lime, and stir them together; next cover the vessel immediately, and let it stand for three hours; then keep the solution upon the remaining lime in stopped glass bottles, and pour off the clear liquor when it is wanted for use.

Lime is soluble in about 450 times its weight of water, or little more than one grain in one fluid-ounce. It is given internally, in doses of two ounces and upwards, in cardialgia, spasms, diarrhœa, &c. and in proportionate doses in convulsions of children arising from acidity, or ulcerated intestines, intermittent fevers, &c. Externally it is applied to burns and ulcers.

Calcis murias. *Calx solita; Sal ammoniacus fixus.* Muriate of lime. Take of the salt remaining after the sublimation of subcarbonate of ammonia two pounds, water a pint; mix and filter through paper. Evaporate the salt to dryness: and preserve it in a closely-stopped vessel. This preparation is exhibited with the same views as the muriate of barytes. It possesses deobstruent, diuretic, and cathartic virtues, and is much used by the celebrated Fourcroy against scrophula, and other analogous diseases. Six, twelve, and twenty grains are given to children three times a day, and a drachm to adults.

Calcis muriatis liquor. Take of muriate of lime two ounces, distilled water three fluid-ounces; dissolve the salt in the water, and filter it through paper.

Ca'lcis os. See *Calcaneum.*

Calcis vivi flores. The pellicle on the surface of lime water.

Calcita'ri. Alkaline salt.

Calcite'a. Vitriol.

Calciteo'sa. Litharge.

Ca'lcithos. Verdigris.

CALCITRA'PA. (An old botanical term of similar meaning to *tribulus*, compounded of *calco*, to tread or kick, and τρεπω, to turn, because the caltrops are continually kicked over if they fail of their intended mischief. See *Trapa.*) See *Centaurea calcitrapa.*

Calcitrapa officinalis. See *Centaurea solstitialis.*

Calcitre'a. Vitriol.

CALCIUM. The metallic basis of lime. Sir H. Davy, the discoverer of this metal, procured it by the process which he used for obtaining *barium.* It was in such small quantities, that little could be said concerning its nature. It appeared brighter and whiter than either barium or strontium; and burned when gently heated, producing dry lime.

There is only one known combination of calcium and oxygen, which is the important substance called lime. The nature of this substance is proved by the phenomena of the combustion of calcium; the metal changing into the earth with the absorption of oxygen gas. When the amalgam of calcium is thrown into water, hydrogen gas is disengaged, and the water becomes a solution of lime. From the quantity of hydrogen evolved, compared with the quantity of lime formed in experiments of this kind, M. Berzelius endeavoured to ascertain the proportion of oxygen in lime. The nature of lime may also be proved by analysis. When potassium in vapour is sent through the earth ignited to whiteness, the potassium was found by Sir H. Davy to become potassa, while a dark grey substance of metallic splendour, which is calcium, either wholly or partially deprived of oxygen, is found imbedded in the potassa, for it effervesces violently, and forms a solution of lime by the action of water.

Ca'lcotar. Vitriol.

CALCSINTER. Stalactitical carbonate of lime, which is continually forming by the infiltration of carbonated lime water through the crevices of the roofs of caverns. The irregular masses on the bottoms of caves have been called *stalagmites.*

CALCTUFF. An alluvial formation of carbonate of lime, probably deposited from calcareous springs of a yellowish dull grey colour containing impressions of vegetable matter.

CALCULI'FRAGUS. (From *calculus*, a stone, and *frango*, to break.) Stone-breaker, having the power to break stone in the human body. 1. A synonym of lithontriptic. See *Lithontriptic.* 2. The scolopendrium, and pimpernel. See *Calcifraga.*

CA'LCULUS. (Diminutive of *calx*, a limestone.) *Calculus humanus; Bezoar microcos-*

micum. Gravel; Stone. In English we understand by *gravel*, small sand-like concretions, or stones, which pass from the kidneys through the ureters in a few days; and by *stone*, a calculous concretion in the kidneys, or bladder, of too large a size to pass, without great difficulty. Similar concretions are found occasionally in other cavities, or passages. When a disposition to form minute calculi or gravel exists, we often find nephritic paroxysms, as they are called, (see *Nephritis*,) which consist of pain in the back, shooting down through the pelvis to the thighs; sometimes a numbness in one leg, and a retraction of either testicle in men, symptoms arising from the irritation of a stone passing through the ureters, as these cross the spermatic cord, on the nerves passing to the lower extremities. These pains, often violent, are terminated by the painful discharge of small stones through the urethra, and the patient is for a time easy. What, however, is meant by the stone is a more serious and violent disease. It is singular that these discharges of small gravel do not usually terminate in stone. Many have experienced them during a long life, without any more serious inconvenience: while the latter is a disease chiefly of the young, and depending on circumstances not easily explained. If the stone attacks persons more advanced in age, it is often the consequence of paroxysms of gout, long protracted, and terminating imperfectly.

When once a stone has acquired a moderate size, it usually occasions the following symptoms:—frequent inclination to make water, excessive pain in voiding it drop by drop, and sometimes a sudden stoppage of it, if discharged in a stream; after making water, great torture in the glans penis, which lasts one, two, or three minutes; and, in most constitutions, the violent straining makes the rectum contract and expel its excrements; or, if it be empty, occasions a tenesmus, which is sometimes accompanied with a prolapsus ani. The urine is often tinctured with blood, from a rupture of the vessels, and sometimes pure blood itself is discharged. Sometimes the urine is very clear, but frequently there are great quantities of slimy sediment deposited at the bottom of it, which is only a preternatural separation of the mucilage of the bladder, but has often been mistaken for pus. The stone is a disease to which both sexes and all ages are liable; and calculi have even been found in the bladders of very young children, nay of infants only six months old.

Women seem less subject to this complaint than men, either owing to constitutional causes, or to the capaciousness, shortness, and straightness of their urethræ, allowing the calculi to be discharged while small, together with the urine.

The Seat and Physical Properties of Urinary Calculi.

Calculi are found in different parts of the urinary system, in the pelvis of the kidney, in the ureters, in the bladder and urethra; but as they, for the most part, originate in the kidney, the calculi renales make the nucleus of the greatest number of urinary stones. The *calculi renales*, differ greatly with respect to their external qualities; for the most part, however, they consist of small, concrete, roundish, smooth, glossy, and crystalline bodies, of a red-yellow colour, like that of wood, and so hard as to admit of polishing. On account of their minuteness, they easily pass through the urinary passages in form of gravel, which being sometimes of a rough surface, cause several complaints on their passage. But in some instances they are of too great a size to be able to pass along the ureters; in which case they increase in the kidneys, sometimes to a great size. Calculi renales of this kind are generally of a brown, dark red, or black colour, and surrounded with several strata of coagulated blood and pus; they have also been observed of a yellow, reddish, and lighter colour; and some consisting of an homogeneous stony mass, but white or grey calculi renales are very rarely to be met with. Among the great number that were examined, one or two only were found of a grey or blackish colour, and of a composition similar to those which generally bear the name of mulberry-like stones.

The stones in the ureters, which, on passing into the ureters, are prevented by their size from descending into the bladder, frequently increase very much: they, however, rarely occur; their colour is white, and they consist of phosphate of lime.

The stones in the bladder are the most frequent urinary concrements that have been principally examined; they draw their first origin from the kidneys, whence they descend into the bladder, where they increase; or they immediately originate and increase in the bladder; or they arise from a foreign body that by chance has got into the bladder, which not unfrequently happens, particularly in the female sex. Concretions of this kind differ greatly in their respective physical qualities and external form, which, however, is generally spherical, oval, or compressed on both sides; and sometimes, when there are several stones in the bladder, they have a polyhedrous or cubical form; their extremities are frequently pointed or roundish, but they are very seldom found cylindrical, and more rarely with cylindrical ends.

There is a great variety in the size of the calculi, and likewise in their colour, which is materially different, according to their respective nature and composition. They occur, 1. of a yellowish colour, approaching nearly to red, or brown; such stones consist of lithic acid. 2. Grey, or more or less white; these stones always contain phosphates of earths. 3. Dark grey, or blackish; stones of this colour have oxalates of earths. Many stones show brown or grey spots, on a yellow or white ground, generally raised on the surface, and consisting of oxalate of lime, which is enclosed in lithic acid, when the ground-colour of the stone is of a wood colour, or in phosphate of lime, when it is white. These spots are, in general, only to be observed in the middle of the stone, or at one of its extremities.

All that is here stated, is the result of observations on more than 600 calculi; and different other colours that are said to have been observed, either arise from heterogeneous substances, or are merely variations of the above colours. Their surface is smooth and polished in some; in others, only smooth; and in others uneven, and covered with rough or smooth corpuscles, which are always of a yellow colour; in some, the surface is partly smooth and partly rough. The white ones are frequently even and smooth, half transparent, and covered with shining crystals, that generally indicate phosphate of ammonia, with magnesia; or they are faint, and consist of minute grains; or rough, in which case they consist of phosphate of lime. The brown and dark grey stones are, from their similarity to mulberries, called mulberry-stones, and being frequently very rugged, they cause the most pain of all.

On examining the specific weight of urinary calculi in more than 500 specimens, it was found to be, in the lightest, as 1213.1000, in the heaviest, as 1976.1000. Their smell is partly strong, like urine or ammonia, partly insipid, and terreous; especially the white ones, which are like sawed ivory, or rasped bone.

The internal texture of calculi is but seldom guessed from their external appearance, particularly when they exceed the size of a pigeon's egg. On breaking them, they generally separate into two or three strata, more or less thick and even, which prove that they are formed by different precipitations, at different times. In the middle, a nucleus is generally seen, of the same mass as the rest. When the place they are broken at is finely streaked, and of a yellow or reddish colour, the lithic acid predominates; but when they are half transparent, luminous like spar, they have ammoniacal phosphate of magnesia in them, and phosphate of lime, and then they are brittle and friable; but when they are so hard as to resist the instrument, of a smooth surface, and a smell like ivory, they contain oxalate of lime. It frequently happens, that the exterior stratum consists of white phosphate of earth, while the nucleus is yellow lithic acid, or oxalate of lime, covered sometimes with a yellow stratum of lithic acid, in which case the nucleus appears radiant; but when it consists of lithic acid, and is covered with white phosphate of earth, it is roundish, oval, and somewhat crooked. These concretions have very seldom three strata; namely, on the outside a phosphate, towards the inside lithic acid, and quite withinside an oxalate of lime; but still rarer these substances occur in more strata, or in another order, as before-mentioned.

Stones of the urethra are seldom generated in the urethra itself; however, there are instances of their having been formed in the fossa navicularis, by means of foreign bodies that have got into the urethra. We also very frequently observe stony concrements deposited between the glans and prepuce. All the concretions produced in the inside and outside the urethra consist of phosphate of earths, which are easily precipitated from the urine. There are likewise stones in the urethra which have come out of the bladder, having been produced there, or in the kidneys; and they generally possess the properties of stones of the kidneys.

The different constituents of Urinary Calculi.

"If we except Scheele's original observation concerning the uric or lithic acid, all the discoveries relating to urinary concretions are due to Dr. Wollaston; discoveries so curious and important, as alone are sufficient to entitle him to the admiration and gratitude of mankind. They have been fully verified by the subsequent researches of Fourcroy, Vauquelin, and Brande, Drs. Henry, Marcet, and Prout. Dr. Marcet, in his late valuable essay on the chemical history and medical treatment of calculous disorders, arranges the concretions into nine species.

1. The lithic acid calculus.
2. The ammonia-magnesian phosphate calculus.
3. The bone earth calculus, or phosphate of lime.
4. The fusible calculus, a mixture of the 2d and 3d species.
5. The mulberry calculus, or oxalate of lime.
6. The cystic calculus; cystic oxide of Dr. Wollaston.
7. The alternating calculus, composed of alternate layers of different species.
8. The compound calculus, whose ingredients are so intimately mixed, as to be separable only by chemical analysis.
9. Calculus from the prostate gland, which, by Dr. Wollaston's researches, is proved to be phosphate of lime, not distinctly stratified, and tinged by the secretion of the prostate gland.

To the above Dr. Marcet has added two new sub-species. The first seems to have some resemblance to the cystic oxide, but it possesses also some marks of distinction. It forms a bright lemon yellow residuum on evaporating its nitric acid solution, and is composed of laminæ. But the cystic oxide is not laminated, and it leaves a white residuum from the nitric acid solution. Though they are both soluble in acids as well as alkalies, yet the oxide is more so in acids than the new calculus, which has been called by Dr. Marcet, from its yellow residuum, *xanthic* oxide. Dr. Marcet's other new calculus was found to possess the properties of the fibrin of the blood, of which it seems to be a deposite. He terms it *fibrinous* calculus.

Species 1. *Uric acid calculi.* Dr. Henry says, in his instructive paper on urinary and other morbid concretions, read before the Medical Society of London, March 2, 1819, that it has never yet occurred to him to examine calculi composed of this acid in a state of absolute purity. They contain about 9-10ths of the pure acid, along with urea, and an animal matter which is not gelatin, but of an albuminous nature. This must not, however, be regarded as a cement. The calculus is aggregated by the cohesive attraction of the lithic acid itself. The colour of lithic acid calculi is yellowish or reddish-brown, resembling the appearance of wood. They have commonly a smooth polished surface, a lamellar or radiated structure, and consist of fine particles well compacted. Their sp. gravity varies from 1.3 to 1.8. They dissolve in alkaline lixivia, without evolving an ammoniacal odour, and exhale the smell of horn before the blowpipe. The relative frequency of lithic acid calculi will be seen from the following statement. Of 150 examined by Mr. Brande, 16 were composed wholly of this acid, and almost all contained more or less of it. Fourcroy and Vauquelin found it in the greater number of 500 which they analysed. All those examined by Scheele consisted of it alone; and 300 analysed by Dr. Pearson, contained it in greater or smaller proportion. According to Dr. Henry's experience, it constitutes 10 urinary concretions out of 26, exclusive of the alternating calculi. And Mr. Brande lately states, that out of 58 cases of *kidney* calculi, 51 were lithic acid, 6 oxalic, and 1 cystic.

Species 2. *Ammonia-magnesian phosphate.* This calculus is white like chalk, is friable between the fingers, is often covered with dog-tooth crystals, and contains semi-crystalline layers. It is *insoluble* in alkalies, but soluble in nitric, muriatic, and acetic acids. According to Dr. Henry, the earthy phosphates, comprehending the 2d and 3d species, were to the whole number of concretions, in the ratio of 10 to 85. Mr. Brande justly observes, in the 16th number of his Journal, that the urine has at all times a tendency to deposit the triple phosphate upon any body over which it passes. Hence drains by which urine is carried off, are often incrusted with its regular crystals; and in cases where extraneous bodies have got into the bladder, they have often in a very short time become considerably enlarged by deposition of the same substance. When this calculus, or those incrusted with its semicrystalline particles, are strongly heated before the blowpipe, ammonia is evolved, and an imperfect fusion takes place. When a little of the calcareous phosphate is present, however, the concretion readily fuses. Calculi composed *entirely* of the ammonia-magnesian phosphate are very rare. Mr. Brande has seen only two. They were crystallised upon the surface, and their fracture was somewhat foliated. In its pure state, it is even rare as an incrustation. The powder of the ammonia-phosphate calculus has a brilliant white colour, a faint sweetish taste, and is somewhat soluble in water. Fourcroy and Vauquelin suppose the above deposits to result from incipient putrefaction of urine in the bladder. It is certain that the triple phosphate is copiously precipitated from urine in such circumstances out of the body.

Species 3. The *bone earth calculus.* Its surface, according to Dr. Wollaston, is generally pale brown, smooth, and when sawed through it appears of a laminated texture, easily separable into concentric crusts. Sometimes, also, each lamina is striated in a direction perpendicular to the surface, as from an assemblage of crystalline needles. It is difficult to fuse this calculus by the blowpipe, but it dissolves readily in dilute muriatic acid, from which it is precipitable by ammonia. This species, as described by Fourcroy and Vauquelin, was white, without lustre, friable, staining the hands, paper, and cloth. It had much of a chalky appearance, and broke under the forceps, and was intimately mixed with a gelatinous matter, which is left in a membraneous form, when the earthy salt is withdrawn by dilute muriatic acid. Dr. Henry says, that he has never been able to recognise a calculus of pure phosphate of lime in any of the collections which he has examined; nor did he ever find the preceding species in a pure state, though a calculus in Mr. White's collection contained more than 90 per cent. of ammonia-magnesian phosphate.

Species 4. The *fusible calculus.* This is a very friable concretion, of a white colour, resembling chalk in appearance and texture; it often breaks into layers, and exhibits a glittering appearance internally, from intermixture of the crystals of triple phosphate. Sp. grav. from 1.14 to 1.47. Soluble in dilute muriatic and nitric acids, but not in alkaline lixivia. The nucleus is generally lithic acid. In 4 instances only out of 187, did Dr. Henry find the calculus composed throughout of the earthy phosphates. The analysis of fusible calculus is easily performed by distilled vinegar, which at a gentle heat dissolves the ammonia-magnesian phosphate, but not the phosphate of lime; the latter may be taken up by dilute muriatic acid. The lithic acid present will remain, and may be recognised by its solubility in the water of pure potassa or soda. Or the lithic acid may, in the first instance, be removed by the alkali, which expels the ammonia, and leaves the phosphate of magnesia and lime.

Species 5. The *mulberry calculus.* Its surface is rough and tuberculated; colour deep reddish-brown. Sometimes it is pale brown, of a crystalline texture, and covered with flat octohedral crystals. This calculus has commonly the density and hardness of ivory, a sp. grav. from 1.4 to 1.98, and exhales the odour of semen when sawed. A moderate red heat converts it into carbonate of lime. It does not dissolve in alkaline lixivia, but slowly and with difficulty in acids. When the oxalate of lime is voided directly after leaving the kidney, it is of a greyish-brown colour, composed of small cohering spherules, sometimes with a polished surface resembling hempseed. They are easily recognised by their insolubility in muriatic acid, and their swelling up and passing into pure lime before the blowpipe. Mulberry calculi contain always an admixture of other substances besides oxalate of lime. These are, uric acid, phosphate of lime, and animal matter in dark flocculi. The colouring matter of these calculi is probably effused blood. Dr. Henry rates the frequency of this species at 1 in 17 of the whole which he has compared; and out of 187 calculi, he found that 17 were formed round *nuclei* of oxalate of lime.

Species 6. The *cystic-oxide calculus.* It resembles a little the triple phosphate, or more exactly magnesian limestone. It is somewhat tough when cut, and has a peculiar greasy lustre. Its usual colour is pale brown, bordering on straw yellow; and its texture is irregularly crystalline. It unites in solution with acids and alkalies, crystallizing with both. Alkohol precipitates it from nitric acid. It does not become red with nitric acid; and it has no effect upon vegetable blues. Neither water, alkohol, nor ether dissolves it. It is decomposed by heat into carbonate of ammonia and oil, leaving a minute residuum of phosphate of lime. This concretion is of very rare occurrence. Dr. Henry states its frequency to the whole as 10 to 985. In two which he examined, the nucleus was the same substance with the rest of the concretion; and in a third, the nucleus of an uric acid calculus was a small spherule of cystic oxide. Hence, as Dr. Marcet has remarked, this oxide appears to be in reality the production of the kidneys, and not, as its name would import, to be generated in the bladder. It might be called with propriety *renal* oxide, if its eminent discoverer should think fit.

Species 7. The *alternating calculus.* The surface of this calculus is usually white like chalk, and friable or semicrystalline, according as the exterior coat is the calcareous or ammonia-magnesian phosphate. They are frequently of a large size, and contain a nucleus of lithic acid. Sometimes the two phosphates form alternate layers round the nucleus. The above are the most common alternating calculi; next are those of oxalate of lime with phosphates; then oxalate of lime with lithic acid; and lastly, those in which the three substances alternate. The alternating, taken all together, occur in 10 out of 25, in Dr. Henry's list; the lithic acid with phosphates, as 10 to 48; the oxalate of lime with phosphates, as 10 to 116; the oxalate of lime with lithic acid, as 10 to 170; the oxalate of lime with lithic acid and phosphates, as 10 to 265.

Species 8. The *compound calculus.* This consists of a mixture of lithic acid with the phosphates in variable proportions, and is consequently variable in its appearance. Sometimes the alternating layers are so thin as to be undistinguishable by the eye, when their nature can be determined only by chemical analysis. This species, in Dr. Henry's list, forms 10 in 235. About 1-40th of the calculi examined by Fourcroy and Vauquelin were compound.

Species 9. has been already described.

In almost all calculi, a central nucleus may be discovered, sufficiently small to have descended through the ureters into the bladder. The disease of stone is to be considered, therefore, essentially and originally as belonging to the kidneys. Its increase in the bladder may be occasioned, either by exposure to urine that contains an excess of the same ingredient as that composing the nucleus, in which case it will be uniformly constituted throughout; or if the morbid nucleus deposit should cease, the concretion will then acquire a coating of the earthy phosphates. It becomes, therefore, highly important to ascertain the nature of the most predominant nucleus. Out of 187 calculi examined by Dr. Henry, 17 were formed round nuclei of oxalate of lime; 3 round nuclei of cystic oxide; 4 round nuclei of the earthy phosphates; 2 round extraneous substances; and in 3 the nucleus was replaced by a small cavity, occasioned probably by the shrinking of some animal matter, round which the ingredients of the calculi (fusible) had been deposited. Rau has shown by experiment, that pus may form the nucleus of an urinary concretion. The remaining 158 calculi of Dr. Henry's list, had central nuclei composed chiefly of lithic acid. It appears also, that in a very great majority of the cases referred to by him, the disposition to secrete an excess of lithic acid has been the essential cause of the origin of stone. Hence it becomes a matter of great importance to enquire, what are the circumstances which contribute to its excessive production, and to ascertain by what plan of diet and medicine this morbid action of the kidneys may best be obviated or removed. A calculus in Mr. White's collection had for its nucleus a fragment of a bougie, that had slipped into the bladder. It belonged to the fusible species, consisting of,

20	phosphate of lime,
60	ammonia-magnesian phosphate,
10	lithic acid,
10	animal matter.
100	

In some instances, though these are comparatively very few, a morbid secretion of the earthy phosphates in excess, is the cause of the formation of stone. Dr. Henry relates the case of a gentleman, who, during paroxysms of gravel, preceded by severe sickness and vomiting, voided urine as opaque as milk, which deposited a great quantity of an impalpable powder, consisting of the calcareous and triple phosphate in nearly equal proportions. The weight of the body was rapidly reduced from 188 to 100 pounds, apparently by the abstraction of the earth of his bones; for there was no emaciation of the muscles corresponding to the above diminution.

The first rational views on the treatment of calculous disorders, were given by Dr. Wollaston. These have been followed up lately by some very judicious observations of Mr. Brande, in the 12th, 15th, and 16th numbers of his Journal; and also by Dr. Marcet, in his excellent treatise already referred to. Of the many substances contained in human urine, there are rarely more than three which constitute gravel; viz. calcareous phosphate, ammonia-magnesian phosphate, and lithic acid. The former two form a white sediment; the latter, a red or brown. The urine is always an acidulous secretion. Since by this excess of acid, the earthy salts, or white matter, are held in solution, whatever disorder of the system, or impropriety of food and medicine, diminishes that acid excess, favours the formation of white deposite. The internal use of acids was shown by Dr. Wollaston to be the appropriate remedy in this case.

White gravel is frequently symptomatic of disordered digestion, arising from excess in eating or drinking; and it is often produced by too farinaceous a diet. It is also occasioned by the indiscréet use of magnèsia, soda water, or alkaline medicines in general. Medical practitioners, as well as their patients, ignorant of chemistry, have often committed fatal mistakes, by considering the white gravel, passed on the administration of alkaline medicines, as the dissolution of the calculus itself; and have hence pushed a practice, which has rapidly increased the size of the stone. Magnesia, in many cases, acts more injuriously than alkali, in precipitating insoluble phosphate from the urine. The acids of urine, which, by their excess, hold the earths in solution, are the phosphoric, lithic, and carbonic. Mr. Brande has uniformly obtained the latter acid, by placing urine under an exhausted receiver; and he has formed carbonate of barytes, by dropping barytes water into urine recently voided.

The appearance of white sand does not seem deserving of much attention, where it is merely occasional, following indigestion brought on by an accidental excess. But if it invariably follows meals, and if it be observed in the urine, not as a mere deposit, but at the time the last drops are voided, it becomes a matter of importance, as the forerunner of other and serious forms of the disorder. It has been sometimes viewed as the *effect* of irritable bladder, where it was in reality the *cause*. Acids are the proper remedy, and unless some peculiar tonic effect be sought for in sulphuric acid, the vegetable acids ought to be preferred. Tartar, or its acid, may be prescribed with advantage, but the best medicine is citric acid, in daily doses of from 5 to 30 grains. Persons returning from warm climates, with dyspeptic and hepatic disorders, often void this white gravel, for which they have recourse to empyrical solvents, for the most part alkaline, and are deeply injured. They ought to adopt an acidulous diet, abstaining from soda water, alkalies, malt liquor, madeira and port; to eat salads, with acid fruits; and if habit requires it, a glass of cyder, champagne, or claret, but the less of these fermented liquors the better. An effervescing draught is often very beneficial, made by dissolving 30 grains of bicarbonate of potassa, and 20 of citric acid, in separate tea-cups of water, mixing the solution in a large tumbler, and drinking the whole during the effervescence. This dose may be repeated 3 or 4 times a-day. The carbonic acid of the above medicine enters the circulation, and passing off by the bladder, is useful in retaining, particularly, the triple phosphate in solution, as was first pointed out by Dr. Wollaston. The bowels should be kept regular by medicine and moderate exercise. The febrile affections of children are frequently attended by an apparently formidable deposit of white sand in the urine. A dose of calomel will generally carry off both the fever and the sand. Air, exercise, bark, bitters, mineral tonics, are in like manner often successful in removing the urinary complaints of grown up persons.

In considering the red gravel, it is necessary to distinguish between those cases in which the sand is actually voided, and those in which it is deposited, after some hours, from originally limpid urine. In the first, the sabulous appearance is an alarming indication of a tendency to form calculi; in the second, it is often merely a fleeting symptom of indigestion. Should it frequently recur, however, it is not to be disregarded.

Bicarbonate of potassa or soda is the proper remedy for the red sand, or lithic acid deposit. The alkali may often be beneficially combined with opium. Ammonia, or its crystallised carbonate, may be resorted to with advantage, where symptoms of indigestion are brought on by the other alkalies; and particularly in red gravel connected with gout, in which the joints and kidneys are affected by turns. Where potassa and soda have been so long employed as to disagree with the stomach, to create nausea, flatulency, a sense of weight, pain, and other symptoms of indigestion, magnesia may be prescribed with the best effects. The tendency which it has to accumulate in dangerous quantities in the intestines, and to form a white sediment in urine, calls on the practitioner to look minutely after its administration. It should be occasionally alternated with other laxative medicines. Magnesia dissolved in carbonic acid, as Mr. Scheweppe used to prepare it many years ago, by the direction of Mr. Brande, is an elegant form of exhibiting this remedy.

Care must be had not to push the alkaline medicines too far, lest they give rise to the deposition of earthy phosphates in the urine.

Cases occur in which the sabulous deposit consists of a mixture of lithic acid with the phosphates. The sediment of urine in inflammatory disorders is sometimes of this nature; and of those persons who habitually indulge in excess of wine; as also of those who, labouring under hepatic affections, secrete much albumen in their urine. Purges, tonics, and nitric acid, which is the solvent of both the above sabulous matters, are the appropriate remedies. The best diet for patients labouring under the lithic deposit, is a vegetable. Dr. Wollaston's fine observation, that the excrement of birds fed solely upon animal matter, is in a great measure lithic acid, and the curious fact since ascertained, that the excrement of the boa constrictor, fed also entirely on animals, is pure lithic acid, concur in giving force to the above dietetic prescription. A week's abstinence from animal food has been known to relieve a fit of lithic acid gravel, where the alkalies were of little avail. But we must not carry the vegetable system so far as to produce flatulency and indigestion.

Such are the principal circumstances connected with the disease of gravel in its incipient or sabulous state. The calculi formed in the kidneys are, as we have said above, either lithic, oxalic, or cystic; and very rarely indeed of the phosphate species. An aqueous regimen, moderate exercise on horseback, when not accompanied with much irritation, cold bathing, and mild aperients, along with the appropriate chemical medicines, must be prescribed in kidney cases. These are particularly requisite immediately after acute pain in the region of the ureter, and inflammatory symptoms have led to the belief that a nucleus has descended into the bladder. Purges, diuretics, and diluents, ought to be liberally enjoined. A large quantity of mucus streaked with blood, or of a purulent aspect, and hæmorrhagy, are frequent symptoms of the passage of the stone into the bladder.

When a stone has once lodged in the bladder, and increased there to such a size as no longer to be capable of passing through the urethra, it is generally allowed by all who have candidly considered the subject, and who are qualified by experience to be judges, that the stone can never again be dissolved; and although it is possible that it may become so loosened in its texture as to be voided piecemeal, or gradually to crumble away, the event is so rare as to be barely probable.

By examining collections of calculi we learn, that in by far the greater number of cases, a nucleus or lithic acid is enveloped in a crust of the phosphates. Our endeavours must therefore be directed towards reducing the excess of lithic acid in the urine to its natural standard; or, on the other hand, to lessen the tendency to the deposition of the phosphates. The urine must be submitted to chemical examination, and a suitable course of diet and medicines prescribed. But the chemical remedies must be regulated nicely, so as to hit the happy equilibrium, in which no deposit will be formed. Here is a powerful call on the physicians and surgeons to make themselves thoroughly versant in chemical science; for they will otherwise commit the most dangerous blunders in calculous complaints.

'The idea of dissolving a calculus of uric acid in the bladder, by the internal use of the caustic alkalies,' says Mr. Brande, 'appears too absurd to merit serious refutation.' In respect to the phosphates, it seems possible by keeping up an unusual acidity in the urine, so far to soften a crust of the calculus, as to make it crumble down, or admit of being abraded by the sound; but this is the utmost that can be looked for; and the lithic nucleus will still remain. 'These considerations,' adds Mr. Brande, 'independent of more urgent reasons, show the futility of attempting the solution of a stone of the bladder by the injection of acid and alkaline solutions. In respect to the alkalies, if sufficiently strong to act upon the uric crust of the calculus, they would certainly injure the coats of the bladder; they would otherwise become inactive by combination with the acids of the urine, and they would form a dangerous precipitate from the same cause.'—'It therefore appears to me that Fourcroy and others, who have advised the plan of injection, have thought little of all these obstacles to success, and have regarded the bladder as a lifeless receptacle into which, as into an India rubber bottle, almost any solvent might be injected with impunity.'—*Journal of Science*, vol. viii. p. 216.

It does not appear that the peculiarities of water in different districts, have any influence upon the production of calculous disorders. Dr. Wollaston's discovery of the analogy between urinary and gouty concretions has led to the trial in gravel of the *vinum colchici*, the specific for gout. By a note to Mr. Brande's dissertation we learn, that benefit has been derived from it in a case of red gravel.

Dr. Henry confirms the above precepts in the following decided language. 'These cases, and others of the same kind, which I think it unnecessary to mention, tend to discourage all attempts to dissolve a stone supposed to consist of uric acid, after it has attained considerable size in the bladder; all that can be effected under such circumstances by alkaline medicines appears, as Mr. Brande has remarked, to be the precipitating upon it a coating of the earthy phosphates from the urine, a sort of concretion which, as has been observed by various practical writers, increases much more rapidly than that consisting of uric acid only. The same unfavourable inference may be drawn also from the dissections of those persons in whom a stone was supposed to be dissolved by alkaline medicines; for in these instances it has been found either encysted, or placed out of the reach of the sound by an enlargement of the prostate gland.'

The urinary calculus of a dog examined by Dr. Pearson, was found to consist principally of the phosphates of lime and ammonia, with animal matter. Several taken from horses were of a similar composition. One of a rabbit consisted chiefly of carbonate of lime and animal matter, with perhaps a little phosphoric acid. A quantity of sabulous matter, neither crystallised nor concrete, is sometimes found in the bladder of the horse: in one instance there were nearly 45 pounds. These appear to consist of carbonate of lime and animal matter. A calculus of a cat gave Fourcroy three parts of carbonate, and one of the phosphate of lime. That of a pig, according to Berthollet, was phosphate of lime.

The renal calculus in man appears to be of the same nature as the urinary. In that of the horse, Fourcroy found 3 parts of carbonate, and one of phosphate of lime. Dr. Pearson, in one instance, carbonate of lime and animal matter; in two others, phosphates of lime and ammonia, with animal matter.

Arthritic calculi, or those formed in the joints of gouty persons, were once supposed to be carbonate of lime, whence they were called chalkstones; afterward it was supposed that they were phosphate of lime; but Dr. Wollaston has shown, that they are lithate of soda. The calculi found sometimes in the pineal, prostate, salivary, and bronchial glands, in the pancreas, in the corpora cavernosa penis, and between the muscles, as well as the tartar, as it is called, that incrusts the teeth, appear to be phosphate of lime. Dr. Crompton, however, examined a calculus taken from the lungs of a deceased soldier, which consisted of lime 45, carbonic acid 37, albumen and water 18. It was very hard, irregularly spheroidal, and measured about 6½ inches in circumference.

It has been observed, that the lithic acid, which constitutes the chief part of most human urinary calculi, and abounds in the arthritic, has been found in no phytivorous animal; and hence has been deduced a practical inference, that abstinence from animal food would prevent their formation. But we are inclined to think this conclusion too hasty. The cat is carnivorous; but it appeared above, that the calculus of that animal is equally destitute of lithic acid. If, therefore, we would form any deduction with respect to regimen, we must look for something used by man, exclusively of all other animals; and this is obviously found in fermented liquors, but apparently in nothing else: and this practical inference is sanctioned by the most respectable medical authorities.

The following valuable *criteria* of the different kinds of urinary calculi, have been given by M. Berzelius in his treatise on the use of the blowpipe:

'1. We may recognise *calculi* formed of *uric acid*, from their being carbonized and smoking with an animal odour when heated by themselves on charcoal or platinum-foil. They dwindle away at the blowpipe flame. Towards the end, they burn with an increase of light; and leave a small quantity of very white alkaline ashes.

'To distinguish these concretions from other substances, which comport themselves in the above manner, we must try a portion of the calculus by the humid way. Thus a tenth of a grain of this calculus being put on a thin plate of glass or platinum, along with a drop of nitric acid, we must heat it at the flame of the lamp. The uric acid dissolves with effervescence. The matter, when dried with precaution to prevent it from charring, is obtained in a fine red colour. If the calculus contains but little uric acid, the substance sometimes blackens by this process. We must then take a new portion of the concretion, and after having dissolved it in nitric acid, remove it from the heat: the solution, when nearly dry, is to be allowed to cool and become dry. We then expose it, sticking to its support, to the warm vapour of caustic ammonia. (From water of ammonia heated in a tea-spoon.) This ammoniacal vapour developes a beautiful red colour in it. We may also moisten the dried matter with a little weak water of ammonia.

'If the concretions are a mixture of uric acid, and earthy phosphate, they carbonize and consume like the above, but their residuum is more bulky; it is not alkaline, nor soluble in water. They exhibit with nitric acid and ammonia, the fine red colour of uric acid. Their ashes contain phosphate of lime, or of lime and magnesia.

'2. *The calculi of urate of soda* are hardly met with except in the concretions round the articulations of gouty patients. When heated alone upon charcoal, they blacken, exhaling an empyreumatic animal odour; they are with difficulty reduced into ashes, which are strongly alkaline, and are capable of vitrifying silica. When there are earthy salts (phosphates) in these concretions, they afford a whitish or opaque grey glass.

'3. *The calculi of urate of ammonia* comport themselves at the blowpipe like those of uric acid. A drop of caustic potassa makes them exhale, at a moderate heat, much ammonia. We must not confound this odour with the slight ammoniaco-lixivial smell, which potassa disengages from the greater part of animal substances. Urate of soda is likewise found in these calculi.

'4. *Calculi of phosphate of lime.* They blacken, with the exhalation of an empyreumatic animal odour, without melting of themselves at the blowpipe, but whiten into on evident calcareous phosphate. With soda they swell up without vitrifying. Dissolved in boracic acid, and fused along with a little iron, they yield a bead of phosphuret of iron.

'5. *Calculi of ammoniaco-magnesian phosphate*, heated alone on a plate of platinum, exhale the empyreumatic animal odour, at the same time blackening, swelling up, and becoming finally greyish-white. A kind of greyish-white enamel is in this manner obtained. With borax they melt into a glass, which is transparent, or which becomes of a milky-white on cooling. Soda in small quantity causes them to fuse into a frothy white slag, a larger quantity of soda makes them infusible. They yield, with iron and boracic acid, a bead of phosphuret of iron; with nitrate of cobalt, a glass of a deep red or brown. If salts of lime exist in these concretions, the mixture of them is less fusible.

'6. *Calculi of oxalate of lime*, exposed to the blowpipe, exhale at first the urinous smell; they become first of a dull colour at the flame, and afterwards their colour brightens. What remains after a moderate ignition, effervesces with nitric acid. After a smart jet of the flame, there remains quick-lime on the charcoal, which reacts like an alkali on the colour of litmus, wild mallow flower, or cabbage, and slakes with water. But this does not happen when the residuum consists of calcareous phosphate.

'7. *The siliceous calculus*, heated alone, leaves sub-coriaceous or infusible ashes. Treated with a little soda, these dissolve with effervescence, but slowly, leaving a bead of glass of a grey colour, or of little transparency.

'8. Lastly, *the cystic oxide calculi* afford nearly the same results as uric acid at the blowpipe. They readily take fire, burning with a bluish-green flame, without melting, with the disengagement of a lively and very peculiar acid odour, which has some affinity to that of cyanogen. Their ashes, which are not alkaline, redissolved by a jet of the flame, into a greyish-white mass. They do not yield a red colour in their treatment with nitric acid, like the uric acid concretions.'"

The causes of the Generation of Urinary Calculi.

To enquire into the causes by which urinary concretions are produced, is both interesting and useful, however attended with the greatest difficulties. The writings of medical authors are full of conjectures and hypotheses with regard to this subject, on which nothing could be ascertained before we had acquired an accurate knowledge of the nature of urinary concretions. It is owing to this circumstance that the most enlightened physicians acquiesced in ascribing the immediate cause of them to a superabundance of terreous matter in the urine; and Boerhaave, as well as, particularly, Van Swieten, imagined that the urine of all men contained calculous matter in the natural state, and that, for the generation of stones, a nucleus was only required, to attract it. That this may be the case, in some instances, is proved by frequent experience; but stones produced by foreign bodies, that have accidentally got into the urethra or bladder, are always white and composed of phosphates of earths, and seldom or never covered with lithic acid, a substance which is observed to form the stones that most frequently occur; but even in these the nucleus consists of a substance formed in the body itself, as a particle descended from the kidneys, &c. which must, therefore, have necessarily originated in a peculiar internal cause. A superabundance of uric acid in stony patients, and its more copious generation than in a sound state, though it seems to be one of the principal and most certain causes, is by no means satisfactory, as it only explains the precipitation of stony matter from the urine, but not why it unites in strata. A coagulating substance is required for separating, attracting, and, as it were, agglutinating the condensible particles that are precipitated. This substance is undoubtedly the animal matter which we have constantly found in all calculous masses, and which seems to constitute the basis of stones, like the membraneous gelatina that of bones. It is known that the urine of calculous patients is generally muddy, ductile, in threads, slimy, and as if mixed with albumen, which quality it obtains at the moment when the ammonia is disengaged, or on the addition of potassa that separates it from the acid in which it was dissolved; and in all cases of superabundance of lithic acid the urine contains a great quantity of that animal matter, which promotes the precipitation of it, and attracts and unites the particles thus separated. Hence it appears, that every thing capable of increasing the quantity of that pituitous gluten in the urine, may be considered as the remote cause of the formation of calculi. And the old ideas on pituitous temperaments, or superabundant pituita, &c. which were thought to dispose people to a calculus, seem to be connected with the late discoveries on the nature of urinary stones. Though the animal matter appears to be different in different calculi, yet it is certain, that every calculous substance contains an animal gluten, from which its concrete and solid state arises; whence we may fairly state the superabundance of that substance as the chief and principal cause of the formation of calculi.

There are, however, other causes which seem to have a particular influence on the nature of urinary stones, and the strata in which they are formed; but it is extremely difficult to penetrate and to explain them. We are, for instance, entirely ignorant of the manner in which urinary stones are formed from the oxalate of lime; though, from their occurring more frequently in children than in adults, we might be entitled to ascribe them to a disposition to acor, a cause considered by Boerhaave as the general source of a great number of diseases incident to the infantile age. This opinion seems to be proved by the ideas of Bonhomme, physician at Avignon, on the oxalic or saccharic acid, as the cause of mollities ossium in the rickets; by this acid being discovered in a species of saliva by Brugnatelli; and, lastly, by an observation of Turgais, who found this acid in the urine of a child diseased with worms. We but rarely observe saccharic acid in the human body, which appears to be mostly adventitious, and by which the animal matter is rendered coagulable, and deposited, or precipitated, with the oxalate of lime; or the oxalic acid decomposes the phosphate of lime, and forms an insoluble combination, incapable of being any longer kept dissolved in the urine. It is, however, extremely difficult to determine how far the constitution of the body is connected with that particular disposition in the urine, of precipitating sometimes phosphate of lime mixed with oxalate of lime, sometimes phosphate of ammoniacal magnesia, either by itself or mixed with lithic acid, &c. &c. Who can explain the reason why, of 600 stones, there were only two in which siliceous earth could be traced? Still more difficult is it to explain the causes why the above substances precipitate either at once or in different strata; but it may suffice to have shown how many observations and experiments are required, and what accurate attention and perseverance are necessary, in order to throw light on so difficult a subject.

The means to be employed in calculous complaints must vary according to circumstances. Permanent relief can be obtained only by the removal of the morbid concretion; and where this is of too large a size to be passed by the natural outlet, the operation of lithotomy becomes necessary. Various remedies indeed have been proposed as capable of dissolving urinary calculi; and some of them are certainly useful in palliating the symptoms, and perhaps preventing the formation of fresh calculous matter: but experience has not sanctioned their efficacy as actual lithontriptics; and by delaying the operation, we not only incur the risk of organic disease being produced, but the concretion may also become friable externally, so as to be with more difficulty removed. Sometimes, however, the advanced age of the patient, the complication with organic disease, or the exhausted state of the system, may render an operation inexpedient; or he may not be willing to submit to it; we shall then find some advantage from the use of chemical remedies, according to the morbid quality of the urine; that is generally from alkaline or earthy preparations, where a red deposit appears, and from acids where there is a white sediment. Tonic medicines may also be useful, and some of the mild astringents, especially uva ursi, and occasional narcotics, where violent pain attends: sometimes an inflammatory tendency may require fomentations, the local abstraction of blood, and other antiphlogistic measures. The most likely plan of effecting a solution of the calculus must certainly be that proposed by Fourcroy, namely, injecting suitable liquids into the bladder. The most common calculi, containing uric acid, are readily soluble in a solution of potassa, or soda, weak enough to be held in the mouth, or even swallowed without inconvenience; those which consist of phosphoric acid neutralised by lime, or other base, the next in frequency, dissolve in nitric or muriatic acid of no greater strength; the most rare variety, made up mostly of oxalate of lime, may be dissolved, but very slowly, in nitric acid, or solutions of the fixed alkaline carbonates, weak enough not to irritate the bladder. However, it is not easy to ascertain which of these solvents is proper in a particular case, for most calculi are not uniform throughout, owing probably to the urine having varied during their formation, so that the examination of this secretion will not certainly indicate the injection required. The plan recommended therefore, is, the bladder having been evacuated, and washed out with tepid water, to inject first the alkaline solution heated to the temperature of the body, and direct it to be retained for half an hour, or longer, if the person can bear it; then to the liquor voided and filtered add a little muriatic acid, which will cause a white precipitate, if there be any uric acid dissolved; and so long as this happens, the same injection should be used, otherwise diluted muriatic acid is to be thrown in, and ammonia added to it when discharged; whereby phosphate of lime, if there be any, is precipitated: and when neither of these succeeds, diluted nitric acid is to be tried; in each case varying the injection from time to time, as that previously used loses its efficacy. However, there appears one source of error in this method; namely, that the urine secreted, while the liquid is retained, may give rise to a precipitate, though none of the calculous may have been dissolved; it would therefore be proper to examine the urine previously, as well as occasionally during the use of injections, and, if necessary, correct its quality by the exhibition of proper internal medicines. See *Lithontriptics* and *Lithotomy*.

Calculus biliaris. See *Gall-stone*.

CALDA′RIUM. (From *caleo*, to make hot.) A vessel in the baths of the ancients, to hold hot water.

CALEFA′CIENT. (*Calefaciens*; from *calidus*, warm, and *facio*, to make.) A medicine, or other substance, which excites a degree of warmth in the parts to which it is applied; as *piper*, *spiritus vini*, &c. They belong to the class of stimulants.

CALE′NDULA. (*Quod singulis calendis, i. e. mensibus, florescat;* so called because it flowers every month.) 1. The name of a genus of plants in the Linnæan system. Class, *Syngenesia*; Order, *Polygamia necessaria*.

2. The pharmacopœial name of the single marigold. See *Calendula officinalis*.

Calendula alpina. The mountain arnica. See *Arnica montana*.

Calendula arvensis. The wild marigold. See *Caltha palustris*.

Calendula officinalis. Garden marigold. *Calendula sativa*; *Chrysanthemum*; *Sponsa solis*; *Caltha vulgaris*. The flowers and leaves of this plant, *Calendula:—seminibus cymbiformibus, muricatis, incurvatis omnibus*, of Linnæus, have been exhibited medicinally: the former, as aperients in uterine obstructions and icteric disorders, and as diaphoretics in exanthematous fevers; the latter, as gentle aperients, and to promote the secretions in general.

Calendula palustris. Common single marsh-marigold. See *Caltha palustris*.

CA′LENTURE. A febrile delirium, said to be peculiar to sailors, wherein they imagine the sea to be green fields, and will throw themselves into it if not restrained. Bonetus, Dr. Oliver, and Dr. Stubbs, give an account of it.

Cale′sium. The Indian name of a tree which grows in Malabar, the bark of which made into an ointment with butter, cures convulsions from wounds, and heals ulcers. The juice of the bark cures the aphthæ, and, taken inwardly, the dysentery.—*Ray*.

Calf's snout. See *Antirrhinum*.

Ca′li. (Arabian.) The same as kali.

Calicha′pa. The white-thorn.

CA′LIDUS. In medical language, it is commonly used for animal heat, or the visvitæ: thus, *calidum animale innatum*.

Calidæ plantæ. (From *calor*, heat.) Plants that are natives of warm climates.

Calie′ta. (From καλιης, a nest, which it somewhat resembles.) *Calliette*. A fungus growing on the juniper-tree.

CALI′GO. (*Caligo, ginis.* fœm.) A disease of the eye, known by diminished or destroyed sight; and by the interposition of a dark body between the object and the retina. It is arranged by Cullen in the class *Locales*, and order *Dysæsthesiæ*. The species of caligo are distinguished according to the situation of the interposed body: thus *caligo lentis, caligo corneæ, caligo pupillæ, caligo humorum*, and *caligo palpebrarum*.

Caliha′cha. The cassia-lignea, or cassia-tree of Malabar.

Cali′mia. The lapis calaminaris.

CA′LIX. (*Calix, icis.* m.; from καλυπτω, to cover.) See *Calyx*.

Callæ′um. (From καλλυνω, to adorn.) *Callæon*. The gills of a cock, which Galen says, is food not to be praised or condemned.

Calle′na. A kind of salt-petre.

Ca′lli. Nodes in the gout.—*Galen*.

Ca′llia. (From καλος, beautiful.) A name of the chamomile.

Callible′phara. (From καλος, good, and βλεφαρον, the eyelid.) Medicines, or compositions, appropriated to the eyelids.

CALLICO′CCA. The name of a genus of plants in the Linnæan system. Class, *Pentandria*; Order, *Monogynia*.

Callicocca ipecacuanha. The plant from which ipecacuan root is obtained was long unknown; it was said by some writers to be the *Psychotria emetica*: Class, *Pentandria*; Order, *Monogynia*: by others, the *Viola ipecacuanha*, a syngenesious plant of the order *Monogynia*. It is now ascertained to be neither, but a small plant called *Callicocca ipecacuanha*. There are three sorts of ipecacuan to be met with in our shops, viz. the ash-coloured or grey, the brown, and the white.

The ash-coloured is brought from Peru, and is a small wrinkled root, bent and contorted into a great variety of figures, brought over in short pieces, full of wrinkles, and deep circular fissures, down to a small white woody fibre that runs in the middle of each piece: the cortical part is compact, brittle, looks smooth and resinous upon breaking: it has very little smell; the taste is bitterish and subacrid, covering the tongue as it were, with a kind of mucilage.

The brown is small, somewhat more wrinkled than the foregoing; of a brown or blackish colour without, and white within: this is brought from Brazil.

The white sort is woody, and has no wrinkles, nor any perceptible bitterness in taste. The first, the ash-coloured or grey ipecacuan, is that usually preferred for medicinal use. The brown has been sometimes observed, even in a small dose, to produce violent effects. The white, though taken in a large one, has scarcely any effect at all. Experience has proved that this medicine is the safest emetic with which we are acquainted, having this peculiar advantage, that, if it does not operate by vomit, it readily passes off by the other emunctories. Ipecacuan was first introduced as an infallible remedy against dysenteries, and other inveterate fluxes, as diarrhœa, menorrhagia, leucorrhœa, &c. and also in disorders proceeding from obstructions of long standing; nor has it lost much of its reputation by time: its utility in these cases is thought to depend upon its restoring perspiration. It has also been successfully employed in spasmodic asthma, catarrhal and consumptive cases. Nevertheless, its chief use is as a vomit, and in small doses joined with opium, as a diaphoretic. The officinal preparations are the *pulvis ipecacuanhæ compositus*, and the *vinum ipecacuanhæ*.

Calli'creas. (From *καλος*, good, and *κρεας*, meat; so named from its delicacy as food.) Sweet-bread. See *Pancreas*.

Calli'gonum. (From *καλος*, beautiful, and *γονυ*, a knot, or joint; so named from its being handsomely jointed, like a cane.) The polygonum, or knot-grass.

Callioma'rchus. The Gaullic name, in Marcellus Empiricus, of colt's foot.

Ca'llion. A kind of night-shade.

Calliphy'llum. (From *καλλος*, beauty, and *φυλλον*, a leaf.) See *Adianthum*.

Callistru'thia. (From *καλος*, good, and *ςρυθος*, a sparrow; because it was said to fatten sparrows.) A fig mentioned by Pliny, of a good taste.

CALLITRI'CHE. (From *καλλος*, beauty, and *ϑριξ*, hair; so named because it has the appearance of long, beautiful hair; or, according to Littleton, because it nourishes the hair, and makes it beautiful.) 1. The name of a genus of plants in the Linnæan system. Class, *Monandria*; Order, *Digynia*. Water starwort; Water chickweed.

2. The herb maidenhair. See *Adianthum*.

CALLO'NE. (From *καλος*, fair.) Hippocrates uses this word to signify that decency and gravity of character and deportment which it is necessary that all medical men should be possessed of.

CALLO'SITAS. Callosity, or preternatural hardness.

CALLOSITY. *Calositas.* Hardness.

CALLOSUS. Hard. Applied in surgery to parts which are morbidly hard; and, in botany, to seeds which are hard; as those of the *Citrus medica*.

CA'LLOUS. *Callosus.* Hardened or indurated; as the callous edges of ulcers.

CA'LLUS. (*Callus*, *i.* m.; and *Callum*, *i.* n.) 1. The bony matter deposited between the divided ends of broken bones, about the fourteenth day after the fracture. It is in reality nothing more than the new ossific substance formed by a process of nature, very similar to the growth of any other part of the body.

2. A preternatural hardness, or induration, of any fleshy part.

3. This term is applied in Good's Nosology to that species of ecphyma, which is characterised by callous extuberant thickening of the cuticle; insensible to the touch.

Caloca'tanus. (From *καλος*, beautiful, and *κατανον*, a cup; so called from the beauty of its flower and shape.) The wild poppy. See *Papaver rhœas*.

CALO'MELAS. (From *καλος*, good, and *μελας*, black; from its virtues and colour.) The preparation called Æthiops mineral, or *hydrargyrus cum sulphure*, was formerly so named.

2. The chloride of mercury. See *Hydrargyri submurias*.

CALO'RIC. (*Caloricum*; from *calor*, heat.) Heat; Igneous fluid.

Heat and cold are perceptions of which we acquire the ideas from the senses; they indicate only a certain state in which we find ourselves, independent of any exterior object. But as these sensations are for the most part produced by bodies around us, we consider them as causes, and judging by appearances, we apply the terms *hot*, or *cold*, to the substances themselves; calling those bodies *hot*, which produce in us the sensation of heat, and those *cold*, which communicate the contrary sensation.

This ambiguity, though of little consequence in the common affairs of human life, has led unavoidably to confusion and perplexity in philosophical discussions. It was to prevent this, that the framers of the new nomenclature adopted the word *caloric*, which denotes that which produces the sensation of heat.

Theories of Heat.

Two opinions have long divided the philosophical world concerning the nature of heat.

1. The one is; that the cause which produces the sensation of heat, is a real or distinct substance, universally pervading nature, penetrating the particles or pores of all bodies, with more or less facility, and in different quantities.

This substance, if applied to our system in a greater proportion than it already contains, warms it, as we call it, or produces the sensation of heat; and hence it has been called *caloric* or *calorific*.

2. The other theory concerning heat is; that the cause which produces that sensation is *not* a separate or self-existing substance; but that it is merely like gravity, a property of matter; and that it consists in a specific or *peculiar motion*, or *vibration* of the particles of bodies.

The arguments in favour of the first theory have been principally deduced from the evolution and absorption of heat during chemical combinations; those of the latter are chiefly founded on the production of heat by friction. For it has been observed, that whatever is capable of producing motion in the particles of any mass of matter, excites heat. Count Rumford and Professor Davy have paid uncommon attention to this fact, and proved, that heat continues to be evolved from a body subjected to friction, so long as it is applied, and the texture or form of the body not altered.

All the effects of heat, according to this theory, depend therefore entirely on the vibratory motion of the particles of bodies. According as this is more or less intense, a higher or lower temperature is produced; and as it predominates over, is nearly equal or inferior to the attraction of cohesion, bodies exist in the gaseous, fluid, or solid state.

Different bodies are susceptible of it in different degrees, and receive and communicate it with different celerity. From the generation, communication, and attraction of this repulsive motion, under these laws, all the phenomena ascribed to heat are explicable.

Each of these theories has been supported by the most able philosophers, and given occasion to the most important disputes in which chemists have been engaged; which has contributed in a very particular manner to the advancement of the science. The obscurity of the subject, however, is such, that both parties have been able to advance most plausible arguments.

Setting aside all enquiries concerning the merits of these different doctrines, we shall confine ourselves to the general effects which heat produces on different bodies. For the phenomena which heat presents, and their relation to each other, may be investigated with sufficient precision, though the materiality or immateriality of it, may remain unknown to us.

Nature of Heat.

Those who consider heat as matter, assert that caloric exists in two states, namely, in combination, or at liberty.

In the first state it is not sensible to our organs, nor indicated by the thermometer; it forms a constituent part of the body; but it may be brought back to the state of sensible heat. In this state it affects animals with the sensation of heat. It therefore has been called sensible or free heat, or fire; and is synonymous with uncombined caloric, thermometrical caloric, caloric of temperature, interposed caloric, &c. expressions now pretty generally superseded.

From the diversity of opinions among chemists respecting the nature of caloric, several other expressions have been introduced, which it is proper to notice. For instance, by *specific heat* is understood, the relative quantities of caloric contained in equal weights of different bodies at the same temperature. *Latent heat* is the expression used to denote that quantity of caloric which a body absorbs when changing its form. It is, however, more properly called *caloric of fluidity*. The disposition, or property, by which different bodies contain certain quantities of caloric, at any temperature, is termed their *capacity for heat*. By the expression of *absolute heat*, is understood the whole quantity of caloric which any body contains.

Methods of exciting and collecting heat.

Of the different methods of exciting heat, the following are the most usual:

1. *Percussion or Collision.* This method of producing heat is the simplest, and therefore it is generally made use of in the common purposes of life for obtaining fire.

When a piece of hardened steel is struck with a flint, some particles of the metal are scraped away from the mass, and so violent is the heat which follows the stroke, that it melts and vitrifies them. If the fragments of steel are caught upon paper, and viewed with a microscope, most of them will be found perfect spherules, and very highly polished. Their sphericity demonstrates that they have been in a fluid state, and the polish upon their surface, shows them to be vitrified.

No heat, however, has been observed to follow the percussion of liquids, nor of the softer kind of bodies which yield to a slight impulse.

2. *Friction.* Heat may likewise be excited by mere friction. This practice is still retained in some parts of the world. The natives of New Holland are said to produce fire in this manner, with great facility, and spread it in a wonderful manner. For that purpose, they take two pieces of dry wood; one is a stick, about eight or nine inches long, and the other piece is flat; the stick they bring to an obtuse point at one end, and pressing it upon the other piece, they turn it very nimbly, by holding it between both hands, as we do a chocolate-mill, often shifting their hands up, and then moving down upon it, in order to increase the pressure as much as possible. By this method they get fire in a few minutes, and from the smallest spark they increase it with great speed and dexterity.

If the irons at the axis of a coach-wheel are applied to each other, without the interposition of some unctuous matter to keep them from immediate contact, they will become so hot when the carriage runs swiftly along, as to set the wood on fire; and the fore-wheels, being smallest, and making most revolutions in a given time, will be most in danger.

The same will happen to mill-work, or to any other machinery.

It is no uncommon practice in this country, for blacksmiths to use a plate of iron as an extemporaneous substitute for a tinder-box; for it may be hammered on an anvil till it becomes red hot, and will fire a brimstone match. A strong man who strikes quick, and keeps turning the iron so that both sides may be equally exposed to the force of the hammer, will perform this in less time than would be expected.

If, in the coldest season, one dense iron plate be laid on another, and pressed together by a weight, and then rubbed upon each other by reciprocal motions, they will gradually grow so hot as, in a short time, to emit sparks, and at last become ignited.

It is not necessary that the substances should be very hard; a cord rubbed backwards and forwards swiftly against a post or a tree will take fire.

Count Rumford and Professor Pictet have made some very ingenious and valuable experiments concerning the heat evolved by friction.

3. *Chemical Action.* To this belongs the heat produced by combustion. There are, besides this, many chemical processes wherein rapid chemical action takes place, accompanied with a development of heat, or fire, and flame.

4. *Solar Heat.* It is well known that the solar rays, when collected by a mirror, or lens, into a focus, produce the most astonishing effects.

Dr. Herschel has discovered that there are rays emitted from the sun, which have not the power of illuminating or producing vision: and that these are the rays which produce the heat of the solar light.

Consequently, heat is emitted from the sun in rays, but these rays are not the same with the rays of light.

5. *The Electric Spark, and Galvanism.* The effects of electricity are too well known in this point of view, to need any description.

Galvanism has of late become a powerful instrument for the purpose of exciting heat. Not only easily inflammable substances, such as phosphorus, sulphur, &c. have been fired, but likewise, gold, silver, copper, tin, and the rest of the metals, have been burnt by means of galvanism.

General Effects of Heat.

The first and most obvious effect which heat produces on bodies, is its expansive property. Experience has taught us that, at all times, when bodies become hot, they increase in bulk. The bodies experience a dilatation which is greater in proportion to the accumulation of caloric, or, in other words, to the intensity of the heat. This is a general law, which holds good as long as the bodies have suffered no change either in their combination or in the quantity of their chemical principles.

This power, which heat possesses, consists, therefore, in a constant tendency to separate the particles of bodies. Hence philosophers consider heat as the *repulsive power* which acts upon all bodies whatever, and which is in constant opposition to the power of attraction.

The phenomena which result from these mutual actions, seem, as it were, the secret springs of nature. Heat, however, does not expand all bodies equally, and we are still ignorant of the laws which it follows.

1. *Expansion of Fluid Bodies.* Take a glass globe, with a long slender neck (called a bold heat;) fill it up to the neck with water, ardent spirit, or any other fluid which may be coloured with red or black ink, in order to be more visible, and then immerse the globe of the instrument in a vessel of hot water; the included fluid will instantly begin to mount into the neck. If it be taken out of the water and brought near the fire,

it will ascend more and more, in proportion as it becomes heated; but, upon removing it from the source of heat, it will sink again: a clear proof that caloric dilates it, so as to make it occupy more space when hot than when cold. These experiments may, therefore, serve as a demonstration that heat expands *fluid* bodies.

2. *Expansion of Aëriform Bodies.* Take a bladder partly filled with air, the neck of which is closely tied, so as to prevent the inclosed air from escaping, and let it be held near a fire. The air will soon begin to occupy more space, and the bladder will become gradually distended; on continuing the expansion of the air, by increasing the heat, the bladder will burst with a loud report.

3. *Expansion of Solid Bodies.* If we take a bar of iron, six inches long, and put it into a fire till it becomes red-hot; and then measure it in this state accurately, it will be found 1-20th of an inch longer than it was before; that is about 120th part of the whole. That the metal is proportionally expanded in breadth, will be seen by trying to pass it through an aperture which is fitted exactly when cold, but which will not admit it when red-hot. The bar is, therefore, increased in length and diameter.

To discover the minutest changes of expansion by heat, and the relative proportions thereof, instruments have been contrived, called *Pyrometers*, the sensibility of which is so delicate as to show an expansion of 1-100,000th of an inch.

It is owing to this expansion of metals, that the motion of time-pieces is rendered erroneous; but the ingenuity of artists has discovered methods of obviating this inaccuracy, by employing the greater expansion of one metal, to counteract the expansion of another; this is effected in what is called the grid-iron pendulum. Upon the same principle, a particular construction of watches has been contrived.

The expansion of metals is likewise one of the principal reasons that clocks and watches vary in winter and summer, when worn in the pocket, or exposed to the open air, or when carried into a hotter or a colder climate. For the number of the vibrations of the pendulum is always in the sub-duplicate ratio of its length, and as the length is changed by heat and cold, the times of vibration will be also changed. The quantity of alteration, when considered in a single vibration, is exceedingly small, but when they are often repeated, it will be very sensible. An alteration of one-thousandth part in the time of a single vibration of a pendulum which beats seconds, will make a change of eighty-six whole vibrations in twenty-four hours.

As different metals expand differently with the same degree of heat; those musical instruments, whose parts are to maintain a constant true proportion, should never be strung with different metals. It is on this account that harpsichords, &c. are out of tune by a change of temperature.

Bodies which are brittle, or which want flexibility, crack or break if suddenly heated. This likewise depends upon the expansive force of heat, stretching the surface to which it is applied, while the other parts, not being equally heated, do not expand in the same ratio, and are therefore torn asunder or break. Hence thin vessels stand heat better than thick ones. The same holds, when they are suddenly cooled.

Measurement of Heat.

Upon the expansive property of heat, which we have considered before, is founded its artificial measurement. Various means have been employed to assist the imperfection of our sensations in judging of the different degrees of heat, for our feelings unaided afford but very inaccurate information concerning this matter; they indicate the presence of *heat*, only when the bodies presented to them are *hotter* than the actual temperature of our organs of feeling. When those bodies are precisely of the same temperature with our body, which we make the standard of comparison, we then are not sensible of the presence of heat in them. When their temperature is less than that of our bodies, their contact gives us what is called the sensation of cold.

The effects of heat upon material bodies in general, which are easily visible to us, afford more precise and determinate indications of the intensity, than can be derived from our feelings alone. The ingenuity of the philosopher and artist has therefore furnished us with instruments of measuring the relative heat or temperature of bodies. These instruments are called *Thermometers* and *Pyrometers*. By these, all degrees are measurable, from the slightest to that of the most intense heat. See *Thermometer* and *Pyrometer*.

Exceptions to the Expansion by Heat.

Philosophers have noticed a few exceptions to the law of heat expanding bodies. For instance; water, when cooled down within about 7° of the freezing point, instead of contracting on the farther deprivation of heat, actually expands.

Another seeming exception is manifested in alumine or clay; others occur in the case of cast-iron, and a few other metals. Alumine contracts on being heated, and cast-iron, bismuth, &c. when fully fused, are more dense than when solid; for, as soon as they become so, they decrease in density, they expand in the act of cooling, and hence the sharpness of figures upon iron which has been cast in moulds, compared to that of many other metals.

Some philosophers have persuaded themselves that these exceptions are only *apparent*, but not really true. They say when water freezes, it assumes a crystalline form, the crystals cross each other and cause numerous vacuities, and thus the ice occupies more space. The same is the case with fused iron, bismuth, and antimony. The contraction of clay is considered owing to the loss of water, of which it loses a part at every increased degree of temperature hitherto tried; there is, therefore, a loss of matter; and a reduction of volume must follow: but others assert, that this only happens to a certain extent.

Mr. Tilloch has published a brief examination of the received doctrines respecting heat and caloric, in which these truths are more fully considered, together with many other interesting facts relative to the received notions of heat.

Equal Distribution of Heat.

If a number of bodies of different temperatures are placed in contact with each other, they will all at a certain time acquire a temperature, which is intermediate; the caloric of the hottest body will diffuse itself among those which are heated in a less degree, till they have all acquired a certain mean temperature. Thus, if a bar of iron, which has been made red-hot, be kept in the open air, it does not retain the heat which it had received, but becomes gradually colder and colder, till it arrives at the temperature of the bodies in its neighbourhood. On the other hand, if we cool down the iron bar by keeping it for some time covered with snow, and then carry it into a warm room, it does not retain its low temperature, but becomes gradually hotter, till it acquires the temperature of the room. It is therefore obvious, that in the one instance the temperature is lowered, and in the other it is raised.

These changes of temperature occupy a longer or a shorter time according to the nature of the body, but they always take place at last. This law itself is, indeed, familiar to every one: when we wish to heat a body, we carry it towards the fire: when we wish to cool it, we surround it by cold bodies.

Propagation of Heat.

We have seen, that when bodies of higher temperature than others are brought into contact with each other, the heat is propagated from the first to the second, or the colder body deprives the warmer of its excess of heat. We shall now see that some bodies do so much more quickly than others. Through some bodies caloric passes with undiminished velocity, through others its passage is prodigiously retarded.

This disposition of bodies of admitting, under equal circumstances, the refrigeration of a heated body within a shorter or a longer time, is called *the power of conducting heat*; and a body is said to be a *better* or *worse conductor of heat*, as it allows the refrigeration to go on quicker or slower. Those bodies, therefore, which possess the property of letting heat pass with facility, are called *good conductors*, those through which it passes with difficulty are called *bad conductors*, and those through which it is supposed not to pass at all, are called *non-conductors*; thus we say, in common language, some bodies are *warm*, or capable of preserving warmth, and from this arises the great difference in the sensation excited by different bodies, when applied at the same temperature to our organs of feeling. Hence, if we immerse our hand in mercury, we feel a greater sensation of cold than when we immerse it in water, and a piece of metal appears to be much colder than a piece of wood, though their temperatures, when examined by means of the thermometer, are precisely the same.

It is probable that all solids conduct heat in some degree, though they differ very much in their conducting power. Metals are the best conductors of heat; but the conducting powers of these substances are by no means equal. Stones seem to be the next best conductors. Glass conducts heat very slowly; wood and charcoal still slower; and feathers, silk, wool, and hair, are still worse conductors than any of the substances yet mentioned.

The best conductors of electricity and galvanism are also the best conductors of heat.

Experiment.—Take a number of straight wires, of equal diameters and lengths, but of different metals; for instance, gold, silver, copper, iron, &c.; cover each of them with a thin coat of wax, or tallow, and plunge their extremities into water, kept boiling, or into melted lead. The melting of the coat of wax will show that caloric is more quickly transmitted through some metals than others.

It is on this account also, that the end of a glass rod may be kept red-hot for a long time, or even melted, without any inconvenience to the hand which holds the other extremity; though a similar metallic rod, heated in the same manner, would very soon become too hot to be held.

Liquid and Aëriform Bodies convey Heat by an actual Change in the Situation of their Particles.

Count Rumford was the first who proved that fluids in general, and aëriform bodies, convey heat on a different principle from that observed in solids. This opinion is pretty generally admitted, though various ingenious experiments have been made by different philosophers to prove the contrary. In water, for instance, the Count has proved that caloric is propagated principally in consequence of the motion which is occasioned in the particles of that fluid.

All fluids are considered by him, strictly speaking, in a similar respect as *non-conductors* of caloric. They can receive it, indeed, from other substances, and can give it to other substances, but no particle can either receive it from or give it to another particle of the same kind. Before a fluid, therefore, can be heated or cooled, every particle must go individually to the substance from which it receives or to which it gives out caloric. Heat being, therefore, only propagated in fluids, in consequence of the internal motion of their particles, which transport the heat; the more rapid these motions are, the more rapid is the communication of heat. The cause of these motions is the change in the specific gravity of the fluid, occasioned by the change of temperature, and the rapidity is in proportion to the change of the specific gravity of the liquid by any given change of temperature. The following experiment may serve to illustrate this theory:

Take a thin glass tube, eight or ten inches long, and about an inch in diameter. Pour into the bottom part, for about the depth of one inch, a little water coloured with Brazil-wood, or litmus, and then fill up the tube with common water, extremely gently, so as to keep the two *strata* quite distinct from each other. Having done this, heat the bottom part of the tube over a lamp; the coloured infusion will then ascend, and gradually tinge the whole fluid; on the contrary, if the heat be applied above, the water in the upper part of the tube may be made to boil, but the colouring matter will remain at the bottom undisturbed. The heat cannot act downwards to make it ascend.

By thus being able to make the upper part of a fluid boil without heating the bottom part, water may be kept boiling for a considerable time in a glass tube over ice, without melting it.

Other experiments, illustrating the same principle, may be found in Count Rumford's excellent Essays, especially in Essay the 7th; 1797.

To this indefatigable philosopher we are wholly indebted for the above facts: he was the first who taught us that air and water were nearly non-conductors. The results of his experiments, which are contained in the above Essay, are highly interesting; they also show that the conducting power of fluids is impaired by the admixture of fibrous and glutinous matter.

Count Rumford proved that ice melted more than 80 times slower, when boiling-hot water stood on its surface, than when the ice was placed to swim on the surface of the hot water. Other experiments showed that water, only eight degrees of Fahrenheit above the freezing point, or at the temperature of forty degrees, melts as much ice, in any given time, as an equal volume of that fluid at any higher temperature, provided the water stands on the surface of the ice. Water, at the temperature of 41°, is found to melt more ice, when standing on its surface, than boiling water. It appears, however, that liquids are not, as he supposes, complete non-conductors of caloric; because if heat be applied at top, it is capable of making its way downwards, through water for example, though very imperfectly and slowly.

It becomes further evident, from the Count's ingenious experiments, that of the different substances used in clothing, hares' fur and eider-down are the warmest; next to these, beavers' fur, raw silk, sheep's wool, cotton wool, and lastly, lint, or the scrapings of fine linen. In fur, the air interposed among its particles is so engaged as not to be driven away by the heat communicated thereto by the animal body; not being easily displaced, it becomes a barrier to defend the animal body from the external cold. Hence it is obvious that those skins are warmest which have the finest, longest, and thickest fur; and that the furs of the beaver, otter, and other like quadrupeds, which live much in the water, and the feathers of water-fowl, are capable of confining the heat of those animals in winter, notwithstanding the coldness of the water which they frequent. Bears, and various other animals, inhabitants of cold climates, which do not often take the water, have their fur much thicker on their backs than on their bellies.

The snow which covers the surface of the earth in winter, in high latitudes, is doubtless designed as a garment to defend it against the piercing winds from the polar regions, which prevail during the cold season.

Without dwelling farther upon the philosophy of this truth, we must briefly remark that the happy application of this law, satisfactorily elucidates some of the most interesting facts of the economy of nature.

Theory of Caloric of Fluidity, or Latent Heat.

There are some bodies which, when submitted to the action of caloric, dilate to such a degree, and the power of aggregation subsisting among their particles is so much destroyed and removed to such a distance by the inteposition of caloric, that they slide over each other in every direction, and therefore appear in a fluid state. This phenomenon is called *fusion*. Bodies thus rendered fluid by means of caloric, are said to be *fused*, or *melted*; and those that are subject to it, are called *fusible*.

The greater number of solid bodies may, by the application of heat, be converted into fluids. Thus metals may be fused; sulphur, resin, phosphorus, may be melted; ice may be converted into water, &c.

Those bodies which cannot be rendered fluid by any degree of heat hitherto known, are called *infusible*.

If the effects of heat under certain circumstances, be carried still further than is necessary to render bodies fluid, vaporization begins; the bodies then become converted into the vaporous or *gaseous state*. Vaporization, however, does not always require a previous fusion. Some bodies are capable of being converted into the vaporous state, without previously becoming fluid, and others cannot be volatilized at any temperature hitherto known: the latter are termed fixed.

Fluidity is therefore by no means essential to any species of matter, but always depends on the presence of a quantity of caloric. Solidity is the natural state of all bodies, and there can be no doubt that every fluid is capable of being rendered solid by a due reduction of temperature; and every solid may be fused by the agency of caloric, if the latter does not decompose them at a temperature inferior to that which would be necessary for their fusion.

Caloric of Fluidity.

Dr. Black was the first who proved that, whenever caloric combines with a solid body, the body becomes heated only, until it is rendered fluid: and that, while it is acquiring the fluid state, its temperature remains stationary, though caloric is continued to be added to it. The same is the case when fluids are converted into the aëriform or vaporous state.

From these facts the laws of latent heat have been inferred. The theory may be illustrated by means of the following experiments.

If a lump of ice, at a low temperature, suppose at 22°, be brought into a warm room, it will become gradually less cold, as may be discovered by means of the thermometer. After a very short time, it will reach the temperature of 32°, (the freezing point;) but there it stops. The ice then begins to melt; but the process goes on very slowly. During the whole of that time its temperature continues at 32°; and as it is constantly surrounded by warm air, we have reason to believe that caloric is constantly entering into it; yet it does not become hotter till it is changed into water. Ice, therefore, is converted into water by a quantity of caloric uniting with it.

It has been found by calculation, that ice in melting absorbs 140° of caloric, the temperature of the water produced still remaining at 32°.

This fact may be proved in a direct manner.

Take one pound of ice, at 32°, reduced to a coarse powder; put it into a wooden bowl, and pour over it one pound of water, heated to 172°; all the ice will become melted, and the temperature of the whole fluid, if examined by a thermometer, will be 32°; 140° of caloric are therefore lost, and it is this quantity which was requisite to convert the ice into water. This experiment succeeds better, if, instead of ice, fresh fallen snow be employed.

This caloric has been called *latent caloric*, because its presence is not measurable by the thermometer: also more properly caloric of fluidity.

Dr. Black has also ascertained by experiment, that the fluidity of melted wax, tallow, spermaceti, metals, &c. is owing to the same cause; and Landriani proved, that this is the case with sulphur, alum, nitrate of potassa, &c.

We consider it therefore as a general law, that whenever a solid is converted into a fluid, it combines with caloric, and that is the cause of fluidity.

Conversion of Solids and Fluids into the Aëriform or Gaseous State.

We have seen before, that, in order to render solids fluid, a certain quantity of caloric is necessary, which combines with the body, and therefore cannot be measured by the thermometer; we shall now endeavour to prove, that the same holds good in respect to the conversion of solids or fluids into the vaporous or gaseous state.

Take a small quantity of carbonate of ammonia, introduce it into a retort, the neck of which is directed under a cylinder filled with mercury and inverted in a bason of the same fluid. On applying heat to the body of the retort, the carbonate of ammonia will be volatilized, it will expel the mercury out of the cylinder, and become an invisible gas, and would remain so, if its temperature was not lowered.

The same is the case with benzoic acid, camphire, and various other substances.

All fluids may, by the application of heat, be converted into an aëriform elastic state.

When we consider water in a boiling state, we find that this fluid, when examined by the thermometer, is not hotter after boiling several hours, than when it began to boil, though to maintain it boiling a brisk fire must necessarily be kept up. What then, we may ask, becomes of the wasted caloric? It is not perceptible in the water, nor is it manifested by the steam; for the steam, if not compressed, upon examination, is found not to be hotter than boiling water. The caloric is therefore absorbed by the steam, and although what is so absorbed, is absolutely necessary for the conversion of water into the form of steam; it does not increase its temperature, and is therefore not appreciable by the thermometer.

The conclusion is further strengthened by the heat given out by steam on its being condensed by cold. This is particularly manifested in the condensation of this fluid in the process of distilling, where, upon examining the refrigeratory, it will be found that a much greater quantity of caloric is communicated to it, than could possibly have been transmitted by the caloric which was sensibly acting before the condensation. This may be easily ascertained by observing the quantity of caloric communicated to the water in the refrigeratory of a still, by any given quantity of liquid that passes over.

1. The boiling point, or the temperature at which the conversion of fluids into gases takes place, is different in different fluids, but constant in each, provided the pressure of the atmosphere be the same.

Put any quantity of sulphuric æther into a Florence flask, suspend a thermometer in it, and hold the flask over an Argand's lamp, the æther will immediately begin to boil, and the thermometer will indicate 98°, if the æther has been highly rectified.

If highly rectified ardent spirit is heated in a similar manner, the thermometer will rise to 176°, and there remain stationary.

If water is substituted, it will rise to 212°.

If strong nitrous acid of commerce be made use of, it will be found to boil at 248°;—sulphuric acid and linseed-oil at 600°;—mercury at 656°, &c.

2. The boiling point of fluids is raised by pressure.

Mr. Watt heated water under a strong pressure to 400°. Yet still when the pressure was removed, only part of the water was converted into vapour, and the temperature of this vapour, as well as that of the remaining fluid, was no more than 212°. There was therefore 188° of caloric suddenly lost. This caloric was carried off by the steam. Now as only about one-fifth of the water was converted into steam, that steam must contain not only its own 188°, but also the 188° lost by each of the other four parts; that is to say, it must contain 188° × 5, or about 940°. Steam, therefore, is water combined with at least 940° of caloric, the presence of which is not indicated by the thermometer.

3. When pressure is removed from the surface of bodies, their conversion into the gaseous state is greatly facilitated, or their boiling point is lowered.

In proof of this the following experiments may serve:

Let a small bottle be filled with highly rectified sulphuric æther, and a piece of wetted bladder be tied over its orifice around its neck. Transfer it under the receiver of an air-pump, and take away the superincumbent pressure of the air in the receiver. When the exhaustion is complete, pierce the bladder by means of a pointed sliding wire, passing through a collar of leather which covers the upper opening of the receiver. Having done this, the æther will instantly begin to boil, and become converted into an invisible gaseous fluid.

Take a small retort or Florence flask, fill it one half or less with water, and make it boil over a lamp; when kept briskly boiling for about five minutes, cork the mouth of the retort as expeditiously as possible, and remove it from the lamp.

The water, on being removed from the source of heat, will keep boiling for a few minutes, and when the ebullition begins to slacken, it may be renewed by dipping the retort into cold water, or pouring cold water upon it.

The water, during boiling, becomes converted into vapour; this vapour expels the air of the vessel, and occupies its place; on diminishing the heat, it condenses; when the retort is stopped, a partial vacuum is formed; the pressure becomes diminished, and a less degree of heat is sufficient to cause an ebullition.

For the same reason, water may be made to boil under the exhausted receiver at 94° Fahr. or even at a lower degree; alkohol at 56°; and æther at —20°.

On the conversion of fluids into gases is founded the following experiment, by which water is frozen by means of sulphuric æther.

Take a thin glass tube four or five inches long and about two or three-eighths of an inch in diameter, and a two-ounce bottle furnished with a capillary tube fitted to its neck. In order to make ice, pour a little water into the tube, taking care not to wet the outside, nor to leave it moist. Having done this, let a stream of sulphuric æther fall through the capillary tube upon that part of it containing the water, which by this means will be converted into ice in a few minutes, and this it will do even near a fire or in the midst of summer.

If the glass tube, containing the water, be exposed to the brisk thorough air, or free draught of an open window, a large quantity of water may be frozen in a shorter time; and if a thin spiral wire be introduced previous to the congelation of the water, the ice will adhere to it, and may thus be drawn out conveniently.

A person might be easily frozen to death during very warm weather, by merely pouring upon his body for some time sulphuric æther, and keeping him exposed to a thorough draught of air.

Artificial Refrigeration.

The cooling or refrigeration of rooms in the summer season by sprinkling them with water, is on the principle of evaporation.

The method of making ice artificially in the East Indies depends on the same principle. The ice-makers at Benares dig pits in large open plains, the bottom of which they strew with sugar-canes or dried stems of maize or Indian-corn. Upon this bed they place a number of unglazed pans, made of so porous an earth that the water penetrates through their whole substance. These pans are filled towards evening in the winter season with water that has boiled, and left in that situation till morning, when more or less ice is found in them, according to the temperature and other qualities of the air; there being more formed in dry and warm weather, than in that which is cloudy, though it may be colder to the human body.

Every thing in this process is calculated to produce cold by evaporation; the beds on which the pans are placed, suffer the air to have a free passage to their bottoms; and the pans constantly oozing out water to their external surface, are cooled by the evaporation of it.

In Spain, they use a kind of earthen jars, called buxaros, which are only half-baked, the earth of which is so porous, that the outside is kept moist by the water which filters through it, and though placed in the sun, the water in the jar becomes as cold as ice.

It is a common practice in China to cool wine or other liquors by wrapping the bottle in a wet cloth, and hanging it up in the sun. The water in the cloth becomes converted into vapour, and thus cold is produced.

The Blacks in Senegambia have a similar method of cooling water by filling tanned leather bags with it, which they hang up in the sun; the water oozes, more or less through the leather so as to keep the outward surface wet, which by its quick and continued evaporation cools the water remarkably.

The winds on the borders of the Persian Gulph are often so scorching, that travellers are suddenly suffocated unless they cover their heads with a wet cloth; if this be too wet, they immediately feel an intolerable cold, which would prove fatal if the moisture was not speedily dissipated by the heat.

Condensation of Vapour.

If a cold vessel is brought into a warm room, particularly where many people are assembled, the outside of it will soon become covered with a sort of dew.

Before some changes of weather, the stone pavements, the walls of a house, the balustrades of staircases, and other solid objects, feel clammy and damp.

In frosty nights, when the air abroad is colder than the air within, the dampness of this air, for the same reason, settles on the glass panes of the windows, and is there frozen into curious and beautiful figures.

Thus *fogs* and *dews* take place, and in the higher regions clouds are formed from the condensed vapour. The still greater condensation produces *mists* and *rain*.

Capacity of Bodies for containing Heat.

The property which different bodies possess, of containing at the same temperature, and in equal quantities, either of mass or bulk, unequal quantities of heat, is called their capacity for heat. The capacities of bodies for heat are therefore considered as great or small in proportion as their temperatures are either raised by the addition, or diminished by the deprivation, of equal quantities of heat, in a less or a greater degree.

In homogeneous bodies, the quantities of caloric which they contain are in the ratio of their temperature and mass: when, therefore, equal quantities of water, of oil, or of mercury, of unequal temperatures, are mingled together, the temperature of the whole will be the *arithmetical* mean between the temperatures of the two quantities that had been mixed together. It is a self-evident truth that this should be the case, for the particles of different portions of the same substance being alike, their effects must be equal. For instance:

Mix a pound of water at 172° with a pound at 32°, half the excess of heat in the hot water will quit it to go over into the colder portion; thus the hot water will be cooled 70°, and the cold will receive 70° of temperature; therefore 172—70, or 32 + 70 = 102, will give the heat of the mixture. To attain the arithmetical mean very exactly, several precautions, however, are necessary.

When heterogeneous bodies of different temperatures are mixed together, the temperature produced is never the arithmetical mean of the two original temperatures.

In order to ascertain the comparative quantities of heat of different bodies, equal weights of them are mingled together; the experiments for this purpose being in general more easily executed than those by which they are compared from equal bulks.

Thus, if one pound of mercury heated to 110° Fahr., be added to one pound of water of 44°, the temperature of the blended fluids will not be changed to 77°, as it would be if the surplus of heat were divided among those fluids in the proportion of their quantities. It will be found, on examination, to be only 47°.

On the contrary, if the pound of mercury be heated to 44°, and the water to 110°, then, on stirring them together, the common temperature will be 107°.

Hence, if the quicksilver loses by this distribution 63° of caloric, an equal weight of water gains only 3° from this loss of 63° of heat. And, on the contrary, if the water loses 3°, the mercury gains 63°.

When, instead of comparing the quantities of caloric which equal *weights* of different bodies contain, we compare the quantities contained in equal *volumes*, we still find that an obvious difference takes place. Thus it is found by experiment, that the quantity of caloric necessary to raise the temperature of a given volume of water any number of degrees, is, to that necessary to raise an equal volume of mercury, the same number of degrees as 2 to 1. This is, therefore, the proportion between the comparative quantities of caloric which these two bodies contain, estimated by their volumes; and similar differences exist with respect to every other kind of matter.

From the nature of the experiments by which the quantities of caloric which bodies contain are ascertained, it is evident that we discover merely the *comparative*, not the *absolute* quantities. Hence water has been chosen as a standard, to which other bodies may be referred; its capacity is stated as the arbitrary term of 1000, and with this the capacities of other bodies are compared.

It need not be told that pains have been taken to estimate on these experiments that portion of heat which diffuses itself into the air, or into the vessel where the mercury and water are blended together. As however such valuations cannot be made with complete accuracy, the numbers stated above are only an approximation to truth.

Radiation of Caloric.

Caloric is thrown off or radiates from heated bodies in right lines, and moves through space with inconceivable velocity. It is retarded in its passage by atmospheric air, by colourless fluids, glass, and other transparent bodies.

If a glass mirror be placed before a fire, the mirror transmits the rays of light, but not the rays of heat.

If a plate of glass, talc, or a glass vessel filled with water be suddenly interposed between the fire and the eye, the rays of light pass through it, but the rays of caloric are considerably retarded in its passage; for no heat is perceived until the interposed substance is saturated with heat, or has reached its *maximum*. It then ceases to intercept the rays of caloric, and allows them to pass as freely as the rays of light.

It has been lately shown by Dr. Herschel, that the rays of caloric are refrangible, but less so than the rays of light; and the same philosopher has also proved by experiment, that it is not only the rays of caloric emitted by the sun, which are refrangible, but likewise the rays emitted by common fires, by candles, by heated iron, and even by hot water.

Whether the rays of caloric are differently refracted, in different mediums, has not yet been ascertained. We are certain, however, that they are refracted by all transparent bodies which have been employed as burning glasses.

The rays of caloric are also reflected by polished surfaces, in the same manner as the rays of light.

This was long ago noticed by Lambert, Saussure, Scheele, Pictet, and lately by Dr. Herschel.

Professor Pictet placed two concave metallic mirrors opposite to each other, at the distance of about twelve feet. When a hot body, an iron bullet for instance, was placed in the focus of the one, and a mercurial thermometer in that of the other, a substance radiated from the bullet; it passed with incalculable velocity through the air, it was reflected from the mirrors, it became concentrated, and influenced the thermometer placed in the focus, according to the degree of its concentration.

An iron ball two inches in diameter, heated so that it was not luminous in the dark, raised the thermometer not less than ten and a half degrees of Reaumur's scale, in six minutes.

A lighted candle occasioned a rise in the thermometer nearly the same.

A Florence flask containing two ounces and three drachms of boiling water, raised Fahrenheit's thermometer three degrees. He blackened the bulb of his thermometer, and found that it was more speedily influenced by the radiation than before, and that it rose to a greater height.

M. Pictet discovered another very singular fact; namely, the *apparent radiation* of cold. When, instead of a heated body, a Florence flask full of ice or snow is placed in the focus of one of the mirrors, the thermometer placed in the focus of the other immediately descends, and ascends again whenever the cold body is removed.

This phenomenon may be explained on the supposition, that from every body at every temperature caloric radiates, but in less quantity as the temperature is low; so that in the above experiment, the thermometer gives out more caloric by radiation, than it receives from the body in the opposite focus, and therefore its temperature is lowered. Or, as Pictet has supposed, when a number of bodies near to each other have the same temperature, there is no radiation of caloric, because in all of them it exists in a state of equal tension; but as soon as a body at an inferior temperature is introduced, the balance of tension is broken, and caloric begins to radiate from all of them, till the temperature of that body is raised to an equality with theirs. In the above experiment, therefore, the placing the snow or ice in the focus of the mirror causes the radiation of caloric *from* the thermometer and hence the diminution of temperature which it suffers.

These experiments have been since repeated by Dr. Young and Professor Davy, at the theatre of the Royal Institution. These gentlemen inflamed phosphorus by reflected caloric; and proved that the heat thus excited was very sensible to the organs of feeling.

It is therefore evident, that caloric is thrown off from bodies in rays, which are invisible, or incapable of exciting vision, but which are capable of exciting heat.

These invisible rays of caloric are propagated in right lines, with extreme velocity; and are capable of the laws of reflection and refraction.

The heating agency however is different in the different coloured rays of the prismatic spectrum. According to Dr. Herschel's experiments, it follows inversely the order of the refrangibility of the rays of light. The least refrangible possessing it in the greatest degree.

Sir Henry Englefield has lately made a series of experiments on the same subject, from which we learn, that a thermometer having its ball blackened, rose when placed in the *blue* ray of the prismatic spectrum in 3′ from 55° to 56°; in the *green*, in 3′ from 54° to 58°; in the *yellow*, in 3′ from 56° to 62°; in the *full red* in 2½′ from 56° to 72°; in the *confines of the red*, in 2½′ from 58° to 73½°; and *quite out of the visible light*, in 2½′ from 61° to 79°.

Between each of the observations, the thermometer was placed in the shade so long as to sink it below the heat to which it had risen in the preceding observation; of course, its rise above that point could only be the effect of the ray to which it was exposed. It was continued in the focus long after it had ceased to rise; therefore the heats given are the greatest effects of the several rays on the thermometer in each observation. A thermometer placed constantly in the shade near the apparatus, was found scarcely to vary during the experiments.

Sir Henry made other experiments with thermometers with naked balls, and with others whose balls were painted white, for which we refer the reader to the interesting paper of the Baronet, from which the above experiments are transcribed.

Production of Artificial Cold, by means of Frigorific Mixtures.

A number of experiments have been lately made by different philosophers, especially by Pepys, Walker, and Lowitz, in order to produce artificial cold. And as these methods are often employed in chemistry, with a view to expose bodies to the influence of very low temperatures, we shall enumerate in a tabular form on next page the different substances which may be made use of for that purpose, and the degrees of cold which they are capable of producing.

To produce the effects stated in the table, the salts must be reduced to powder, and contain their full quantity of water of crystallization. The vessel in which the freezing mixture is made, should be very thin, and just large enough to hold it, and the materials should be mixed together as expeditiously as possible, taking care to stir the mixture at the same time with a rod of glass or wood.

In order to obtain the full effect, the materials ought to be first cooled to the temperature marked in *the table*, by introducing them into some of the other frigorific mixtures, and then mingling them together in a similar mixture. If, for instance, we wish to produce —46°, the snow and diluted nitric acid ought to be cooled down to 0°, by putting the vessel which contains each of them into the fifth freezing mixture in the above table, before they are mingled together. If a more intense cold be required, the materials to produce it are to be brought to the proper temperature by being previously placed in the second freezing mixture.

This process is to be continued till the required degree of cold has been procured.

A TABLE OF FREEZING MIXTURES.

Mixtures.	*Thermometer Sinks.*
Muriate of ammonia 5 parts Nitrate of potassa 5 Water 16	From 50° to 10°.
Muriate of ammonia 5 parts Nitrate of potassa 5 Sulphate of soda 8 Water 16	From 50° to 4°.
Sulphate of soda 3 parts Diluted nitric acid 2	From 50° to —3°.
Sulphate of soda 8 parts Muriatic acid 5	From 50° to 0°.
Snow 1 part Muriatic of soda 1	From 32° to 0°.
Snow or pounded ice 2 parts Muriate of soda 1	From 0° to —5°.
Snow or pounded ice 12 parts Muriate of soda 5 Muriate of ammonia and nitrate of potassa 5	From —5° to —18°.
Snow or pounded ice 12 parts Muriate of soda 5 Nitrate of ammonia 5	From —18° to —25°.
Snow 3 parts Diluted nitric acid 2	From 0° to —46°.
Muriate of lime 3 parts Snow 2	From 32° to —50°.
Potassa 4 parts Snow 3	From 32° to —51°.
Snow 8 parts Diluted sulphuric acid 3 Diluted nitric acid 3	From —10° to —56°.
Snow 1 part Diluted sulphuric acid 1	From 20° to —60°.
Muriate of lime 2 parts Snow 1	From 0° to —66°.
Muriate of lime 3 parts Snow 1	From —40° to —73°.
Diluted sulphuric acid 10 parts Snow 8	From —68° to —91°.
Nitrate of ammonia 1 part Water 1	From 50° to 4°.
Nitrate of ammonia 1 part Carbonate of soda 1 Water 1	From 50° to —7°.
Sulphate of soda 6 parts Muriate of ammonia 4 Nitrate of potassa 2 Diluted nitric acid 4	From 50° to —10°.
Sulphate of soda 6 parts Nitrate of ammonia 5 Diluted nitric acid 4	From 50° to —14°.
Phosphate of soda 9 parts Diluted nitric acid 4	From 50° to —12°.
Phosphate of soda 9 parts Nitrate of ammonia 6 Diluted nitric acid 4	From 50° to —21°.
Sulphate of soda 5 parts Diluted sulphuric acid 4	From 50° to 3°.

CALORI'METER. An instrument by which the whole quantity of absolute heat existing in a body in chemical union can be ascertained.

CALP. An argillo-ferruginous lime stone.

CA'LTHA. (Καλθα, corrupted from χαλχα, yellow; from whence, says Vossius, come *calthula, caldula, caledula, calendula.*) The marigold. 1. The name of a genus of plants in the Linnæan system. Class, *Polyandria*; Order, *Polygynia.*

2. The pharmacopœial name of the herb wild marigold, so called from its colour.

Caltha arvensis. *Calendula arvensis; Caltha vulgaris.* The wild marigold is sometimes preferred to the garden marigold. Its juice is given, from one to four ounces, in jaundice and cachexia; and the leaves are commended as a salad for children afflicted with scrophulous humours.

Caltha palustris. *Populago.* Common single marsh marigold. It is said to be caustic and deleterious: but this may be questioned. The young buds of this plant make, when properly pickled, very good substitutes for capers.

Caltha vulgaris. See *Caltha arvensis.*

Ca'lthula. The caltha is so called.

CALTROPS. See *Trapa natans.*

CALU'MBA. The name now adopted by the London college of physicians for the root of the *Cocculus palmatus* of De Candolles, in his *Systema naturæ.* It was formerly called *Colombo; Calomba;* and *Colamba.* This root is imported from Colomba, in Ceylon, in circular, brown knobs, wrinkled on their outer surface, yellowish within, and consisting of cortical, woody, and medullary laminæ. Its smell is aromatic; its taste pungent, and very bitter. From Dr. Percival's experiments on the root, it appears that rectified spirit of wine extracts its virtues in the greatest perfection. The watery infusion is more perishable than that of other bitters. An ounce of the powdered root, half an ounce of orange-peel, two ounces of brandy, and fourteen ounces of water, macerated twelve hours without heat, and then filtered through paper, afford a sufficiently strong and tolerably pleasant infusion. The extract made first by spirit and then with water, and reduced by evaporation to a pillular consistence, is found to be equal, if not superior in efficacy, to the powder. As an antiseptic, Calumba root is inferior to the bark; but, as a corrector of putrid bile, it is much superior to the bark; whence also it is probable, that it would be of service in the West-India yellow fever. It also restrains alimentary fermentation, without impairing digestion; in which property it resembles mustard. It does not appear to have the least heating quality, and therefore may be used in phthisis pulmonalis, and in hectic cases, to strengthen digestion. It occasions no disturbance, and agrees very well with a milk diet, as it abates flatulence, and is indisposed to acidity. The London, Edinburgh, and Dublin colleges, direct a tincture of Calumba root. The dose of the powdered root is as far as half a drachm, which, in urgent cases, may be repeated every third or fourth hour.

CA'LVA. (From *calvus,* bald.) The scalp or upper part of the cranium or top of the head; so called because it often grows bald first.

CALVA'RIA. (From *calvus,* bald.) The upper part of the cranium which becomes soon bald. It comprehends all above the orbits, temples, ears, and occipital eminence.

CALVI'TIES. (From *calvus,* bald.) *Calvitium.* Baldness; want or loss of hair, particularly upon the sinciput.

This name is applied by Dr. Good to a species of his *trichosis athrix,* or baldness.

CALX. (*Calx, cis.* fœm.; from *kalah,* to burn. Arabian.) 1. Chalk. Limestone.

2. Lime. *Calx viva.* The London College directs it to be prepared thus:—Take of limestone one pound: break it into small pieces, and heat it in a crucible, in a strong fire, for an hour, or until the carbonic acid is entirely driven off, so that on the addition of acetic acid, no bubbles of gas shall be extricated. Lime may be made by the same process from oyster-shells previously washed in boiling water and cleared from extraneous matters. See *Lime.*

Calx antimonii. See *Antimonii oxydum.*

Calx cum kali puro. See *Potassa cum calce.*

Calx hydrargyri alba. See *Hydrargyrum præcipitatum album.*

Calx metallic. A metal which has undergone the process of calcination, or combustion, or any other equivalent operation.

Calx viva. See *Calx.*

Calycanthemæ. (From *calyx,* the flower-cup, and ανθος, the flower.) The name of an order in Linnæus's fragments of a natural method, consisting of plants, which, among other characteristics have the corolla and stamina inserted into the calyx.

CALYCIFLORÆ. (From *calyx,* and *flos,* a flower.) The name of an order in Linnæus's fragments of a natural method, consisting of plants which have the stamina inserted into the calyx.

CALYCINUS. (From *calyx,* the flower-cup.) *Calycinalis.* Belonging to the calyx of a flower; applied to the nectary, *nectarium calycinum,* it being a production of the calyx; as in *Tropæolum majus,* the garden nasturtium.

CALYCULATUS. (From *calyculus,* a small calyx.) Calyculate. Applied to a *perianthium* when there are lesser ones, like scales, about its base; as in *Dianthus caryophyllus. Semina calyculata* are those which are enclosed in a hard bone-like calyx, as those of the *Coix lachryma,* or Job's tears.

CALYCULUS. (Diminutive of *calyx.*) A little calyx. A botanical term for

I. The membranaceous margin surrounding the apex of a seed.

The *varieties* are,

1. *Calyculus integer,* the margin perfect not incised; as in *Tanacetum vulgare,* and *Dipsacus laciniatus.*

2. *Calyculus palyaceus,* with chaffy scales; as in *Helianthus annuus.*

3. *Calyculus aristatus,* having two or three awns at the top; as in *Tagetes patula,* and *Bidens tripartita.*

4. *Calyculus rostratus,* the style of the germ remaining; as in *Sinapis,* and *Scandix cerefolium.*

5. *Calyculus cornutus,* horned, the rostrum bent; as in *Nigella damascena.*

6. *Calyculus cristatus,* a dentate, or incised membrane on the top of the seed; as in *Hedysarum crista galli.*

II. A little calyx exterior to another proper one.

Caly'pter. (From καλυπτω, to hide.) A carneous excrescence covering the hæmorrhoidal vein.

CALYPTRA. (From καλυπτω to cover.) I. The veil, or covering of mosses. A kind of membraneous hood placed, on their capsule or fructification, like an extinguisher on a candle, well seen in *Bryum cæspitosum.* Linnæus considered it as a calyx, but other botanists, especially Schreber and Smith, reckon it to be a sort of corolla. It is either,

1. *Acuminate,* pointed; as in *Minium* and *Bryum.*

2. *Caducous,* falling off yearly as in *Bauxbaumia.*

3. *Conical;* as in most mosses.

4. *Smooth;* as in *Hypnum.*

5. *Lævis,* without any inequalities; as in *Splanchnum.*

6. *Oblong;* as in *Minium.*

7. *Villous;* as in *Polytrichum.*

8. *Complete*, surrounding the whole of the top of the capsule.

9. *Dimidiate*, covering only half the capsule; as in *Bryum androgynum.*

10. *Dentate*, toothed in the margin; as in *Eucalypta ciliata.*

In many genera it is wanting.

II. The name in Tournefort, and writings of former botanists, for the proper exterior covering or coat of the seed, which falls off spontaneously.

CALYPTRATUS. (From *calyptra*, the veil, or covering of mosses.) Calyptrate: having a covering like the calyptra of mosses.

CALYX. (*Calyx, icis.* f.; *καλυξ*; from *καλυπτω*, to cover.) *Calix.* I. The flower-cup, or, more correctly, the external covering of the flower, for the most part green, and surrounding the corolla, or gaudy part.

There are five *genera* of calyces, or flower-cups.

1. *Perianthium*
2. *Involucrum.*
3. *Amentum*
4. *Spatha.*
5. *Gluma*
6. *Perichætium.*
7. *Volva.*

II. The membrane which covers the papillæ in the pelvis of the human kidney.

CA'MARA. (From *καμαρα*, a vault.) *Camarium.* 1. The fornix of the brain.

2. The vaulted part of the auricle of the heart.

CAMA'RIUM. (From *καμαρα*, a vault.) A vault. See *Camara.*

CAMARO'MA. (From *καμαρα*, a vault.) *Camarosis; Camaratio.* A fracture of the skull, in the shape of an arch or vault.

CAMBIREA. So Paracelsus calls the venereal bubo.

CA'MBIUM. The gelatinous substance, or matter of organisation which Du Hamel and Mirbel suppose produces the young bark, and new wood of plants.

CAMBIUM. (From *cambio*, to exchange.) The nutritious humour which is changed into the materials of which the body is composed.

CAMBO'DIA. See *Stalagmitis.*

CAMBO'GIA. (From the province of *Cambaya*, in the East Indies;) *Cambodja* and *Cambogia: Cambodia; Cambogium; Gambogia; Gambogium.* See *Stalagmitis.*

CAMBOGIA GUTTA. See *Stalagmitis.*

CAMBO'GIUM. See *Cambogia* and *Stalagmitis.*

CAMBRO-BRITANNICA. See *Rubus Chamæmorus.*

CAMBU'CA. *Cambuta membrata.* So Paracelsus calls the venereal cancer. By some it is described as a bubo, an ulcer, an abscess on the pudenda; also a boil in the groin.

CA'MBUI. The wild American myrtle of Piso and Margrave, which is said to be astringent.

Camel's hay. See *Andropogon Schœnanthus.*

CAMELEON MINERAL. When pure potassa and black oxide of manganese are fused together in a crucible, a compound is formed, whose solution in water, at first green, passes spontaneously through the whole series of coloured rays to the red. From this latter tint, the solution may be made to retrograde in colour to the original green, by the addition of potassa; or it may be rendered altogether colourless, by adding either sulphureous acid or chlorine to the solution, in which case there may or may not be a precipitate, according to circumstances.

CA'MERA. A chamber or cavity. The chambers of the eye are termed *cameræ.*

CAMERA'TIO. See *Camaroma.*

CA'MES. *Camet.* Silver.

CAMI'NGA. See *Canella alba.*

CA'MINUS. A furnace and its chimney. In Rulandus it signifies a bell.

CAMI'SIA FŒTUS. (From the Arabic term *kamisah*, an under garment.) The shirt of the fœtus. See *Chorion.*

Camomile. See *Chamomile.*

CAMOMI'LLA. Corrupted from *chamæmelum.*

CA'MMORUM. (*Καμμορον, quia homines, κακῳ μορῳ, perimat*; because if eaten, it brings men to a miserable end.) A species of monkshood. See *Aconitum napellus.*

CAMPA'NA. A bell. In chemistry, a receptacle like a bell, for making sulphuric acid; thus the oleum sulphuris per campanum.

CAMPANACEÆ. Bell-shaped flowers. The name of an order of Linnæus's natural method.

CAMPANIFORMIS. *Campanaceus; Campanulatus.* Bell-shaped; applied to the corolla and nectaries of plants.

CAMPA'NULA. (From *campana*, a bell; named from its shape.) The name of a genus of plants in the Linnæan system. Class, *Pentandria*; Order, *Monogynia.* The bell-flower.

CAMPANULA TRACHELEUM. *Cervicaria.* The Great Throat-wort: by some recommended against inflammatory affections of the throat and mouth.

CAMPAN'ULATUS. (From *Campanula*, a little bell.) Bell-shaped: applied to the corolla and nectary of plants, as in *Campanula.* See *Carolla* and *Nectarium.*

CA'MPE. (From *καμπτω*, to bend.) A flexure or bending. It is also used for the ham, and a joint, or articulation.

Campeachy wood. See *Hæmatoxylon Campechianum.*

CAMPECHE'NSE LIGNUM. See *Hæmatoxylon Campechianum.*

CAMPER, PETER, was born at Leyden in 1722, where he studied under Boerhaave, and took his degree in medicine. He then travelled for some years, and was afterwards appointed a professor successively at Franeker, Amsterdam, and Groningen. He was subsequently occupied in prosecuting his favourite studies, in visiting various parts of Europe, by the different societies of which he was honourably distinguished, and in performing many public duties in his own country, being at length chosen one of the council of state. He died in 1789 of a pleurisy. He published some improvements in midwifery and surgery, but anatomy appears to have been his favourite pursuit. He finished two parts of a work of considerable magnitude and importance, in which the healthy and morbid structure of the arm, and of the pelvis, are exhibited in very accurate plates, from drawings made by himself: which he appears to have purposed extending to the other parts of the body. There are also some posthumous works of Camper possessing great merit, partly on subjects of natural history, partly evincing the connexion between anatomy and painting; in which latter judicious rules are laid down for exhibiting the diversity of features in persons of various countries and ages, and representing the different emotions of the mind in the countenance; also for delineating the general forms of other animals, which he shows to be modified according to their economy.

CAMPESTRIS. Of or belonging to the field: applied as a trivial name to many plants, which are common in the fields.

CAMPHIRE. See *Laurus camphora.*

Camphor. See *Laurus camphora.*

CA'MPHORA. (*Camphura.* Arabian. The ancients meant by camphor what now is called asphaltum, or Jews' pitch; καφουρα.) See *Laurus camphora.*

CA′MPHORÆ FLORES. The subtle substance which first ascends in subliming camphor. It is nothing more than the camphor.

CAMPHORÆ FLORES COMPOSITI. Camphor sublimed with benzoin.

CA′MPHORAS. A camphorate. A salt formed by the union of the camphoric acid with a salifiable base; thus, *camphorate of alumine, camphorate of ammonia,* &c.

CAMPHORA′SMA. (From *camphora;* so called from its camphor-like smell.) Turkey balsam. See *Dracocephalum.*

CAMPHORA′TA. See *Camphorosma.*

CAMPHORA′TUM OLEUM. See *Linimentum camphoræ.*

CAMPHORIC ACID. *Acidum camphoricum.* An acid with peculiar properties is obtained, by distilling nitric acid eight times following from camphor; and the following is the account Bouillon Lagrange gives of its preparation and properties.

One part of camphor being introduced into a glass retort, four parts of nitric acid of the strength of 36 degrees are to be poured on it, a receiver adapted to the retort, and all the joints well luted. The retort is then to be placed on a sand-heat, and gradually heated. During the process a considerable quantity of nitrous gas, and of carbonic acid gas, is evolved; and part of the camphor is volatilised, while another part seizes the oxygen of the nitric acid. When no more vapours are extricated, the vessels are to be separated, and the sublime camphor added to the acid that remains in the retort. A like quantity of nitric acid is again to be poured on this, and the distillation repeated. This operation must be reiterated till the camphor is completely acidified. Twenty parts of nitric acid at 36 are sufficient to acidify one of camphor.

When the whole of the camphor is acidified, it crystallises in the remaining liquor. The whole is then to be poured out upon a filter, and washed with distilled water, to carry off the nitric acid it may have retained. The most certain indication of the acidification of the camphor is its crystallizing on the cooling of the liquor remaining in the retort. To purify this acid it must be dissolved in hot distilled water, and the solution, after being filtered, evaporated nearly to half, or till a slight pellicle forms; when the camphoric acid will be obtained in crystals on cooling.

The camphoric acid has a slightly acid, bitter taste, and reddens infusion of litmus.

It crystallises; and the crystals upon the whole resemble those of muriate of ammonia. It effloresces on exposure to the atmosphere; is not very soluble in cold water; when placed on burning coals, it gives out a thick aromatic smoke, and is entirely dissipated; and with a gentle heat melts, and is sublimed. The mineral acids dissolve it entirely. It decomposes the sulphate and muriate of iron. The fixed and volatile oils dissolve it. It is likewise soluble in alkohol, and is not precipitated from it by water; a property that distinguishes it from the benzoic acid. It unites easily with the earths and alkalies, and forms camphoratis.

To prepare the *camphorates of lime, magnesia,* and *alumina,* these earths must be diffused in water, and crystallised camphoric acid added. The mixture must then be boiled, filtered while hot, and the solution concentrated by evaporation.

The *camphorate of barytes* is prepared by dissolving the pure earth in water, and then adding crystallised camphoric acid.

Those of *potassa, soda,* and *ammonia,* should be prepared with their carbonates dissolved in water: these solutions are to be saturated with crystallised camphoric acid, heated, filtered, evaporated, and cooled; by which means the camphorates will be obtained.

If the camphoric acid be very pure, they have no smell; if it be not, they have always a slight smell of camphor.

The *camphorates of alumina* and *barytes* leave a little acidity on the tongue; the rest have a slightly bitterish taste.

They are all decomposed by heat; the acid being separated and sublimed, and the base remaining pure; that of ammonia excepted, which is entirely volatilized.

If they be exposed to the blowpipe, the acid burns with a blue flame: that of ammonia gives first a blue flame; but toward the end it becomes red.

The *camphorates of lime* and *magnesia* are little soluble, the others dissolve more easily.

The mineral acids decompose them all. The alkalies and earths act in the order of their affinity for the camphoric acid; which is, lime, potassa, soda, barytes, ammonia, alumina, magnesia.

Several metallic solutions, and several neutral salts, decompose the camphorates; such as the nitrate of barytes, most of the calcareous salts, &c.

The camphorates of lime, magnesia, and barytes, part with their acid to alkohol.—*Lagrange's Manuel d'un Cours de Chimie.*

CAMPHORO′SMA. (From *camphora,* and οσμη, smell; so called from its smelling of camphire.) The camphor-smelling plant.

1. The name of a genus of plants in the Linnæan system. Class, *Tetandria;* Order, *Monogynia.*

2. The pharmacopœial name of the camphorata. See *Camphorosma Monspeliensis.*

CAMPHOROSMA MONSPELIENSIS. The systematic name of the plant called *camphorata* in the pharmacopœias. *Chamæpeuce—Camphorata hirsuta—Camphorosma Monspeliaca.* Stinking ground-pine. This plant, *Camphorosma—foliis hirsutis linearibus,* of Linnæus, took its name from its smell resembling so strongly that of camphor: it has been exhibited internally, in form of decoction, in dropsical and asthmatic complaints, and by some is esteemed in fomentations against pain. It is rarely, if ever, used in modern practice.

CA′MPTER. (From καμπτω, to bend.) An inflexion or incurvation.

CA′MPULUM. (From καμπτω, to twist about.) A distortion of the eyelids or other parts.

CAMPYLO′TIS. (From καμπυλος, bent.) A preternatural incurvation, or recurvation of a part; also a distortion of the eyelids.

CA′MPYLUM. See *Campylotis.*

CA′NABIL. A sort of medicinal earth.

CANABI′NA AQUATICA. See *Bidens.*

CA′NABIS INDICA. See *Bangue* and *Cannabis.*

CANABIS PEREGRINA. See *Cannabis.*

Ca′nada balsam. See *Pinus balsamea.*

Canada maidenhair. See *Adianthum pedatum.*

CANADE′NSIS. (Brought from *Canada.*) Canadian. A name of a balsam. See *Pinus balsamea.*

CANALICULATUS. Channelled; having a long furrow; applied to leaves, pods, &c. See *Leaf* and *Legumen.*

CANALI′CULUS. (Diminutive of *canalis,*

a channel. A little canal. See *Canalis arteriosus*.

CANA'LIS. (From χανος, an aperture, or rather from *canna*, a reed.) A canal.

1. Specifically applied to many parts of the body; as *canalis nasalis*, &c.

2. The hollow of the spine.

3. A hollow round instrument like a reed, for embracing and holding a broken limb.

CANALIS ARTERIOSUS. *Canaliculus arteriosus; Canalis botalii.* A blood-vessel peculiar to the fœtus, disappearing after birth; through which the blood passes from the pulmonary artery into the aorta.

CANALIS NASALIS. A canal going from the internal canthus of the eye downwards into the nose: it is situated in the superior maxillary bone, and is lined with the pituitary membrane continued from the nose.

CANALIS PETITIANUS. A triangular cavity, naturally containing a moisture between the two laminæ of the hyaloid membrane of the eye, in the anterior part, formed by the separation of the anterior lamina from the posterior. It is named after its discoverer, M. Petit.

CANALIS SEMICIRCULARIS. Semicircular canal. There are three in each ear placed in the posterior part of the labyrinth. They open by five orifices into the vestibulum. See *Ear*.

CANALIS SEMISPETROS. The half bony canal of the ear.

CANALIS VENOSUS. A canal peculiar to the fœtus, disappearing after birth, that conveys the maternal blood from the *porta* of the liver to the ascending *vena cava*.

Cana'ry balm. See *Dracocephalum*.

CA'NCAMUM GRÆCORUM. See *Hymenæa Courbaril*.

CANCELLATUS. Having the reticulated appearance of the *cancelli* of bones.

CANCE'LLI. Lattice-work; applied to the reticular substance in bones.

CANCE'LLUS. (From *cancer*, a crab.) A species of cray-fish, called Bernard the hermit and the wrong heir; the *Cancer cancellus* of Linnæus; supposed to cure rheumatism, if rubbed on the part.

CA'NCER. 1. The common name of the crab-fish. See *Cancer Astacus*.

2. The name of a disease, from καρκινος, a crab; so called by the ancients, because it exhibited large blue veins like crab's claws: likewise called *Carcinoma*, *Carcinos*, by the Greeks, *Lupus* by the Romans, because it eats away the flesh like a wolf. Dr. Cullen places this genus of disease in the class *Locales*, and order *Tumores*. He defines it a painful scirrhous tumour, terminating in a fatal ulcer. Any part of the body may be the seat of cancer, though the glands are most subject to it. It is distinguished, according to its stages, into *occult* and *open*; by the former is meant its scirrhous state, which is a hard tumour that sometimes remains in a quiet state for many years. When the cancerous action commences in it, it is attended with frequent shooting pains: the skin that covers it, becomes discoloured, and ulceration sooner or later takes place: when the disease is denominated *open* cancer. Mr. Pearson says, "When a malignant scirrhus or a watery excrescence hath proceeded to a period of ulceration, attended with a constant sense of ardent and occasionally shooting pains, is irregular in its figure, and presents an unequal surface; if it discharges sordid, sanious, or fœtid matter; if the edges of the sore be thick, indurated, and often exquisitely painful, sometimes inverted, at other times retorted, and exhibit a serrated appearance; and should the ulcer in its progress be frequently attended with hæmorrhage, in consequence of the erosion of blood-vessels; there will be little hazard of mistake in calling it a cancerous ulcer." In men, a cancer most frequently seizes the tongue, mouth, or penis; in women, the breasts or the uterus, particularly about the cessation of their periodical discharges; and in children, the eyes. The following description of Scirrhus and Cancer, from the above writer, will serve to elucidate the subject. A hard unequal tumour that is indolent, and without any discoloration in the skin, is called a scirrhus; but when an itching is perceived in it, which is followed by a pricking, shooting, or lancinating pain, and a change of colour in the skin, it is usually denominated a cancer. It generally is small in the beginning, and increases gradually; but though the skin changes to a red or livid appearance, and the state of the tumour from an indolent to a painful one, it is sometimes very difficult to say when the scirrhus really becomes a cancer, the progress being quick or slow according to concurring causes. When the tumour is attended with a peculiar kind of burning, shooting pains, and the skin hath acquired the dusky purple or livid hue, it may then be deemed the malignant scirrhus or *confirmed cancer*. When thus far advanced in women's breasts, the tumour sometimes increases speedily to a great size, having a knotty unequal surface, more glands becoming obstructed, the nipple sinks in, turgid veins are conspicuous, ramifying around, and resembling a crab's claws. These are the characteristics of an occult cancer on the external parts; and we may suspect the existence of one internally, when such pain and heat as has been described, succeed in parts where the patient hath before been sensible of a weight and pressure, attended with obtuse pain. A cancerous tumour never melts down in suppuration like an inflammatory one; but when it is ready to break open, especially in the breast, it generally becomes prominent in some minute point, attended with an increase of the peculiar kind of burning, shooting pain, felt before at intervals, in a less degree and deeper in the body of the gland. In the prominent part of the tumour, in this state, a corroding ichor sometimes transudes through the skin, soon forming an ulcer: at other times a considerable quantity of a thin lymphatic fluid tinged with blood from eroded vessels is found on it. Ulcers of the cancerous nature discharge a thin, fœtid, acrid sanies, which corrodes the parts, having thick, dark-coloured retorted lips; and fungous excrescences frequently rise from these ulcers, notwithstanding the corrosiveness of the discharge. In this state they are often attended with excruciating, pungent, lancinating, burning pains, and sometimes with bleeding.

Though a scirrhus may truly be deemed a cancer, as soon as pain is perceived in it, yet every painful tumour is not a cancer; nor is it always easy to say whether a cancer is the disorder or not. Irregular hard lumps may be perceived in the breast; but on examining the other breast, where no uneasiness is perceived, the same kind of tumours are sometimes found, which renders the diagnostic uncertain. Yet in every case after the cessation of the catamenia, hard unequal tumours in the breast are suspicious; nor, though without pain, are they to be supposed indolent or innoxious.

In the treatment of this disease, our chief reliance must be on extirpating the part affected. Some have attempted to dispel the scirrhous tumour by leeches and various discutient applications, to destroy it by caustics, or to check its progress by narcotics; but without material success. Certainly, before the disease is confirmed, should any inflammatory tendency appear, antiphlogistic means may be employed with propriety; but afterwards the operation should not be delayed: nay, where the nature of the tumour is doubtful, it will be better to remove it, than incur the risk of this dreadful disease. Some surgeons, indeed, have contested the utility of the operation; and no doubt the disease will sometimes appear again; from constitutional tendency, or from the whole not having been removed: but the balance of evidence is in favour of the operation being successful, if performed early, and to an adequate extent. The plan of destroying the part by caustic is much more tedious, painful, and uncertain. When the disease has arisen from some accident, not spontaneously, when the patient is otherwise healthy, when no symptoms of malignancy in the cancer have appeared, and the adjacent glands and absorbents seem unaffected, we have stronger expectation of success: but unless all the morbid parts can be removed without the risk of dividing important nerves or arteries, it should scarcely be attempted. In operating it is advisable; 1. To make the external wound sufficiently large, and nearly in the direction of the subjacent muscular fibres. 2. To save skin enough to cover it, unlesss diseased. 3. To tie every vessel which might endanger subsequent hæmorrhage. 4. To keep the lips of the wound in contact, not interposing any dressing, &c. 5. To preserve the parts in an easy and steady position for some days, before they are inspected. 6. To use only mild and cooling applications during the cure. Supposing, however, the patient will not consent to an operation, or circumstances render it inadmissible, the uterus, for example, being affected, internal remedies may somewhat retard its progress, or alleviate the sufferings of the patient: those, which have appeared most beneficial, are, 1. Arsenic, in very small doses long continued. 2. Conium, in doses progressively increased to a considerable extent. 3. Opium. 4. Belladonna. 5. Solanum. 6. Ferrum ammoniatum. 7. Hydrargyri oxymurias. 8. The juice of the galium aparine. When the part is external, topical applications may be useful to alleviate pain, cleanse the sore, or correct the fœtor; especially, 1. Fresh-bruised hemlock leaves. 2. Scraped young carrots. 3. The fermenting poultice. 4. Finely levigated chalk. 5. Powdered charcoal. 6. Carbonic acid gas, introduced into a bladder confined round the part. 7. A watery solution of opium. 8. Liquid tar, or tar-water. But none of these means can be relied upon for effecting a cure.

3. See *Carcinus.*

Cancer astacus. The systematic name of the crab-fish from which the claws are selected for medical use. Crab's claws and crab's eyes, as they are called, which are concretions found in the stomach, are of a calcareous quality, and possess antacid virtues. They are exhibited with their compounds in pyrosis, diarrhœa, and infantile convulsions from acidity.

Cancer cancellus. See *Cancellus.*

Cancer gammarus. The systematic name of the lobster.

Cancer munditorium. A peculiar ulceration of the scrotum of chimney-sweepers.

Ca'nchrys. Parched-barley.—*Galen.*

Cancre'na. Paracelsus uses this word instead of gangræna.

Cancro'rum chelæ. Crab's claws. See *Carbonas calcis*, and *Cancer astacus.*

Cancrorum oculi. See *Carbonas calcis*, and *Cancer astacus.*

CA'NCRUM. (From *cancer*, a spreading ulcer.) The canker.

Cancrum oris. Canker of the mouth; a fretted ulceration of the gums.

CANDE'LA. (From *candeo*, to shine.) A candle.

Candela fumalis. A candle made of odoriferous powders and resinous matters, to purify the air and excite the spirits.

Candela regia. See *Verbascum.*

Candela'ria. (From *candela*, a candle; so called from the resemblance of its stalks to a candle.) Mullein. See *Verbascum.*

Candy carrot. See *Athamanta cretensis.*

Cane'la. Sometimes used by the ancients for cinnamon, or rather cassia.

CANE'LLA. (*Canella*, diminutive of *canna*, a reed; so named because the pieces of bark are rolled up in the form of a reed.) The name of a genus of plants in the Linnæan system. Class, *Dodecandria*; Order, *Monogynia*. The canella-tree.

Canella alba. The pharmacopœial name of the laurel-leaved canella. See *Winteria aromatica.*

Canella cubana. See *Canella alba.*

Canellæ malabaricæ cortex. See *Laurus cassia.*

Canelli'fera malabarica. See *Laurus cassia.*

Caneon. (From καννη, because it was made of split cane.) A sort of tube or instrument, mentioned by Hippocrates, for conveying the fumes of antihysteric drugs into the womb.

Ca'nicæ. (From *canis*, a dog, so called by the ancients, because it was food for dogs.) Coarse meal. Hence *panis caniceus* means very coarse bread.

CANICI'DA. (From *canis*, a dog, and *cædo*, to kill; so called because dogs are destroyed by eating it.) Dog's bane. See *Aconitum.*

CANICI'DIUM. (From *canis*, a dog, and *cædo*, to kill.) The anatomical dissection of living dogs; for the purpose of illustrating the physiology of parts.

Canina lingua. See *Cynoglossum.*

Canina malus. The mandragora.

Canina rabies. See *Hydrophobia.*

CANINE. Whatever partakes of, or has any relation to, the nature of a dog.

Canine appetite. See *Bulimia.*

Canine madness. See *Hydrophobia.*

Canine teeth. *Dentes canini*; *Cynodontes*; *Cuspidati* of Mr. John Hunter; because they have the two sides of their edge sloped off to a point, and this point is very sharp or cuspidated; *columellares* of Varo and Pliny. The four eye-teeth are so called from their resemblance to those of the dog. See *Teeth.*

CANI'NUS. (From *canis*, a dog.) 1. A tooth is so called, because it resembles that of a dog. See *Teeth.*

2. The name of a muscle, because it is near the canine tooth. See *Levator anguli oris.*

3. A disease to which dogs are subject is called *rabies canina*. See *Hydrophobia.*

Caninus sentis. See *Rosa canina.*

Caniru'bus. (From *canis*, and *rubus*, a bramble.) See *Rosa canina.*

CA'NIS. 1. A dog. The white dung of this animal, called *album græcum*, was formerly in esteem, but now disused.

2. The frænum of the penis.

Canis interfector. Indian barley. See *Veratrum sabadilla.*

Canis ponticus. See *Castor*.

CANNA. (Hebrew.) 1. A reed or hollow cane.

2. The fibula, from its resemblance to a reed.

Canna fistula. See *Cassia fistula.*

Canna indica. See *Sagittaria alexipharmica.*

Canna major. The tibia.

Canna minor cruris. The fibula.

Cannabi'na. (From *canna*, a reed, named from its reed-like stalk.) So Tournefort named the *datisca*.

CA'NNABIS. (From *καννα*, a reed. Κανναβοι are foul springs, wherein hemp, &c. grow naturally. Or from *kanaba*, from *kanah*, to mow, Arabian.) Hemp. 1. The name of a genus of plants in the Linnæan system. Class, *Diœcia;* Order, *Pentandria.*

2. The pharmacopœial name of the hemp-plant. See *Cannabis sativa.*

Cannabis sativa. The systematic name of the hemp-plant. It has a rank smell of a narcotic kind. The effluvia from the fresh herb are said to affect the eyes and head, and that the water in which it has been long steeped is a sudden poison. Hemp-seeds, when fresh, afford a considerable quantity of oil. Decoctions and emulsions of them have been recommended against coughs, ardor urinæ, &c. Their use, in general, depends on their emollient and demulcent qualities. The leaves of an oriental hemp, called *bang* or *bangue*, and by the Egyptians *assis*, are said to be used in eastern countries, as a narcotic and aphrodisiac. See *Bangue.*

CA'NNULA. (Diminutive of *canna*, a reed.) The name of a surgical instrument. See *Canula.*

CA'NON. Κανων. A rule or canon, by which medicines are compounded.

Cano'nial. Κανονιαι. Hippócrates in his book De Aëre, &c. calls those persons thus, who have straight, and not prominent bellies. He would intimate that they are disposed, as it were, by a straight rule.

Cano'picon. (From *κανωπον*, the flower of the elder.) 1. A sort of spurge named from its resemblance.

2. A collyrium, of which the chief ingredient was elder flowers.

Canopi'te. The name of a collyrium mentioned by Celsus.

Cano'pum. Κανωπον. The flower or bark of the elder tree, in Paulus Ægineta.

Canta'brica. See *Convolvulus.*

Canta'brum. (From *kanta*, Hebrew.) In Cœlius Aurelianus it signifies bran.

Ca'ntacon. Garden saffron.

Ca'ntara. The plant which bears the St. Ignatius's bean. See *Ignaria amara.*

CANTERBURY. The name in history of a much celebrated town in Kent, in which there is a mineral water, *Cantuariensis aqua*, strongly impregnated with iron, sulphur, and carbonic acid gas; it is recommended in disorders of the stomach, in gouty complaints, jaundice, diseases of the skin, and chlorosis.

Ca'nthari figulini. Earthen cucurbits.

CA'NTHARIS. (*Cantharis*, pl. *cantharides:* from *κανθαρος*, a beetle, to which tribe it belongs.) *Musca Hispanica; Lytta vesicatoria;* The blistering fly; Spanish fly. These flies have a green shining gold body, and are common in Spain, Italy, France, and Germany. The largest come from Italy, but the Spanish cantharides are generally preferred. The importance of these flies, by their stimulant, corrosive, and epispastic qualities, in the practice of physic and surgery, is very considerable; indeed, so much so as to induce many to consider them as the most powerful medicine in the materia medica. When applied on the skin, in the form of a plaster, it soon raises a blister full of serous matter, and thus relieves inflammatory diseases, as phrenitis, pleuritis, hepatitis, phlegmon, bubo, myositis, arthritis, &c. The tincture of these flies is also of great utility in several cutaneous diseases, rheumatic affections, sciatic pains, &c. but ought to be used with much caution. See *Blister*, and *Tinctura cantharidis.* This insect is two-thirds of an inch in length, one-fourth in breadth, oblong, and of a gold shining colour, with soft elytera or wing sheaths, marked with three longitudinal raised stripes, and covering brown membraneous wings. An insect of a square form, with black feet, but possessed of no vesicating property, is sometimes mixed with the cantharides. They have a heavy disagreeable odour, and acrid taste.

If the inspissated watery decoction of these insects be treated with pure alkohol, a solution of a resinous matter is obtained, which being separated by gentle evaporation to dryness, and submitted for sometime to the action of sulphuric æther, forms a yellow solution. By spontaneous evaporation, crystalline plates are deposited, which may be freed from some adhering colouring matter by alkohol. Their appearance is like spermaceti. They are soluble in boiling alkohol, but precipitate as it cools. They do not dissolve in water. According to Robiquet, who first discovered them, these plates form the true blistering principle. They might be called *Vesicatoria.* Besides the above peculiar body, cantharides contain, according to Robiquet, a green bland oil, insoluble in water, soluble in alkohol; a black matter, soluble in water, insoluble in alkohol, without blistering properties; a yellow viscid matter, mild, soluble in water and alkohol; the crystalline plates; a fatty bland matter; phosphates of lime and magnesia; a little acetic acid, and much lithic or uric acid. The blistering fly taken into the stomach in doses of a few grains, acts as a poison, occasioning horrible satyriasis, delirium, convulsions, and death. Some frightful cases are related by Orfila, vol. i. part 2d. Oils, milk, syrups, frictions on the spine, with volatile liniment and laudanum, and draughts containing musk, opium, and camphorated emulsion, are the best antidotes.

Ca'nthum. Sugar-candy.

CA'NTHUS. (*Κανθος*, the tire or iron binding of a cart-wheel. Dr. Turton, in his glossary, supposes from its etymology, that it originally signified the circular extremity of the eyelid.) The angle or corner of the eye, where the upper and under eyelids meet. That next the nose is termed the internal or greater canthus; and the other the external or lesser canthus.

Cantion. Sugar.

CA'NULA. (Diminutive of *canna*, a reed.) *Cannula.* A small tube. The term is generally applied to a tube adapted to a sharp instrument, with which it is thrust into a cavity or tumour, containing a fluid; the perforation being made, the sharp instrument is withdrawn, and the canula left, in order that the fluid may pass through it.

Canusa. Crystal.

CAOUTCHOU'C. The substance so called is obtained from the vegetable kingdom, and exists also in the mineral.

1. The first known by the names Indian rubber, Elastic gum, Cayenne resin, Cautchuc, and Caoutchouc, is prepared principally from the juice of the *Siphonia elastica;—foliis ternatis ellipticis integerrimis subtus canis longe petiolatis* (Suppl. Plant.) and also from the *Jatropha elas-*

tica and *Unceola elastica.* The manner of obtaining this juice is by making incisions through the bark of the lower part of the trunk of the tree, from which the fluid resin issues in great abundance, appearing of a milky whiteness as it flows into the vessel placed to receive it, and into which it is conducted by means of a tube or leaf fixed in the incision, and supported with clay. On exposure to the air, this milky juice gradually inspissates into a soft, reddish, elastic, resin. It is formed by the Indians in South America into various figures, but is commonly brought to Europe in that of pear-shaped bottles, which are said to be formed by spreading the juice of the Siphonia over a proper mould of clay; as soon as one layer is dry, another is added, until the bottle be of the thickness desired. It is then exposed to a thick dense smoke, or to a fire, until it becomes so dry as not to stick to the fingers, when, by means of certain instruments of iron, or wood, it is ornamented on the outside with various figures. This being done, it remains only to pick out the mould, which is easily effected by softening it with water.

"The elasticity of this substance is its most remarkable property: when warmed, as by immersion in hot water, slips of it may be drawn out to seven or eight times their original length, and will return to their former dimensions nearly. Cold renders it stiff and rigid, but warmth restores its original elasticity. Exposed to the fire it softens, swells up, and burns with a bright flame. In Cayenne it is used to give light as a candle. Its solvents are æther, volatile oils, and petroleum. The æther, however, requires to be washed with water repeatedly, and in this state it dissolves it completely. Pelletier recommends to boil the caoutchouc in water for an hour; then to cut it into slender threads; to boil it again about an hour; and then to put it into rectified sulphuric æther in a vessel close stopped. In this way he says it will be totally dissolved in a few days, without heat, except the impurities, which will fall to the bottom if æther enough be employed. Berniard says, the nitrous æther dissolves it better than the sulphuric. If this solution be spread on any substance, the æther evaporates very quickly, and leaves a coating of caoutchouc unaltered in its properties. Naphtha, or petroleum, rectified into a colourless liquid, dissolves it, and likewise leaves it unchanged by evaporation. Oil of turpentine softens it, and forms a pasty mass, that may be spread as a varnish, but is very long in drying. A solution of caoutchouc in five times its weight of oil of turpentine, and this solution dissolved in eight times its weight of drying linseed oil by boiling, is said to form the varnish of air-balloons. Alkalies act upon it so as in time to destroy its elasticity. Sulphuric acid is decomposed by it; sulphurous acid being evolved, and the caoutchouc converted into charcoal. Nitric acid acts upon it with heat; nitrous gas being given out, and oxalic acid crystallizing from the residuum. On distillation it gives out ammonia, and carburetted hydrogen.

Caoutchouc may be formed into various articles without undergoing the process of solution. If it be cut into a uniform slip of a proper thickness, and wound spirally round a glass or metal rod, so that the edges shall be in close contact, and in this state be boiled for some time, the edges will adhere so as to form a tube. Pieces of it may be readily joined by touching the edges with the solution in æther; but this is not absolutely necessary, for, if they be merely softened by heat, and then pressed together, they will unite very firmly.

If linseed oil be rendered very drying by digesting it upon an oxide of lead, and afterward applied with a small brush on any surface, and dried by the sun or in the smoke, it will afford a pellicle of considerable firmness, transparent, burning like caoutchouc, and wonderfully elastic. A pound of this oil, spread upon a stone, and exposed to the air for six or seven months, acquired almost all the properties of caoutchouc: it was used to make catheters and bougies, to varnish balloons, and for other purposes.

Of the mineral caoutchouc there are several varieties: 1. Of a blackish-brown inclining to olive, soft, exceedingly compressible, unctuous, with a slightly aromatic smell. It burns with a bright flame, leaving a black oily residuum, which does not become dry. 2. Black, dry, and cracked on the surface, but, when cut into, of a yellowish-white. A fluid resembling pyrolignic acid exudes from it when recently cut. It is pellucid on the edges, and nearly of a hyacinthine red colour. 3. Similar to the preceding, but of a somewhat firmer texture, and ligneous appearance, from having acquired consistency in repeated layers. 4. Resembling the first variety, but of a darker colour, and adhering to grey calcareous spar, with some grains of galæna. 5. Of a liver-brown colour, having the aspect of the vegetable caoutchouc, but passing by gradual transition into a brittle bitumen, of vitreous lustre, and a yellowish colour. 6. Dull reddish-brown, of a spongy or cork-like texture, containing blackish-grey nuclei of impure caoutchouc. Many more varieties are enumerated.

One specimen of this caoutchouc has been found in a petrified marine shell enclosed in a rock, and another enclosed in a crystallised fluor spar.

The mineral caoutchouc resists the action of solvents still more than the vegetable. The rectified oil of petreolum affects it most, particularly when by partial burning it is resolved into a pitchy viscous substance. A hundred grains of a specimen analysed in the dry way by Klaproth, afforded carburetted hydrogen gas 38 cubic inches, carbonic acid gas 4, bituminous oil 73 grains, acidulous phlegm 1.5, charcoal 6.25, lime 2, silex 1.5, oxide of iron .75, sulphate of lime .5, alumina .25.

CAPAIBA. See *Copaifera officinalis.*

CAPAIVA. See *Copaifera officinalis.*

CAPELI'NA. (From *capeline*, French, a woman's hat, or bandage.) A double-headed roller put round the head.

CAPE'LLA. A cupel or test.

CAPER. See *Capparis.*

Caper-bush. See *Capparis.*

CA'PETUS. (Καπετος, *per aphæresin*, pro σκαπετος; from σκαπτω, to dig.) Hippocrates means by this word a foramen, which is impervious, and needs the use of a chirurgical instrument to make an opening; as the anus of some new-born infants.

CA'PHORA. (Arabian.) Camphire.

CA'PHURA BAROS INDORUM. A name for camphire.

CAPHURÆ OLEUM. An aromatic oil distilled from the root of the cinnamon-tree.

CAPILLACEUS. Capillary.

CAPILLARIS. See *Capillary.*

CAPILLARES PLANTÆ. Capillary, or hair-shaped plants.

CAPILLARIS VERMICULUS. See *Crinones* and *Dracunculus.*

CAPI'LLARY. (*Capillaris*; from *capillus*, a little hair: so called from the resemblance to hair or fine thread.) 1. Capillary vessels. The very small ramifications of the arteries, which terminate upon the external surface of the body, or on the surface of internal cavities, are called capillary.

2. Capillary attraction. See *Attraction.*

3. Applied to parts of plants, which are, or resemble, hairs: thus, a capillary root is one which consists of many very fine fibres, as that of *Festuca ovina*, and most grasses.

Capilla′tio. (From *capillus*, a hair.) A capillary fracture of the cranium.

CAPI′LLUS. (Quasi *capitis pilus*, the hair of the head.) The hair. Small, cylindrical, transparent, insensible, and elastic filaments, which arise from the skin, and are fastened in it by means of small roots. The human hair is composed of a spongy, cellular texture, containing a coloured liquid, and a proper covering. Hair is divided into two kinds; *long*, which arises on the scalp, cheek, chin, breasts of men, the anterior parts of the arms and legs, the arm-pits, groins, and pelvis: and *short*, which is softer than the long, and is present over the whole body, except only the palm of the hand and sole of the foot. The hair originates in the adipose membrane from an oblong membraneous bulb, which has vessels peculiar to it. The hair is distinguished by different names in certain parts; as, *capillus*, on the top of the head; *crinis*, on the back of the head; *circinnus*, on the temples; *cilium*, on the eyelids; *supercilium*, on the eyebrows; *vibrissa*, in the nostrils; *barba*, on the chin; *pappus*, on the middle of the chin; *mystax*, on the upper lip; *pilus*, on the body.

From numerous experiments Vauquelin infers, that black hair is formed of nine different substances, namely:—

1. An animal matter, which constitutes the greater part. 2. A white concrete oil, in small quantity. 3. Another oil of a greyish-green colour, more abundant than the former. 4. Iron, the state of which in the hair is uncertain. 5. A few particles of oxide of manganese. 6. Phosphate of lime. 7. Carbonate of lime, in very small quantity. 8. Silex, in a conspicuous quantity. 9. Lastly, a considerable quantity of sulphur.

The same experiments show, that red hair differs from black only in containing a red oil instead of a blackish-green oil; and that white hair differs from both these only in the oil being nearly colourless, and in containing phosphate of magnesia, which is not found in them.

Capillus veneris. See *Adianthum.*

Capillus veneris canadensis. See *Adianthum canadense.*

Capiple′nium. (From *caput*, the head, and *plenus*, full; a barbarous word: but Baglivi uses it to signify that continual heaviness or disorder in the head, which the Greeks call καρηβαρια.) A catarrh.

Capistra′tio. (From *capistrum*, a bridle: so called because the præpuce is restrained as it were with a bridle.) See *Phimosis.*

CAPI′STRUM. (From *caput*, the head.) 1. A bandage for the head is so called.

2. In Vogel's Nosology it is the same as *Trismus.*

CA′PITAL. *Capitalis.* 1. Belonging to the caput, or head.

2. The head or upper part of an alembic.

Capita′lia. (From *caput*, the head.) Medicines which relieve pains of the head.

CAPITATUS. (From *caput*, the head.) Headed. See *Capitulum.*

CAPITE′LLUM. The head or seed vessels, frequently applied to mosses, &c.

CAPITILU′VIUM. (From *caput*, the head, and *lavo*, to wash.) A lotion for the head.

Ca′pitis obliquus inferior et major. See *Obliquus inferior capitis.*

Capitis par tertium fallopii. See *Trachelo-mastoideus.*

Capitis posticus. See *Rectus capitis posticus major.*

Capitis rectus. See *Rectus capitis posticus minor.*

CAPI′TULUM. (Diminutive of *caput*, the head.) 1. A small head.

2. A protuberance of a bone, received into the concavity of another bone.

3. An Alembic.

In botany, the term for a species of inflorescence, called a head or tuft, formed of many flowers, in a globular form, upon a common peduncle.

From the insertion of the flowers, it is called,

1. *Pedunculated;* as in *Astragalus syriacus*, and *Eryngium maritimum.*
2. *Sessile;* as in *Trifolium tomentosum.*
3. *Terminal;* as in *Monarda fistulosa.*
4. *Axillary;* as in *Gomphrena sessilis.*

From the figure, it is said to be,

1. *Globose;* as in *Gomphrena globosa.*
2. *Subrotund;* as in *Trifolium pratense.*
3. *Conic;* as in *Trifolium montanum.*
4. *Dimidiate*, flat on one side, round on the other; as in *Trifolium lupinaster.*

From its covering,

1. *Naked;* as in *Illecebrum polygonoides.*
2. *Foliose;* as in *Plantago indico.*

A capitulum that is very small, and is mostly in the axilla, is called *Glomerûlus.*

CAPI′VI. See *Copaifera officinalis.*

CAPNELÆ′UM. (From καπνος, smoke, and ελαιον, oil; so named from its smoky exhalations when exposed to heat.) In Galen's works it means a resin.

Ca′pnias. (From καπνος, a smoke.) 1. A jasper of a smoky colour.

2. A vine which bears white and part black grapes.

Capni′ston. (From καπνος, smoke.) A preparation of spice and oil, made by kindling the spices, and fumigating the oil.

Capni′tis. (From καπνος, smoke; so called from its smoky colour.) Tutty.

CAPNOI′DES. (From καπνος, fumitory, and ειδος, likeness.) Resembling fumitory.

CA′PNOS. (Καπνος, smoke; so called, says Blanchard, because its juice, if applied to the eyes, produces the same effect and sensations as smoke.) *Capnus.* The herb fumitory. See *Fumaria.*

CAPNUS. See *Capnos.*

Ca′ppa. (*à capite*, from the head: so called from its supposed resemblance.) The herb monkshood. See *Aconitum.*

CA′PPARIS. (From *cabar*, Arab. or ϖαρα το καππανειν αραν, from its curing madness and melancholy.) The caper plant.

1. The name of a genus of plants in the Linnæan system. Class, *Polyandria;* Order, *Monogynia.*

2. The pharmacopœial name of the caper plant. See *Capparis spinosa.*

Capparis spinosa. The systematic name of the caper plant. *Capparis:—penduncculis solitariis unifloris, stipulis spinosis, foliis unnuis, capsulis ovalibus* of Linnæus. The buds, or unexpanded flowers of this plant, are in common use as a pickle, which is said to possess antiscorbutic virtues. The bark of the root was formerly in high esteem as a deobstruent.

CAPREOLA′RIS. (From *capreolus*, a tendril.) *Capreolatus.* Resembling in its contortions, or other appearance, the tendrils of a vine; applied to the spermatic vessels.

CAPREOLA′TUS. See *Capreolaris.*

CAPRE′OLUS. (Dim. of *caprea*, a tendril. Dr. Turton suggests its derivation from *caper*, a goat, the horn of which its contortions somewhat resemble.) 1. The helix or circle of the ear, from its tendril-like contortion.

2. A Tendril. See *Cirrus.*

Caprico′rnus. Lead.

CAPRIFICATION. (*Caprificatio*; from *caprificus*, a wild fig.) The very singular husbandry, or management of fig-trees.

CAPRIFI′CUS. (From *caper*, a goat, and *ficus*, a fig; because they are a chief food of goats.) The wild fig-tree. See *Ficus.*

Capri′zans. Galen and others used this word to express an inequality in the pulse, when it leaps, and, as it were, dances in uncertain strokes and periods.

Capse′lla. (Diminutive of *capsa*, a chest, from its resemblance.) A name in Marcellus Empiricus for viper's bugloss; the *Echium Italicum*, of Linnæus.

CA′PSICUM. (From *καπτω*, to bite; on account of its effect on the mouth.)

1. The name of a genus of plants in the Linnæan system. Class, *Pentandria*; Order *Monogynia.*

2. The pharmacopœial name of the capsicum. See *Capsicum annuum.*

Capsicum annuum. The systematic name of the plant from which we obtain Cayenne pepper. Guinea pepper. *Piper indicum; Lada chilli; Capo molago; Solanum urens; Siliquastrum Plinii; Piper Brazilianum; Piper Guineense; Piper Calecuticum; Piper Hispanicum; Piper Lusitanicum.* Cayenne pepper. This species of pepper is obtained from the *Capsicum; caule herbaceo, pedunculis solitariis* of Linnæus. What is generally used under the name of Cayenne pepper, however, is an indiscriminate mixture of the powder of the dried pods of many species of capsicum, but especially of the capsicum minimum, or bird pepper, which is the hottest of all. These peppers have been chiefly used as condiments. They prevent flatulence from vegetable food, and give warmth to the stomach, possessing all the virtues of the oriental spices, without producing those complaints of the head which the latter are apt to occasion. An abuse of them, however, gives rise to visceral obstructions, especially of the liver. In the practice of medicine, there can be little doubt that they furnish us with one of the purest and strongest stimulants which can be introduced into the stomach, and may be very useful in some paralytic and gouty cases. Dr. Adair, who first introduced them into practice, found them useful in the cachexia Africana, which he considers as a most frequent and fatal predisposition to disease among the slaves. Dr. Wright says, that in dropsical and other complaints where chalybeates are indicated, a minute portion of powdered capsicum forms an excellent addition, and recommends its use in lethargic affections. This pepper has also been successfully employed in a species of cynanche maligna, which proved very fatal in the West Indies, resisting the use of Peruvian bark, wine, and other remedies commonly employed. In tropical fevers, coma and delirium are common attendants; and in such cases, cataplasms of capsicum have a speedy and happy effect. They redden the parts, but seldom blister unless when kept on too long. In ophthalmia from relaxation, the diluted juice of capsicum is found to be a valuable remedy. Dr. Adair gave six or eight grains for a dose, made into pills; or else he prepared a tincture by digesting half an ounce of the pepper in a pound of alkohol, the dose of which was one or two drachms, diluted with a sufficient quantity of water. A *tinctura capsici* is now for the first time introduced into the London pharmacopœia.

CA′PSULA. (Diminutive of *capsa*, a chest or case.) A capsule. 1. A membraneous production enclosing a part of the body like a bag; as the capsular ligaments, the capsule of the crystalline lens, &c.

2. In botany, a dry, woody, coriaceous or membraneous pericarpium, or seed-vessel, generally splitting into several valves.

The parts of a capsule, are,

1. The *valves*, or external shell, into which the capsule splits.

2. The *sutures*, or the external surface in which the valves are joined.

3. The *dissepimenta*, or partitions by which the capsule is divided into several cells.

4. The *loculamenta*, or cells, the spaces between the partitions and valves.

5. The *columella*, or central column, or filament, which unites the partitions, and to which the seeds are usually attached.

From the number of the valves, a capsule is said to be,

1. *Bivalved*; as in *Magnolia*, and *Capraria.*

2. *Three-valved*; as in *Canna indica.*

3. *Four-valved*; as in *Datura stramonium* and *Œnothera biennis.*

4. *Five-valved*; as in *Illecebrum*, and *Coris.*

5. *Manyvalved*; as in *Hura crepitans.*

6. *Operculate*, or *circumcised*, the operculum splitting horizontally; as in *Hyosciamus niger*, and *Lecythis ollaria.*

From the number of *cells*,

1. *Unilocular*, when there is no partition; as in *Parnassia palustris*, and *Agrostema.*

2. *Bilocular*, two celled; as *Hyosciamus niger*, and *Datura stramonium.*

3. *Trilocular*, three-celled; as in *Æsculus hypocastanum*, and *Iris Germanica.*

4. *Quinquelocular*, five-celled; as in *Hibiscus syriacus*, and *Azalea procumbens.*

5. *Novemlocular*, nine-celled; as in *Punica granatum.*

6. *Submultilocular*, when there are many cells, and the partitions do not reach the middle of the capsule; as in *Papaver somniferum.*

From the appearance of the external surface, a capsule is called,

1. *Glabrous*; as in *Papaver somniferum.*

2. *Aculeate*; as in *Datura stramonium.*

3. *Muricate*; as in *Canna indica.*

From the number of tubercles on the external surface.

1. *Capsula dicocca*, or *didyma*; as in *Spigelia.*

2. *C. tricocca*; as in *Euphorbia lathyrus*, and *Gneorum tricoccum.*

3. *C. tetracocca*; as in *Paururus cernuus*, and *Evonymus europeus.*

From the number of contiguous capsules,

1. *C. simplex*, if solitary.

2. *C. duplex*, two aggregated; as in *Pæonia officinalis.*

3. *C. triplex*; as in *Veratrum album.*

4. *C. quintuplex*; as in *Aquilegia vulgaris*, and *Nigella.*

5. *C. multiplex*; as in *Sempervivum tectorum.*

From the substance, a capsule is called,

1. *Membranaceous*; as in *Datura stramonium.*

2. *Corticated*, the external fungous membrane receding from the capsule; as in *Ricinus communis.*

3. *Woody*, very hard, yet splitting; as in *Hura crepitans.*

4. *Baccated*, when the seed is surrounded by a pulp; as *Evonymus europeus*, and *Samyda.*

5. *Spurious*, if the calyx, capsule-like, surrounding the seed, splits; as in *Fagus sylvatica.*

The number of seeds contained in the capsule, gives rise to the following distinctions.

1. *Capsula monosperma*, one-seeded; as in *Gomphrenia*, *Herniaria*, and *Salsola.*

2. *C. disperma*, two-seeded; as in *Hebenstratia*, and *Buffonia.*

3. *C. Trisperna*, three-seeded; as in *Glaux* and *Hudsonia.*

4. *C. polysperma*, many-seeded; as in *Papaver somniferum.*

Capsula atrabilaris. See *Renal Glands.*

Capsula renalis. See *Renal Glands.*

CA'PSULAR. (*Capsularis; from capsa*, a bag.) Surrounding a part, like a bag: applied to a ligament which surrounds every moveable articulation, and contains the synovia like a bag.

CA'PSULE. See *Capsula.*

Capsule of glisson. *Capsula Glissonii. Vagina portæ, Vagina Glissonii.* A strong tunic, formed of cellular texture, which accompanies the vena portæ, and its most minute ramifications, throughout the whole liver.

Ca'pulum. (From καμπτω, to bend.) A contortion of the eye-lids, or other parts.

Ca'pur. (Arabian.) Camphire.

CA'PUT. (*Caput, itis.* neut.; from *capio*, to take; because from it, according to Varro, the senses take their origin.) 1. The head, cranium, or skull. It is situated above or upon the trunk, and united to the cervical vertebræ. It is distinguished into skull and face. On the skull are observed *vertex*, or crown; *sinciput*, or fore parts; *occiput*, or hinder part; and the *temples.* The parts distinguished on the face are well known; as the forehead, nose, eyes, &c. The arteries of the head are branches of the carotids; and the veins empty themselves into the jugulars. See *Skull* and *Face.*

2. The upper extremity of a bone; as the head of the humerus or femur.

3. The origin of a muscle; as the long head of the biceps.

4. A protuberance like the head of any thing; as caput gallinaginis.

5. The beginning of a part; as caput cœci.

6. The remains of any thing after its destruction by fire, or other means; hence caput mortuum.

Caput gallinaginis. *Verumontanum.* A cutaneous eminence in the urethra of men, before the neck of the bladder, somewhat like the head of a woodcock in miniature, around which the seminal ducts, and the ducts of the prostate gland, open.

Caput mortuum. A fanciful term, much used by the old chemists, but now entirely rejected. It denoted the fixed residue of operations. As the earlier chemists did not examine these, they did not find any inconvenience in one general term to denote them: but the most slender acquaintance with modern chemistry must show, that it is utterly impracticable to denote, by one general term, all the various matters that remain fixed in certain degrees of heat. The term is obsolete.

Caput obstipum. The wry neck. Mostly a spasmodic complaint.

Caput purgia. (A barbarous word, from *caput*, the head, and *purgo*, to purge.) Medicines which, by causing a defluxion from the nose, purge, as it were, the head, as some errhines do.

Capyri'dion. (From καπυρος, burnt.) *Capyrion.* A medicated cake, much baked.

Capy'rion. See *Capyridion.*

Ca'rabe. (Persian.) Amber.

Carabe funerum. A bitumen.

CA'RABUS. A genus of insects of the beetle kind. Two species, the *chrysocephalus* and *ferrugineus*, have been recommended for the toothache. They must be pressed between the fingers, and then rubbed on the gum and tooth affected.

Caraco'smos. A name of the sour mare's milk, so much admired by the Tartars.

Caragua'ta. The aloe of Brazil.

CARA'NNA. (Spanish.) *Caragna. Carannæ gummi. Bresilis.* A concrete resinous juice, that exudes from a large tree, of which we have no particular account. It is brought from New Spain and America, in little masses, rolled up in leaves of flags; externally and internally it is of a brownish colour, variegated with irregular white streaks. When fresh, it is soft and tenacious; but becomes dry and friable by keeping. Pure caranna has an agreeable aromatic smell, especially when heated, and a bitterish slightly pungent taste. It was formerly employed as an ingredient in vulnerary balsams, strengthening, discutient, and suppurating plasters; but its scarcity has caused it to be forgotten.

CARAWAY. See *Carum.*

Ca'rbasus. Καρβασος. Scribonius Largus uses this word for lint.

CA'RBO. (*Charbah*; Hebrew, burnt or dried.) Coal.

1. In medicine and chemistry, it is commonly understood to mean charcoal, and receives its name from its mode of preparation, which is by burning pieces of light wood into a dry black coal.

2. A carbuncle. See *Anthrax.*

Carbo ligni. Charcoal. As an external application, powdered charcoal has been recommended in the cure of gangrene, from external causes, and all descriptions of fœtid ulcers. Meat which has acquired a mawkish or even putrid smell, is found to be rendered perfectly sweet, by rubbing it with powdered charcoal. It is also used as tooth-powder.

CA'RBON. (From *carbo*, coal.) Chemists apply this term to the diamond and what is commonly called charcoal. The diamond is the purest form of it.

1. "When vegetable matter, particularly the more solid, as wood, is exposed to heat in close vessels, the volatile parts fly off, and leave behind a black porous substance, which is charcoal. If this be suffered to undergo combustion in contact with oxygen, or with atmospheric air, much the greater part of it will combine with the oxygen, and escape in the form of gas; leaving about a two-hundredth part, which consists chiefly of different saline and metallic substances. This pure inflammable part of the charcoal is what is commonly called *carbon*; and if the gas be received into proper vessels, the carbon will be found to have been converted by the oxygen into an acid, called the carbonic. See *Carbonic acid.*

From the circumstance, that inflammable substances refract light in a ratio greater than that of their densities, Newton inferred, that the diamond was inflammable. The quantity of the inflammable part of charcoal, requisite to form a hundred parts of carbonic acid, was calculated by Lavoisier to be twenty-eight parts. From a careful experiment of Mr. Tennant, 27.6 parts of diamond, and 72.4 of oxygen, formed 100 of carbonic acid; and hence he inferred the identity of diamond and the inflammable part of charcoal.

Well-burned charcoal is a conductor of electricity, though wood simply deprived of its moisture by baking is a nonconductor; but it is a very bad conductor of caloric, a property of considerable use on many occasions, as in lining crucibles.

It is insoluble in water, and hence the utility of charring the surface of wood exposed to that liquid, in order to preserve it, a circumstance not unknown to the ancients. This preparation of timber has been proposed as an effectual preventive of what is commonly called the dry rot. It has an attraction, however, for a certain portion of water, which it retains very forcibly. Heated red-hot, or nearly so, it decomposes water; forming with its oxygen carbonic acid, or carbonic oxyde, according to the quantity present; and with the hydrogen a gaseous carburet, called carburetted hydrogen, or heavy inflammable air.

Charcoal is infusible by any heat. If exposed to a very high temperature in close vessels, it loses little or nothing of its weight, but shrinks, becomes more compact, and acquires a deeper black colour.

Recently prepared charcoal has a remarkable property of absorbing different gases, and condensing them in its pores, without any alteration of their properties or its own.

Very light charcoal, such as that of cork, absorbs scarcely any air; while the pit-coal of Rastiberg, sp. gr. 1.326, absorbs ten times and a half its volume. The absorption was always completed in 24 hours. This curious faculty, which is common to all porous bodies, resembles the action of capillary tubes on liquids. When a piece of charcoal, charged with one gas, is transferred into another, it absorbs some of it, and parts with a portion of that first condensed. In the experiments of Messrs. Allen and Pepys, charcoal was found to imbibe from the atmosphere in a day about one-eighth of its weight of water. For a general view of absorption, see *Gas*.

When oxygen is condensed by charcoal, carbonic acid is observed to form at the end of several months. But the most remarkable property displayed by charcoals impregnated with gas, is that with sulphuretted hydrogen, when exposed to the air or oxygen gas. The sulphuretted hydrogen is speedily destroyed, and water and sulphur result, with the disengagement of considerable heat. Hydrogen alone has no such effects. When charcoal was exposed by Sir H. Davy to intense ignition *in vacuo*, and in condensed azot, by means of Mr. Children's magnificent voltaic battery, it slowly volatilized, and gave out a little hydrogen. The remaining part was always much harder than before; and in one case so hard as to scratch glass, while its lustre was increased. This fine experiment may be regarded as a near approach to the production of diamond.

Charcoal has a powerful affinity for oxygen; whence its use in disoxygenating metallic oxides, and restoring their base to its original metallic state, or reviving the metal. Thus too it decomposes several of the acids, as the phosphoric and sulphuric, from which it abstracts their oxygen, and leaves the phosphorus and sulphur free.

Carbon is capable of combining with sulphur, and with hydrogen. With iron it forms steel; and it unites with copper into a carburet, as observed by Dr. Priestley.

A singular and important property of charcoal is that of destroying the smell, colour, and taste of various substances: for the first accurate experiments on which we are chiefly indebted to Mr. Lowitz, of Petersburgh, though it had been long before recommended to correct the fœtor of foul ulcers, and as an antiseptic. On this account it is certainly the best dentifrice. Water that has become putrid by long keeping in wooden casks, is rendered sweet by filtering through charcoal powder, or by agitation with it; particularly if a few drops of sulphuric acid be added. Common vinegar boiled with charcoal powder becomes perfectly limpid. Saline solutions, that are tinged yellow or brown, are rendered colourless in the same way, so as to afford perfectly white crystals. The impure carbonate of ammonia obtained from bones, is deprived both of its colour and fœtid smell by sublimation with an equal weight of charcoal powder. Malt spirit is freed from its disagreeable flavour by distillation from charcoal; but if too much be used, part of the spirit is decomposed. Simple maceration, for eight or ten days, in the proportion of about 1-150th of the weight of the spirit, improves the flavour much. It is necessary that the charcoal be well burned, brought to a red heat before it is used, and used as soon as may be, or at least be carefully excluded from the air. The proper proportion too should be ascertained by experiment on a small scale. The charcoal may be used repeatedly, by exposing it for some time to a red heat before it is again employed.

Charcoal is used on particular occasions as fuel, on account of its giving a strong and steady heat without smoke. It is employed to convert iron into steel by cementation. It enters into the composition of gunpowder. In its finer states, as in ivory black, lamp black, &c. it forms the basis of black paints, Indian ink, and printers' ink.

The purest carbon for chemical purposes is obtained by strongly igniting lamp black in a covered crucible. This yields, like the diamond, unmixed carbonic acid by combustion in oxygen.

Carbon unites with all the common simple combustibles, and with azot, forming a series of most important compounds. With sulphur it forms a curious limpid liquid, called carburet of sulphur, or sulphuret of carbon. With phosphorus it forms a species of compound, whose properties are imperfectly ascertained. It unites with hydrogen in two definite proportions, constituting subcarburetted and carburetted hydrogen gases. With azot it forms prussic gas, the cyanogen of Gay Lussac. Steel and plumbago are two different compounds of carbon with iron. In black chalk we find this combustible intimately associated with silica and alumina. The primitive combining proportion, or prime equivalent of carbon, is 0.75 on the oxygen scale.

2. *Carbon mineral.* This is of a grey blackish colour. It is charcoal with various proportions of earth and iron, without bitumen. It has a silky lustre, and the fibrous texture of wood. It is found in small quantities, stratified with brown coal, slate coal, and pitch coal.

CARBON, GASEOUS OXIDE OF. Gaseous oxide of carbon was first described by Dr. Priestley, who mistook it for a hydrocarbonate. With the true nature of it, we have been only lately acquainted. It was first proved to be a peculiar gas, by Mr. Cruikshank, of Woolwich, who made it known to us as such, in April, 1801, through the medium of Nicholson's Journal for that month. Several additional properties of this gas were soon afterwards noticed by Desormes, Clement, and others. Gaseous oxide of carbon forms an intermediate substance between the pure hydrocarbonates and carbonic acid gas; but not being possessed of acid properties, Mr. Cruikshank called it, conformably to the rules of the chemical nomenclature, *gaseous oxide of carbon*, for it consists of oxygen and carbon rendered gaseous by caloric. See *Carbonic oxide*.

Carbonaceous acid. See *Carbonic acid.*

CARBO'NAS. (*Carbonas, atis.* m.; from carbonic acid being one of its constituents.) A carbonate. A salt, formed by the union of carbonic acid with a salifiable basis. The carbonates employed in medicine are:

1. The potassæ carbonas.
2. The sodæ carbonas.
3. The creta præparata, and the testæ præparatæ, which are varieties of carbonate of lime.

When the base is imperfectly neutralised by the carbonic acid, the salt is termed a subcarbonate; of which kind are employed medicinally:

1. The potassæ subcarbonas.
2. The sodæ subcarbonas, and the sodæ subcarbonas exsiccata.
3. The ammoniæ subcarbonas, and the liquor ammoniæ subcarbonatis.
4. The plumbi subcarbonas.
5. The ferri subcarbonas.
6. The magnesiæ subcarbonas.

CARBONAS AMMONIÆ. See *Ammoniæ subcarbonas.*

CARBONAS CALCIS. Carbonate of lime. Several varieties of this are used in medicine: the purest and best are the creta præparata, testæ preparatæ, chelæ cancrorum, testæ ovorum, and oculi cancrorum.

CARBONAS FERRI. See *Ferri subcarbonas.*

CARBONAS MAGNESIÆ. See *Magnesiæ subcarbonas.*

CARBONAS PLUMBI. See *Plumbi subcarbonas.*

CARBONAS POTASSÆ. See *Potassæ carbonas.*

CARBONAS SODÆ. See *Sodæ carbonas.*

CARBONATE. See *Carbonas.*

Carbonate of barytes. See *Heavy spar.*

Carbonated-hydrogen gas. See *Carburetted hydrogen gas.*

CA'RBONIC ACID. *Acidum carbonicum.* Fixed air; Carbonaceous acid; Calcareous acid; Aërial acid. "This acid, being a compound of carbon and oxygen, may be formed by burning charcoal; but as it exists in great abundance ready formed, it is not necessary to have recourse to this expedient. All that is necessary is to pour sulphuric acid, diluted with five or six times its weight of water, on common chalk, which is a compound of carbonic acid and lime. An effervescence ensues; carbonic acid is evolved in the state of gas, and may be received in the usual manner.

Carbonic acid abounds in great quantities in nature, and appears to be produced in a variety of circumstances. It composes $\frac{44}{100}$ of the weight of limestone, marble, calcareous spar, and other natural specimens of calcareous earth, from which it may be extricated either by the simple application of heat, or by the superior affinity of some other acid; most acids having a stronger action on bodies than this. This last process does not require heat, because fixed air is strongly disposed to assume the elastic state. Water, under the common pressure of the atmosphere, and at a low temperature, absorbs somewhat more than its bulk of fixed air, and then constitutes a weak acid. If the pressure be greater, the absorption is augmented. It is to be observed, likewise, that more gas than water will absorb should be present. Heated water absorbs less; and if water impregnated with this acid be exposed on a brisk fire, the rapid escape of the aërial bubbles affords an appearance as if the water were at the point of boiling, when the heat is not greater than the hand can bear. Congelation separates it readily and completely from water; but no degree of cold or pressure has yet exhibited this acid in a dense or concentrated state of fluidity.

Carbonic acid gas is much denser than common air, and for this reason occupies the lower parts of such mines or caverns as contain materials which afford it by decomposition. The miners call it choke-damp. The Grotto del Cano, in the kingdom of Naples, has been famous for ages on account of the effects of a stratum of fixed air which covers its bottom. It is a cave or hole in the side of a mountain, near the lake Agnano, measuring not more than eighteen feet from its entrance to the inner extremity; where if a dog or other animal that holds down its head be thrust, it is immediately killed by inhaling this noxious fluid.

Carbonic acid gas is emitted in large quantities by bodies in the state of the vinous fermentation, and on account of its great weight, it occupies the apparently empty space or upper part of the vessels in which the fermenting process is going on. A variety of striking experiments may be made in this stratum of elastic fluid. Lighted paper, or a candle dipped into it is immediately extinguished; and the smoke remaining in the carbonic acid gas renders its surface visible, which may be thrown into waves by agitation like water. If a dish of water be immersed in this gas, and briskly agitated, it soon becomes impregnated, and obtains the pungent taste of Pyrmont water. In consequence of the weight of the carbonic acid gas, it may be lifted out in a pitcher, or bottle, which, if well corked, may be used to convey it to great distances, or it may be drawn out of a vessel by a cock like a liquid. The effects produced by pouring this invisible fluid from one vessel to another, have a very singular appearance: if a candle or small animal be placed in a deep vessel, the former becomes extinct, and the latter expires in a few seconds, after the carbonic acid gas is poured upon them, though the eye is incapable of distinguishing any thing that is poured. If, however, it be poured into a vessel full of air, in the sunshine, its density being so much greater than that of the air, renders it slightly visible by the undulations and streaks it forms in this fluid, as it descends through it.

Carbonic acid reddens infusion of litmus; but the redness vanishes by exposure to the air, as the acid flies off. It has a peculiar sharp taste, which may be perceived over vats in which wine or beer is fermenting, as also in sparkling Champaign, and the brisker kinds of cider. Light passing through it is refracted by it, but does not effect any sensible alteration in it, though it appears, from experiment, that it favours the separation of its principles by other substances. It will not unite with an overdose of oxygen, of which it contains 72 parts in 100, the other 28 being pure carbon. It not only destroys life, but the heart and muscle of animals killed by it lose all their irritability, so as to be insensible to the stimulus of galvanism.

Carbonic acid is dilated by heat, but not otherwise altered by it. It is not acted upon by oxygen, or any of the simple combustibles. Charcoal absorbs it, but gives it out again unchanged, at ordinary temperatures; but when this gaseous acid is made to traverse charcoal ignited in a tube, it is converted into carbonic oxide. Phosphorus is insoluble in carbonic acid gas; but, as already observed, is capable of decomposing it by compound affinity, when assisted by sufficient heat: and Priestley and Cruikshank have shown that iron, zinc, and several other metals, are capable of producing the same effect. If carbonic acid be mixed with sulphuretted, phosphuretted, or carburetted gas, it renders them less combustible, or destroys their combustibility entirely, but produces no other sensible change. Such mixtures occur in various analyses, and particularly in the products of the decomposition of vegetable and animal substances. The inflammable air of marshes is frequently carburetted hydrogen intimately mixed with carbonic acid gas, and the sulphuretted hydrogen gas obtained from mineral waters is very often mixed with it.

Carbonic acid appears from various experiments of Ingenhousz to be of considerable utility in promoting vegetation. It is probably decomposed by the organs of plants, its base furnishing part at least of the carbon that is so abundant in the vegetable kingdom, and its oxygen contributing to replenish the atmosphere with that necessary support of life, which is continually diminished by the respiration of animals and other causes.

The most exact experiments on the neutral carbonates concur to prove, that the prime equivalent of carbonic acid is 2.75; and that it consists of one prime of carbon $=0.75 + 2.0$ oxygen.

Water absorbs about its volume of this acid gas, and thereby acquires a specific gravity of 1.0015. On freezing it, the gas is as completely expelled as by boiling. By artificial pressure with forcing pumps, water may be made to absorb two or three times its bulk of carbonic acid. When there is also added a little potassa or soda, it becomes the *aërated* or *carbonated alkaline water*, a pleasant beverage, and a not inactive remedy in several complaints, particularly dyspepsia, hiccup, and disorders of the kidneys. Alkohol condenses twice its volume of carbonic acid. The most beautiful analytical experiment with carbonic acid, is the combustion of potassium in it, the formation of potassa, and the deposition of charcoal.

In point of affinity for the earths and alkalies, carbonic acid stands apparently low in the scale. Before its true nature was known, its compounds with them were not considered as salts, but as the earths and alkalies themselves, only distinguished by the names of *mild*, or *effervescent*, from their qualities of effervescing with acids, and wanting causticity.

The *carbonates* are characterised by effervescing with almost all the acids, even the acetic, when they evolve their gaseous acid, which, passed into lime water by a tube, deprives it of its taste, and converts it into chalk and pure water.

The carbonate of barytes, found native in Cumberland, by Dr. Withering. From this circumstance it has been termed Witherite. It has been likewise called *aërated heavy spar*, *aërated baroselenite*, *aërated heavy earth* or *barytes*, *barolite*, &c.

Carbonate of strontian, found native in Scotland, at Strontian in Argyllshire, and at Leadhills.

Carbonate of lime exists in great abundance in nature, variously mixed with other bodies, under the names of *marble*, *chalk*, *limestone*, *stalactites*, &c. in which it is of more important and extensive use than any other of the salts, except perhaps the muriate of soda.

The carbonate, or rather *sub-carbonate* of *potassa*, was long known by the name of *vegetable alkali*. It was also called *fixed nitre*, *salt of tartar*, *salt of wormwood*, &c. according to the different modes in which it was procured; and was supposed to retain something of the virtues of the substance from which it was extracted. This error has been sometime exploded, but the knowledge of its true nature is of more recent date.

As water at the usual temperature of the air dissolves rather more than its weight of this salt, we have thus a ready mode of detecting its adulterations in general; and as it is often of consequence to know how much alkali a particular specimen contains, this may be ascertained by the quantity of sulphuric acid it will saturate. This salt is deliquescent. It consists of 6 potassa $+ 2.75$ carbonic acid $= 8.75$.

The bi-carbonate of potassa crystallises in square prisms, the apices of which are quadrangular pyramids. It has a urinous but not caustic taste; changes the syrup of violets green: boiling water dissolves five-sixths of its weight, and cold water one-fourth; alkohol, even when hot, will not dissolve more than 1-1200th. Its specific gravity is 2.012. When it is very pure and well crystallised it effloresces on exposure to a dry atmosphere, though it was formerly considered as deliquescent. It was thought that the common salt of tartar of the shops was a compound of this carbonate and pure potassa; the latter of which, being very deliquescent, attracts the moisture of the air till the whole is dissolved. From its smooth feel, and the manner in which it was prepared, the old chemists called this solution *oil of tartar per deliquium.*

The bi-carbonate of potassa melts with a gentle heat, loses its water of crystallisation, amounting to $\frac{9}{100}$, and gives out a portion of its carbonic acid; though no degree of heat will expel the whole of the acid. Thus, as the carbonic of potassa is always prepared by incineration of vegetable substances, and lixiviation, it must be in the intermediate state; or that of a carbonate with excess of alkali: and to obtain the true carbonate we must saturate this salt with carbonic acid, which is best done by passing the acid in the state of gas through a solution of the salt in twice its weight of water; or, if we want the potassa pure, we must have recourse to lime, to separate that portion of acid which fire will not expel.

The bi-carbonate, usually called *supercarbonate* by the apothecaries, consists of 2 primes of carbonic acid $= 5.500$, one of potassa $= 6$, and 1 of water $= 1.125$, in all 12.625.

The carbonate of soda has likewise been long known, and distinguished from the preceding by the name of *mineral alkali*. In commerce it is usually called *barilla*, or *soda*; in which state, however, it always contains a mixture of earthy bodies, and usually common salt. It may be purified by dissolving it in a small portion of water, filtering the solution, evaporating at a low heat, and skimming off the crystals of muriate of soda as they form on its surface. When these cease to form, the solution may be suffered to cool, and the carbonate of soda will crystallise.

It is found abundantly in nature. In Egypt, where it is collected from the surface of the earth, particularly after the desiccation of temporary lakes, it has been known from time immemorial by the name of *nitrum*, *natron*, or *natrum*. A great deal is prepared in Spain by incinerating the maritime plant salsola; and it is manufactured in this country, as well as in France, from different species of sea-weeds. It is likewise found in mineral water, and also in some animal fluids.

It crystallises in irregular or rhomboidal decaëdrons formed by two quadrangular pyramids, truncated very near their bases. Frequently it exhibits only rhomboidal laminæ. Its specific gravity is 1.3591. Its taste is urinous, and slightly acrid, without being caustic. It changes blue vegetable colours to a green. It is soluble in less than its weight of boiling water and twice its weight of cold. It is one of the most efflorescent salts known, falling completely to powder in no long time. On the application of heat it is soon rendered fluid from the great quantity of its water of crystallisation; but is dried by a continuance of the heat, and then melts. It is somewhat more fusible than the carbonate of potassa, promotes the fusion of earths in a greater degree, and forms a glass of better quality. Like that, it is very tenacious of a certain portion of its carbonic acid. It consists in its dry state of 4 soda, + 2.75 acid, = 6.75.

But the crystals contain 10 prime proportions of water. They are composed of 22 soda, + 15.3 carbonic acid, + 62.7 water in 100 parts, or of 1 prime of soda = 4.1 of carbonic acid = 2.75, and 10 of water = 11.25, in whole 18.

The *bi-carbonate of soda* may be prepared by saturating the solution of the preceding salt with carbonic acid gas, and then evaporating with a very gentle heat to dryness, when a white irregular saline mass is obtained. The salt is not crystallisable. Its constituents are 4 soda, + 5.50 carb. acid, + 1.125 water = 10.625; or in 100 parts 37.4 soda, + 52 acid, + 10.6 water.

The carbonate of magnesia, in a state of imperfect saturation with the acid, has been used in medicine for some time under the simple name of magnesia. It is prepared by precipitation from the sulphate of magnesia by means of carbonate of potassa. Equal parts of sulphate of magnesia and carbonate of potassa, each dissolved in its own weight of boiling water, are filtered and mixed together hot; the sulphate of potassa is separated by copious washing with water; and the carbonate of magnesia is then left to drain, and afterwards spread thin on paper, and carried to the drying stove. When once dried it will be in friable white cakes, or a fine powder.

To obtain carbonate of magnesia saturated with acid, a solution of sulphate of magnesia may be mixed cold with a solution of carbonate of potassa; and at the expiration of a few hours, as the superfluous carbonic acid that held it in solution flies off, the carbonate of magnesia will crystallise in very regular transparent prisms of six equal sides. It may be equally obtained by dissolving magnesia in water impregnated with carbonic acid, and exposing the solution to the open air.

These crystals soon lose their transparency, and become covered with a white powder. Exposed to the fire in a crucible, they decrepitate slightly, lose their water and acid, fall to powder, and are reduced to one-fourth of the original weight. When the common carbonate is calcined in the great, it appears as if boiling, from the extrication of carbonic acid; a small portion ascends like a vapour, and is deposited in a white powder on the cold bodies with which it comes into contact; and in a dark place, toward the end of the operation, it shines with a bluish phosphoric light. It thus loses half its weight, and the magnesia is left quite pure.

As the magnesia of the shops is sometimes adulterated with chalk, this may be detected by the addition of a little sulphuric acid diluted with eight or ten times its weight of water, as this will form with the magnesia a very soluble salt, while the sulphate of lime will remain undissolved. Calcined magnesia should dissolve in this dilute acid without any effervescence.

The crystallised carbonate dissolves in forty-eight times its weight of cold water; the common carbonate requires at least ten times as much, and first forms a paste with a small quantity of the fluid.

The carbonate of ammonia, once vulgarly known by the name of *volatile sal ammoniac*, and abroad by that of *English volatile salt*, because it was first prepared in this country, was commonly called *mild volatile alkali*, before its true nature was known.

When very pure it is in a crystalline form, but seldom very regular. Its crystals are so small, that it is difficult to determine their figure. The taste and smell of this salt are the same with those of pure ammonia, but much weaker. It turns the colour of violets green, and that of turmeric brown. It is soluble in rather more than twice its weight of cold water, and in its own weight of hot water; but a boiling heat volatilizes it. When pure, and thoroughly saturated, it is not perceptibly alterable in the air; but when it has an excess of ammonia, it softens and grows moist. It cannot be doubted, however, that it is soluble in air; for if left in an open vessel, it gradually diminishes in weight, and its peculiar smell is diffused to a certain distance. Heat readily sublimes, but does not decompose it.

It has been prepared by the destructive distillation of animal substances, and some others, in large iron pots, with a fire increased by degrees to a strong red-heat, the aqueous liquor that first comes over being removed, that the salt might not be dissolved in it. Thus we had the *salt of hartshorn, salt of soot, essential salt of vipers*, &c. If the salt were dissolved in the water, it was called *spirit* of the substance from which it was obtained. Thus, however, it was much contaminated by a fœtid animal oil, from which it required to be subsequently purified, and is much better fabricated by mixing one part of muriate of ammonia and two of carbonate of lime, both as dry as possible, and subliming in an earthen retort.

Sir H. Davy has shown that its component parts vary, according to the manner of preparing it. The lower the temperature at which it is formed, the greater the proportion of acid and water. Thus, if formed at the temperature of 300°, it contains more than fifty per cent. of alkali; if at 60°, not more than twenty per cent.

There are three or four definite compounds of carbonic acid and *ammonia*.

The 1st is the solid *sub-carbonate* of the shops. It consists of 55 carbonic acid, 30 ammonia, and 15 water; or probably of 3 primes carbonic acid, 2 ammonia, and 2 water; in all 14.7 for its equivalent.

2d, Gay Lussac has shown, that when 100 volumes of ammoniacal gas are mixed with 50 of carbonic acid, the two gases precipitate in a solid salt, which must consist by weight of 56⅓ acid + 43⅔ alkali, being in the ratio of a prime equivalent of each.

3d, When the pungent sub-carbonate is exposed in powder to the air, it becomes scentless by the evaporation of a definite portion of its ammonia. It is then a compound of about 55 or 56 carbonic acid, 21.5 ammonia, and 22.5 water. It may be represented by 2 primes of acid, 1 of ammonia, and 2 of water, = 9.875.

Another compound, it has been supposed, may be prepared by passing carbonic acid through a solution of the sub-carbonate till it be saturated. This, however, may be supposed to yield the same product as the last salt. Lussac infers the neutral carbonate to consist of equal volumes of the two gases, though they will not directly combine in these proportions. This would give 18.1 to 46.5; the very proportions in the scentless salt. For 46.5 : 18.1 : : 55 : 21.42.

It is well known as a stimulant usually put into smelling bottles, frequently with the addition of some odoriferous oil.

Fourcroy has found, that an *ammoniaco-magnesian carbonate* is formed on some occasions. Thus, if carbonate of ammonia be decomposed by magnesia in the moist way, leaving these two substances in contact with each other in a bottle closely stopped, a complete decomposition will not take place, but a portion of this trisalt will be formed. The same will take place if a solution of carbonate of magnesia in water, impregnated with carbonic acid, be precipitated by pure ammonia; or if ammoniaco-magnesian sulphate, nitrate, or muriate, be precipitated by carbonate of potassa or of soda.

The properties of this triple salt are not much known, but it crystallises differently from the carbonate of either of its bases, and has its own laws of solubility and decomposition.

The carbonate of glucine is in a white, dull, clotty powder, never dry, but greasy, and soft to the feel. It is not sweet, like the other salts of glucine, but insipid. It is very light, insoluble in water, perfectly unalterable by the air, but very readily decomposed by fire. A saturated solution of carbonate of ammonia takes up a certain portion of this carbonate, and forms with it a triple salt.

Carbonic acid does not appear to be much disposed to unite with *argillaceous earth*. Most clays, however, afford a small quantity of this acid by heat. The snowy white substance resembling chalk, and known by the name of *lac lunæ*, is found to consist almost wholly of alumina saturated with carbonic acid. A saline substance, consisting of two six-sided pyramids, joined at one common base, weighing five or six grains, and of a taste somewhat resembling alum, was produced by leaving an ounce phial of water impregnated with carbonic acid, and a redundancy of alumina, exposed to spontaneous evaporation for some months.

Vauquelin has found, that *carbonate of zircone* may be formed by evaporating muriate of zircone, redissolving it in water, and precipitating by the alkaline carbonate. He also adds, that it very readily combines so as to form a triple salt, with either of the three alkaline carbonates."—*Ure's Chem. Dict.*

This gas is much esteemed in the cure of typhus fevers, and of irritability and weakness of stomach, producing vomiting. Against the former diseases it is given by administering yeast, bottled porter, and the like; and for the latter it is disengaged from the carbonated alkali by lemon juice in a draught given while effervescing.

CARBONIC OXIDE. Gaseous oxide of carbon. "A gaseous compound of one prime equivalent of carbon, and one of oxygen, consisting by weight of 0.75 of the former, and 1.00 of the latter. Hence the prime of the compound is 1.75, the same as that of azote. This gas cannot be formed by the chemist by the direct combination of its constituents; for at the temperature requisite for effecting a union, the carbon attracts its full dose of oxygen, and thus generates carbonic acid. It may be procured by exposing charcoal to a long continued heat. The last products consist chiefly of carbonic oxide.

To obtain it pure, however, our only plan is to abstract one proportion of oxygen from carbonic acid, either in its gaseous state, or as condensed in the carbonates.

If we subject to a strong heat, in a gun barrel or retort, a mixture of any dry earthy carbonate, such as chalk, or carbonate of strontites, with metallic filings or charcoal, the combined acid is resolved into the gaseous oxide of carbon. The most convenient mixture is equal parts of dried chalk and iron, or zinc filings.

The specific gravity of this gas is stated by Gay Lussac and Thenard, from theoretical considerations, to be 0.96782, though Mr. Cruikshank's experimental estimate was 0.9569.

This gas burns with a dark blue flame. Sir H. Davy has shown, that though carbonic oxide in its combustion produces less heat than other inflammable gases, it may be kindled at a much lower temperature. It inflames in the atmosphere, when brought into contact with an iron wire heated to dull redness, whereas carburetted hydrogen is not inflammable by a similar wire, unless it is heated to whiteness, so as to burn with sparks. It requires, for its combustion, half its volume of oxygen gas, producing one volume of carbonic acid. It is not decomposable by any of the simple combustibles, except potassium and sodium. When potassium is heated in a portion of the gas, potassa is formed with the precipitation of charcoal, and the disengagement of heat and light. Perhaps iron, at a high temperature, would condense the oxygen and carbon by its strong affinity for these substances. Water condenses $\frac{1}{50}$ of its bulk of the gas. The above processes are those usually prescribed in our systematic works, for procuring the oxide of carbon. In some of them, a portion of carbonic acid is evolved, which may be withdrawn by washing the gaseous product with weak solution of potassa, or milk of lime. We avoid the chance of this impurity by extricating the gas from a mixture of dry carbonate of barytes and iron filings, or of oxide of zinc, and previously calcined charcoal. The gaseous product from the first mixture, is pure oxide of carbon. Oxide of iron, and pure barytes, remain in the retort. Carbonic oxide, when respired, is fatal to animal life. Sir H. Davy took three inspirations of it, mixed with about one-fourth of common air; the effect was a temporary loss of sensation, which was succeeded by giddiness, sickness, acute pains in different parts of the body, and extreme debility. Some days elapsed before he entirely recovered. Since then, Mr. Witter of Dublin was struck down in an apoplectic condition, by breathing this gas; but he was speedily restored by the inhalation of oxygen. See an interesting account of this experiment, by Mr. Witter, in the Phil. Mag. vol. 43.

When a mixture of it and chlorine is exposed to sunshine, a curious compound, discovered by Dr. John Davy, is formed, to which he gave the name of phosgene gas. It has been called chlorocarbonic acid, though chlorocarbonous acid seems a more appropriate name."—*Ure's Chem. Dict.*

CARBUNCLE. 1. The name of a gem highly prized by the ancients, probably the *alamandine*, a variety of noble garnet.

2. The name of a disease. See *Anthrax*.

CARBU'NCULUS. (Diminutive of *carbo*, a burning coal.) A carbuncle. See *Anthrax*.

CARBURET. *Carburetum*. A combination of charcoal with any other substance: thus carburetted hydrogen is hydrogen holding carbon in solution; carburetted iron is steel, &c.

Carburet of sulphur. Sulphuret of carbon. Alcohol of sulphur. "This interesting liquid was originally obtained by Lampadius in distilling a mixture of pulverized pyrites and charcoal in an earthen retort, and was considered by him as a peculiar compound of sulphur and hydrogen. But Clement and Desormes first ascertained its true constitution to be carburetted sulphur; and they invented a process of great simplicity, for at once preparing it, and proving its nature. Thoroughly calcined charcoal is to be put into a porcelain tube, that traverses a furnace at a slight angle of inclination. To the higher end of the tube, a retort of glass, containing sulphur, is luted; and to the lower end is attached an adopter tube, which enters into a bottle with two tubulures, half full of water, and surrounded with very cold water or ice. From the other aperture of the bottle, a bent tube proceeds into the pneumatic trough. When the porcelain tube is brought into a state of ignition, heat is applied to the sulphur, which subliming into the tube, combines with the charcoal, forming the liquid carburet.

The carburet of sulphur dissolves camphor. It does not unite with water; but very readily with alkohol and æther. With chloride of azot it forms a non-detonating compound. The waters of potassa, barytes, and lime, slowly decompose it, with the evolution of carbonic acid gas. It combines with ammonia and lime, forming carbo-sulphurets. The carburet, saturated with ammoniacal gas, forms a yellow pulverulent substance, which sublimes unaltered in close vessels, but is so deliquescent that it cannot be passed from one vessel to another without absorbing moisture. When heated in that state, crystals of hydrosulphuret of ammonia form. The compound with lime is made by heating some quicklime in a tube, and causing the vapour of carburet to pass through it. The lime becomes incandescent at the instant of combination.

When the carburet is left for some weeks in contact with nitro-muriatic acid, it is converted into a substance having very much the appearance and physical properties of camphor; being soluble in alkohol and oils, and insoluble in water. This substance is, according to Berzelius, a triple acid, composed of two atoms of muriatic acid, one atom of sulphurous acid, and one atom of carbonic acid. He calls it, muriatico-sulphurous-carbonic acid.

When potassium is heated in the vapour of the carburet, it burns with a reddish flame, and a black film appears on the surface. On admitting water, a greenish solution of sulphuret of potassa is obtained, containing a mixture of charcoal. From its vapour passing through ignited muriate of silver, without occasioning any reduction of the metal, it is demonstrated that this carburet is destitute of hydrogen.

When the compound of potassa, water, and carburet of sulphur, is added to metallic solutions, precipitates of a peculiar kind, called carbo-sulphurets, are obtained.

Carburet of sulphur was found by Dr. Brewster to exceed all fluid bodies in refractive power, and even the solids, flint-glass, topaz, and tourmaline. In dispersive power it exceeds every fluid substance except oil of cassia, holding an intermediate place between phosphorus and balsam of Tolu."—*Ure.*

Carburetted hydrogen gas. *Carbonated Hydrogen gas; Heavy inflammable air; Hydro-carbonate. Olefiant gas. Hydroguret, of carbon.* "Of this compound gas we have two species, differing in the proportions of the constituents. The first, consisting of 1 prime equivalent of each, is carburetted hydrogen; the second, of 1 prime of carbon, and 2 of hydrogen, is subcarburetted hydrogen.

1. *Carburetted hydrogen*, the percarburetted of the French chemists, is, according to Mr. Brande, the only definite compound of these two elements. To prepare it, we mix, in a glass retort, 1 part of alkohol and 4 of sulphuric acid, and expose the retort to a moderate heat. The gas is usually received over water; though De Saussure states that this liquid absorbs more than 1-7th of its volume of the gas. It is destructive of animal life. Its specific gravity is 0.978, according to Saussure. 100 cubic inches weigh 28.80 gr. It possesses all the mechanical properties of air. It is invisible, and void of taste and smell, when it has been washed from a little æthereous vapour. The effect of heat on this gas is curious. When passed through a porcelain tube, heated to a cherry-red, it lets fall a portion of charcoal, and nearly doubles its volume. At a higher temperature it deposits more charcoal, and augments in bulk; till finally, at the greatest heat to which we can expose it, it lets fall almost the whole of its carbon, and assumes a volume 3½ times greater than it had at first. These remarkable results, observed with great care, have induced the illustrious Berthollet to conclude, with much plausibility, that hydrogen and carbon combine in many successive proportions. The transmission of a series of electric sparks through this gas produces a similar effect with that of simple heat.

Carburetted hydrogen burns with a splendid white flame. When mixed with three times its bulk of oxygen, and kindled by a taper or the electric spark, it explodes with great violence.

When this gas is mixed with its own bulk of chlorine, the gaseous mixture is condensed over water into a peculiar oily-looking compound. Hence this carburetted hydrogen was called by its discoverers, the associated Dutch chemists, *olefiant gas.* Robiquet and Colin formed this liquid in considerable quantities, by making two currents of its constituent gases meet in a glass globe. The olefiant gas should be in rather larger quantity than the chlorine, otherwise the liquid becomes of a green colour, and acquires acid properties. When it is washed with water, and distilled off dry muriate of lime, it may be regarded as pure. It is then a limpid colourless essence of a pleasant flavour, and a sharp, sweet, and not disagreeable taste. At 45° its specific gravity is 2.2201. Dr. Thompson calls this fluid *chloric æther*, and it may with propriety, Mr. Brande thinks, be termed *hydro-chloride of carbon.*

Olefiant gas is elegantly analysed by heating sulphur in it over mercury. One cubic inch of it, with 2 grains of sulphur, yields 2 cubic inches of sulphuretted hydrogen, and charcoal is deposited. Now we know that the latter gas contains just its own volume of hydrogen.

2. *Subcarburetted hydrogen.* This gas is supposed to be procured in a state of definite composition, from the mud of stagnant pools or ditches. We have only to fill a wide-mouthed goblet with water, and inverting it in the ditch-water, stir the bottom with a stick. Gas rises into the goblet.

The fire-damp of mines is a similar gas to that of ditches. There is in both cases an admixture of carbonic acid, which lime or potassa-water will remove. A proportion of air is also present, the quantity of which can be ascertained by analysis. By igniting acetate of potassa in a gun-barrel, an analogous species of gas is obtained.

Subcarburetted hydrogen is destitute of colour, taste, and smell. It burns with a yellow flame, like that of a candle.

As the gas of ditches and the choke-damp of mines is evidently derived from the action of water on decaying vegetable or carbonaceous matter, we can understand that a similar product will be obtained by passing water over ignited charcoal, or by heating moistened charcoal or vegetable matter in retorts. The gases are here, however, a somewhat complex mixture, as well as what we obtain by igniting pit coal and wood in iron retorts. The combustion of subcarburetted hydrogen with common air takes place only when they are mixed in certain proportions. If from 6 to 12 parts of air be mixed with one of carburetted hydrogen, we have explosive mixtures. Proportions beyond these limits will not explode. In like manner, from 1 to 2½ of oxygen must be mixed with one of the combustible gas, otherwise we have no explosion. Sir H. Davy says, that this gas has a disagreeable empyreumatic smell, and that water absorbs 1-30th of its volume of it."—*Ure.*

CA′RCARUS. (From *καρκαιρω*, to resound.) *Carcaros.* A fever in which the patient has a continual horror and trembling, with an unceasing sounding in his ears.

CA′RCAX. (From *καρα*, a head.) A species of poppy, with a very large head.

CA′RCER. A remedy, according to Paracelsus, for restraining the motions of body, the extravagant and libidinous conversation in some disorders; as in *Chorea Sancti Viti*, &c.

CARCHE′SIUS. *Καρχησιος.* The openings at the top of a ship's mast through which the rope passes. A name of some bandages noticed by Galen, and described by Oribasius.

CARCINO′MA. (*Carcinoma, atis.* n. From *καρκινος*, a cancer.) See *Cancer.*

CARCINUS. (Καρκινος, a cancer.) *Carcinos.* See *Cancer.*

CARDAMA′NTICA. (From *καρδαμον*, the nasturtium.) A species of sciatica cresses.

CARDAMELE′UM. A medicine of no note, mentioned by Galen.

CARDAMI′NE. (*Cardamine, es.* f.; from *καρδια*, the heart; because it acts as a cordial and strengthener, or from its having the taste of cardamum, that is, nasturtium, or cress.) Cuckoo-flower. 1. The name of a genus of plants in the Linnæan system. Class, *Tetradynamia;* Order, *Siliquosa.*

2. The pharmacopœial name of the cuckoo-flower. See *Cardamine pratensis.*

CARDAMINE PRATENSIS. The systematic name of the common ladies' smock, or cuckoo-flower, called *cardamine* in the pharmacopœias. *Cardamantica; Nasturtium aquaticum; Culi flos; Iberis sophia; Cardamine:—foliis pinnatis, foliolis, radicalibus subrotundis, caulinis lanceolatis* of Linnæus. The flower has a place in the materia medica, upon the authority of Sir George Baker, who has published five cases, two of chorea Sancti Viti, one of spasmodic asthma, one of hemiplegia, and a case of spasmodic affections of the lower limbs, wherein the *flores cardamines* were supposed to have been successfully used. A variety of virtues have been given to this plant, but it does not deserve the attention of practitioners.

CARDAMO′MUM. (From *κάρδαμον*, and *αμωμον*: because it partakes of the nature, and is like both the cardamum and amomum.) The cardamom. See *Amomum, Elettaria*, and *Illicium.*

CARDAMOMUM MAJUS. See *Amomum granum paradisi.*

CARDAMOMUM MEDIUM. The seeds correspond, in every respect, with the lesser, except in being twice as long, but no thicker than the *Cardamomum minus.*

CARDAMOMUM MINUS. See *Elettaria cardamomum.*

CARDAMOMUM PIPERATUM. See *Amomum granum paradisi.*

CARDAMOMUM SIBERIENSE. See *Illicium stellatum.*

CA′RDAMUM. (From *καρδια*, the heart; because it comforts and strengthens the heart.) The cardamum. See *Amomum, Elatteria*, and *Illicium.*

CA′RDIA. (From *κεαρ*, the heart.) 1. This term was applied by the Greeks to the heart.

2. The superior opening of the stomach.

CARDI′AC. (*Cardiacus;* from *καρδια*, the heart.) A cordial. See *Cordial.*

CARDIACA CONFECTIO. See *Confectio aromatica.*

CARDIACA HERBA. So named from the supposed relief it gives in faintings and disorders of the stomach. The pharmacopœial name of the plant called Mother-wort. See *Leonurus cardiaca.*

CARDIACA PASSIO. The cardiac passion. Ancient writers frequently mention a disorder under this name, which consists of that oppression and distress which often accompanies fainting.

CARDIACUS MORBUS. A name by which the ancients called the typus fever.

CARDIA′LGIA. (From *καρδια*, the cardia, and *αλγος*, pain.) Pain at the stomach. The heartburn. Dr. Cullen ranks it as a symptom of dyspepsia. Heartburn is an uneasy sensation in the stomach, with anxiety, a heat more or less violent, and sometimes attended with oppression, faintness, an inclination to vomit, or a plentiful discharge of clear lymph, like saliva. This pain may arise from various and different causes; such as *flatus;* from *sharp humours*, either acid, bilious, or rancid; from *worms* gnawing and vellicating the coats of the stomach; from *acrid* and *pungent food*, such as spices, aromatics, &c.; as also from *rheumatic* and *gouty humours*, or *surfeits;* from too free a use of tea, or watery fluids relaxing the stomach, &c.; *from the natural mucus* being abraded, particularly in the upper orifice of the stomach.

CARDIALGIA SPUTATORIA. See *Pyrosis.*

CARDIME′LECH. (From *καρδια*, the heart, and *meleck*, Heb. a governor.) A fictitious term in Dolæus's Encyclopedia, by which he would express a particular active principle in the heart, appointed to what we call the vital functions.

CARDIMO′NA. Pain at the stomach.

Cardinal flowers. See *Lobelia.*

CARDINAME′NTUM. (From *cardo*, a hinge.) An articulation like a hinge.

CARDIO′GMUS. (From *καρδιωσσω*, to have a pain in the stomach.) 1. A distressing pain at the præcordia or stomach.

2. An aneurism in or near the heart, which occasions pain in the præcordia.

3. A variety of the *Exangia aneurisma* of Good's nosological arrangement.

CARDIO′NCHUS. (From *καρδια*, the heart, and *ογκος*, a tumour.) An aneurism in the heart, or in the aorta near the heart.

CARDIOTRO′TUS. (From *καρδια*, the heart, and *τιτρωσκω*, to wound.) One who hath a wound in his heart.

CARDI′TIS. (From *καρδια*, the heart.) *Em-*

pressma carditis of Good. Inflammation of the heart. It is a genus of disease arranged by Cullen in the class *Pyrexiæ*, and order *Phlegmasiæ*. It is known by pyrexia, pain in the region of the heart, great anxiety, difficulty of breathing, cough, irregular pulse, palpitation, and fainting, and the other symptoms of inflammation.

The treatment of carditis is, in a great measure, similar to that of pneumonia. It is necessary to take blood freely, as well generally as locally, and apply a blister near the part. Purging may be carried to a greater extent than in pneumonia; and the use of digitalis is more important, to lessen the irritability of the heart. It is equally desirable to promote diaphoresis, but expectoration is not so much to be looked for, unless indeed, as very often happens, the inflammation should have extended, in some degree, to the lungs.

CA'RDO. A hinge. 1. The articulation called *Ginglymus*.

2. The second vertebra of the neck.

CARDO'NIUM. Wine medicated with herbs.—*Paracelsus*.

CARDOPA'TIUM. The low carline thistle. Most probably the *Carlina acaulis* of Linnæus, said to be diaphoretic.

CA'RDUUS. (*à carere, quasi aptus carendæ lanæ*, being fit to tease wool; or from κειρω, to abrade; so named from its roughness, which abrades and tears whatever it meets with.) The thistle or teasel. The name of a genus of plants in the Linnæan system. Class, *Syngenesia*; Order, *Polygamia æqualis*.

CARDUUS ACANTHUS. The bear's breech.

CARDUUS ALTILIS. The artichoke.

CARDUUS ARVENSIS. The way-thistle. See *Serratula arvensis*.

CARDUUS BENEDICTUS. See *Centaurea*.

CARDUUS HÆMORRHOIDALIS. The common creeping way-thistle. *Serratula arvensis* of Linnæus.

CARDUUS LACTEUS. See *Carduus marianus*.

CARDUUS MARIÆ. See *Carduus marianus*.

CARDUUS MARIANUS. The systematic name of the officinal *Carduus mariæ*. Common milk-thistle, or Lady's-thistle. *Carduus:—foliis amplexicaulibus, hastato-pinnatifidis, spinosis; calycibus aphyllis; spinis caliculatis, duplicato-spinosis*, of Linnæus. The seeds of this plant, and the herb, have been employed medicinally. The former contain a bitter oil, and are recommended as relaxants. The juice of the latter is said to be salutary in dropsies, in the dose of four ounces; and, according to Miller, to be efficacious against pungent pains. The leaves when young surpass, when boiled, the finest cabbage, and in that state are diuretic.

CARDUUS SATIVUS. The artichoke.

CARDUUS SOLSTITIALIS. The *Calcitrapa officinalis* of Linnæus.

CARDUUS TOMENTOSUS. The woolly thistle. See *Onopordium acanthium*.

CAREBA'RIA. (From καρη, the head, and βαρος, weight.) A painful and uneasy heaviness of the head.

CARE'NUM. (From καρη, the head.) Galen uses this word for the head.

CARENUM VINUM. Strong wine.

CAREUM. (From *Caria*, the country whence they were brought.) The caraway.

CA'REX. (*Carex, icis*. fœm. from *careo*, not *quia viribus careat*, but because, from its roughness, it is fit *ad carendum*, to card, tease, or pull.) Sedge. The name of a genus of plants in the Linnæan system. Class, *Monœcia*; Order, *Triandria*.

CAREX ARENARIA. The systematic name of the officinal *sarsaparilla germanica*, which grows plentifully on the sea coast. The root has been found serviceable in some mucal affections of the trachea, in rheumatic pains, and gouty affections. These roots, and those of the *carex hirta*, are mixed with the true sarsaparilla, which they much resemble.

CA'RICA. (From *Caria*, the place where they were cultivated.) The fig. See *Ficus carica*.

CARICA PATAYA. Papaw-tree. This is a native of both Indies, and the Guinea coast of Africa. When the roundish fruit are nearly ripe, the inhabitants of India boil and eat them with their meat, as we do turnips. They have somewhat the flavour of a pompion. Previous to boiling, they soak them for some time in salt and water, to extract the corrosive juice, unless the meat they are to be boiled with should be very salt and old, and then this juice being in them, will make them as tender as a chicken. But they mostly pickle the long fruit, and thus they make no bad succedaneum for mango. The buds of the female flowers are gathered, and made into a sweetmeat; and the inhabitants are such good husbands of the produce of this tree, that they boil the shells of the ripe fruit into a repast, and the insides are eaten with sugar in the manner of melons. Every part of the papaw-tree, except the ripe fruit, affords a milky juice, which is used, in the Isle of France, as an effectual remedy for the tape-worm. In Europe, however, whither it has been sent in the concrete state, it has not answered, perhaps from some change it had undergone, or not having been given in a sufficient dose.

A very remarkable circumstance regarding the papaw-tree, is the extraction from its juice of a matter exactly resembling the flesh or fibre of animals, and hence called vegetable fibrin.

CARICUM. (From *Caricus*, its inventor.) *Carycum*. An ointment for cleansing ulcers, composed of hellebore, lead, and cantharides.

CA'RIES. (From *carah*, Chald.) *Gangrena caries* of Good. Rottenness, mortification of the bones.

CARI'MA. The cassada bread.

CARI'NA. The keel of a ship. 1. A name formerly applied to the back bone.

2. In botany, the keel, or that part of the petals which compose a papilionaceous flower, consisting of two, united or separate, which embrace the internal or genital organs. See *Corolla*.

CARINATUS. Keel-shaped; applied to leaves and petals when the back is longitudinally prominent like the keel of a boat; as in the leaf of the *Allium carinatum*, and the petals of the *Allium ampelloprasum*, and *Carum carui*.

CARINTHINE. A subspecies of mineral augite found in Carinthia.

CARIOUS. When a part of a bone is deprived of its vitality, it is said to be carious, dead or rotten: hence carious tooth, &c.

CA'RIUM TERRA. Lime.

CARIVILLA'NDI. Sarsaparilla root.

CARLI'NA. (From *Carolus*, Charles the Great, or Charlemagne; because it was believed that an angel showed it to him, and that, by the use of it, his army was preserved from the plague.) Carline thistle. The name of a genus of plants in the Linnæan system. Class, *Syngenesia*; Order, *Polygamia æqualis*. The officinal name of two kinds of plants.

CARLINA ACAULIS. The systematic name of the *chamæleon album. Carlina; Cardopatium.* Carline thistle. Star thistle. *Carlina—caule unifloro, flore breviore,* of Linnæus. The root of this plant is bitter, and said to possess diaphoretic and anthelmintic virtues. It is also extolled by foreign physicians in the cure of acute, malignant, and chronic disorders, particularly gravel and jaundice.

CARLINA GUMMIFERA. *Carduus pinea; Ixine.* Pine thistle. This plant is the *Atractylis gummifera* of Linnæus. The root, when wounded, yields a milky, viscous juice, which concretes into tenacious masses, at first whitish, resembling wax, when much handled growing black; it is said to be chewed with the same views as mastich.

Carline thistle. See *Carlina acaulis.*

CA'RLO SANCTO RADIX. St. Charles's root; so called by the Spaniards, on account of its great virtues. It is found in Mechoachan, a province in America. Its bark hath an aromatic flavour, with a bitter acrid taste. The root itself consists of slender fibres. The bark is sudorific, and strengthens the gums and stomach.

CA'RMEN. (*Carmen, inis.* neut. A verse; because charms usually consisted of a verse.) A charm; an amulet.

CARMES. (The Carmelite friars, Fr.) Carmelite water; so named from its inventors; composed of baum, lemon-peel, &c.

CARMINA'NTIA. See *Carminative.*

CARMI'NATIVE. (*Carminativus;* from *carmen,* a verse, or charm; because practitioners, in ancient times, ascribed their operation to a charm or enchantment.) That which allays pain and dispels flatulencies of the primæ viæ. The principal carminatives are the semina cardamomi, anisi et carui; olea essentialia carui, anisi et juniperi; confectio aromatica; pulvis aromaticus; tinctura cardamomi; tinctura cinnamomi composita; zingiber; stimulants; tonics; bitters; and astringents.

CARMINE. A red pigment prepared from cochineal.

CARMINIUM. The name given by the French chemists to the colouring matter of cochineal. See *Coccus cacti.*

CARNABA'DIUM. Caraway-seed.

CA'RNEA COLUMNA. A fleshy pillar or column. The name of some fleshy fasiculi in the ventricles of the heart. See *Heart.*

CARNELIAN. A subspecies of calcedony.

CARNI'CULA. (Diminutive of *caro, carnis,* flesh.) A small fleshy substance; applied to the substance which surrounds the gums.

CARNIFO'RMIS. (From *caro,* flesh, and *forma,* likeness.) Having the appearance of flesh. It is commonly applied to an abscess where the flesh surrounding the orifice is hardened, and of a firm consistence.

CARNOSUS. Fleshy; applied to leaves, pods, &c. of a thick pulpy substance; as in the leaves of all those plants called succulent, especially *sedum, crassula, &c.*

CA'RO. (*Caro, carnis.* fœm.) 1. Flesh. The red part or belly of a muscle.

2. The pulp of fruit.

CAROLI'NA. See *Carlina.*

CAROMEL. The smell exhaled from sugar at the calcining heat.

CARO'PI. The *Amomum verum.*

CARO'RA. A chemical vessel that resembles an urinal.

CARO'SIS. See *Carus.*

CARO'TA. See *Daucus.*

CAROTID. (From καροω, to cause to sleep; because, if tied with a ligature, the animal becomes comatose, and has the appearance of being asleep.) An artery of the neck. See *Carotid artery.*

CAROTID ARTERY. *Arteria carotidea.* The carotids are two considerable arteries that proceed, one on each side of the cervical vertebræ, to the head, to supply it with blood. The right carotid does not arise immediately from the arch of the aorta, but is given off from the arteria innominata. The left arises from the arch of the aorta. Each carotid is divided into external and internal, or that portion without and that within the cranium. The external gives off eight branches to the neck and face, viz. *anteriorly,* the superior thyroideal, the sublingual, the inferior maxillary, the external maxillary; *posteriorly,* the internal maxillary, the occipital, the external auditory, and the temporal. The internal carotid or cerebral artery, gives off four branches within the cavity of the cranium; the anterior cerebral, the posterior, the central artery of the optic nerve, and the internal orbital.

CARO'UM. The caraway seed.

CA'RPASUS. (So named ϖαρα το καρον ποιησαι: because it makes the person who eats it appear as if he was asleep.) A herb, the juice of which was formerly called *opocarpason, opocarpathon,* or *opocalpason;* according to Galen, it resembles myrrh; but is esteemed highly poisonous.

CARPA'THICUM BALSAMUM. See *Pinus Cembra.*

CARPENTA'RIA. (From *carpentarius,* a carpenter; and so named from its virtues in healing cuts and wounds made by a tool.) A vulnerary herb; not properly known what it is, but believed to be the common milfoil or yarrow, the *Achillæa millifolium* of Linnæus.

CARPHA'LEUS. (From καρφω, to exsiccate.) Hippocrates uses this word to mean *dry,* opposed to *moist.*

CARPHOLO'GIA. (From καρφος, the nap of clothes, and λεγω, to pluck.) *Carpologia.* A delirious picking of the bed-clothes, a symptom of great danger in diseases. See *Floccilatio.*

CA'RPHUS. (From καρφη, a straw.) 1. In Hippocrates it signifies a mote, or any small substance.

2. A pustule of the smallest kind.

3. The herb fenugreek.

CA'RPIA. (From *carpo,* to pluck, as lint is made from linen cloth.) Lint.

CARPI'SMUS. The wrist.

CARPOBA'LSAMUM. (From καρπος, fruit, and βαλσαμον, balsam.) See *Amyris gileadensis.*

CARPOLO'GIA. See *Carphologia.*

CARPOTICA. (*Carpoticus;* from καρπωσις, *fruitio,* from καρπος, *fructus.*) The name of an order of diseases in the class *Genetica* of Good's Nosology; diseases afflicting the impregnation. It embraces four genera. 1. *Paracyesis,* morbid pregnancy. 2. *Parodynia,* morbid labour. 3. *Eccyesis,* extra-uterine fœtation. 4. *Pseudocyesis,* spurious pregnancy.

CA'RPUS. (Καρπος, the wrist.) The wrist, or carpus. It is situated between the fore-arm and hand. See *Bone.*

CARROT. See *Daucus carota.*

Carrot, candy. See *Athamanta Cretensis.*

Carrot poultice. See *Cataplasma dauci.*

CA'RTHAMUS. (From καθαιρω, to purge.) 1. The name of a genus of plants in the Linnæan system. Class, *Syngenesia;* Order, *Polygamia æqualis.*

2. The pharmacopœial name of the saffron flower. See *Carthamus tinctorius.*

Carthamus tinctorius. The systematic name of the saffron flower, or bastard saffron, called also *Cnicus; Crocus saracenicus; Carthamum officinarum; Carduus sativus. Carthamus—foliis ovatis, integris, serrato-aculeatis* of Linnæus. The seeds, freed from their shells, have been celebrated as a gentle cathartic, in the dose of one or two drachms. They are also supposed to be diuretic and expectorant; particularly useful in humoral asthma, and similar complaints. The *carthamus lanatus* is considered in France as a febrifuge and sudorific. The dried flowers are frequently mixed with saffron, to adulterate it. The plant is cultivated in many places on account of its flowers, which are used as a dye.

"In some of the deep reddish, yellow, or orange-coloured flowers, the yellow matter seems to be of the same kind with that of the pure yellow flowers; but the red to be of a different kind from the pure red ones. Watery menstrua take up only the yellow, and leave the red, which may afterward be extracted by alkohol, or by a weak solution of alkali. Such particularly are the saffron-coloured flowers of carthamus. These, after the yellow matter has been extracted by water, are said to give a tincture to ley; from which, on standing at rest for some time, a deep red fecula subsides called safflower, and from the countries whence it is commonly brought to us, Spanish red and China lake. This pigment impregnates alcohol with a beautiful red tincture; but communicates no colour to water.

Rouge is prepared from carthamus. For this purpose the red colour is extracted by a solution of the subcarbonate of soda, and precipitated by lemon juice previously depurated by standing. This precipitate is dried on earthen plates, mixed with talc, or French chalk, reduced to a powder by means of the leaves of shave-grass, triturated with it till they are both very fine, and then sifted. The fineness of the powder and proportion of the precipitate constitute the difference between the finer and cheaper rouge. It is likewise spread very thin on saucers, and sold in this state for dyeing.

Carthamus is used for dyeing silk of a poppy, cherry, rose, or bright orange-red. After the yellow matter is extracted as above, and the cakes opened, it is put into a deal trough, and sprinkled at different times with pearl ashes, or rather soda, well powdered and sifted, in the proportion of six pounds to a hundred, mixing the alkali well as it is put in. The alkali should be saturated with carbonic acid. The carthamus is then put on a cloth in a trough with a grated bottom, placed on a larger trough, and cold water poured on, till the large trough is filled. And this is repeated, with the addition of a little more alkali toward the end, till the carthamus is exhausted and become yellow. Lemon juice is then poured into the bath, till it is turned of a fine cherry colour, and after it is well stirred, the silk is immersed in it. The silk is wrung, drained, and passed through fresh baths, washing and drying after every operation, till it is of a proper colour; when it is brightened in hot water and lemon juice. For a poppy or fire colour a slight annotto ground is first given; but the silk should not be alumed. For a pale carnation a little soap should be put into the bath. All these baths must be used as soon as they are made; and cold, because heat destroys the colour of the red feculæ."

CARTHEUSER, John Frederick, a professor of medicine at Francfort, on the Oder, acquired considerable reputation about the middle of the last century, by several luminous works on botany and pharmacy; especially his "Rudimenta Materiæ Medicæ Rationalis," and "De Genericis quibusdam Plantarum Principiis." He had two sons, Frederick Augustus and William, also of the medical profession, and authors of some less important works.

Carthusia'nus. (From the Monks of that order, who first invented it.) A name of the precipitated sulphur of antimony.

CARTILAGE. See *Cartilago.*

CARTILAGINEUS. Cartilagnious. 1. Applied, in anatomy, to parts which naturally, or from disease, have a cartilaginous consistence.

2. In botany, to leaves which have a hard or horny leaf-edge, as in several species of saxifrage. See *Leaf.*

CARTILA'GO. (*Cartilago, inis.* fœm. Quasi *carnilago;* from *caro, carnis,* flesh.) A white elastic, glistening substance, growing to bones, and commonly called *gristle.* Cartilages are divided, by anatomists, into *obducent,* which cover the moveable articulations of bones; *interarticular,* which are situated between the articulations, and *uniting* cartilages, which unite one bone with another. Their use is to facilitate the motions of bones, or to connect them together.

The chemical analysis of cartilage affords one-third the weight of the bones, when the calcareous salts are removed by digestion in dilute muriatic acid. It resembles coagulated albumen. Nitric acid converts it into gelatin. With alkalies it forms an animal soap. Cartilage is the primitive paste, into which the calcareous salts are deposited in the young animal. In the disease rickets, the earthy matter is withdrawn by morbid absorption, and the bones return into the state nearly of flexible cartilage. Hence arise the distortions characteristic of this disease.

Cartilago annularis. See *Cartilago cricoidea.*

Cartilago arytænoidea. See *Larynx.*

Cartilago cricoidea. The cricoid cartilage belongs to the larynx, and is situated between the thyroid and arytenoid cartilages and the trachea; it constitutes, as it were, the basis of the many annular cartilages of the trachea.

Cartilago ensiformis. *Cartilago xiphoidea.* Ensiform cartilage. A cartilage shaped somewhat like a sword or dagger, attached to the lowermost part of the sternum, just at the pit of the stomach.

Cartilago scutiformis. See *Thyroid cartilage.*

Cartilago thyroidea. See *Thyroid cartilage.*

Cartilago xiphoidea. See *Cartilago ensiformis.*

CA'RUI. (*Caruia.* Arabian.) The caraway. See *Carum.*

CA'RUM. (Καρος; so named from *Caria,* a province of Asia.) The Caraway. 1. The name of a genus of plants in the Linnæan system. Class *Pentandria;* Order, *Monogynia.*

2. The pharmacopœial name of the caraway plant. See *Carum carui.*

Carum carui. The systematic name for the plant, the seeds of which are called caraways. It is also called *Carvi; Cuminum pratense; Carus; Caruon.* The seeds are well known to have a pleasant spicy smell, and a warm aromatic taste; and, on this account, are used for various economical purposes. They are esteemed to be carminative, cordial, and stomachic, and recommended in dyspepsia, flatulencies, and other symptoms attending hysterical, and hypocondriacal disorders. An essential oil and distilled water are directed to be prepared from them by the London College.

CA′RUNCLE. (*Caruncula; diminutive of caro*, flesh.) *Ecphynia caruncula* of Good. A little fleshy excrescence; as the carunculæ myrtiformes, carunculæ lachrymales, &c.

CARUNCULA. See *Caruncle.*

Caruncula lachrymalis. A long conoidal gland, red externally, situated in the internal canthus of each eye, before the union of the eyelids. It appears to be formed of numerous sebaceous glands, from which many small hairs grow. The hardened smegma observable in this part of the eye in the morning, is separated by this caruncle.

Carunculæ mamillares. The extremities of the tubes in the nipple.

Carunculæ myrtiformes. When the hymen has been lacerated by attrition, there remain in its place, two, three, or four caruncles, which have received the name of myrtiform.

Carunculæ papillares. The protuberances within the pelvis of the kidney, formed by the papillous substance of the kidney.

Ca′ruon. See *Carum.*

CA′RUS. (Καρος; from καρα, the head, as being the part affected.) *Caros; Carosis.* 1. Insensibility and sleepiness, as in apoplexy, attended with quiet respiration.

2. A lethargy, or a profound sleep, without fever.

3. Dr. Good gives this name to a genus in his Nosology, embracing those diseases characterised by muscular immobility; mental or corporeal torpitude, or both. It has six species; *Carus asphyxia; ecstasis; catalepsia; lethargus; apoplexia; paralysis.*

4. The caraway seed.

Ca′rva. The cassia lignea.

Cary′don. See *Caryedon.*

Carye′don. (From καρυα, a nut.) *Carydon.* A sort of fracture, where the bone is broken into small pieces, like the shell of a cracked nut.

Caryocosti′num. An electuary; so named from two of its ingredients, the clove and costus.

CARYOPHYLLA′TA. (From καρυοφυλλον, the caryophyllus; so named, because it smells like the caryophyllus, or clove July flower.) See *Geum urbanum.*

Caryophylloi′des cortex. See *Laurus culilawan.*

CARYOPHY′LLUM. (Καρυοφυλλον; from καρυον, a nut, and φυλλον, a leaf; so named because it was supposed to be the leaf of the Indian nut.) The clove. See *Eugenia caryophyllata.*

Caryophyllum aromaticum. See *Eugenia caryophyllata.*

Caryophillum rubrum. The clove pink. See *Dianthus caryophyllus.*

CARYOPHY′LLUS. The clove-tree. The name of a genus of plants in the Linnæan system. Class, *Polyandria;* Order, *Monogynia.* See *Eugenia carophyllata.*

Caryophyllus aromaticus americanus. See *Myrtus pimenta.*

Caryophyllus hortensis. See *Dianthus caryophyllus.*

Caryophyllus vulgaris. See *Geum urbanum.*

Caryo′tis. (From καρυον, a nut.) *Caryota.* Galen gives this name to a superior sort of date, of the shape of a nut.

CASCARI′LLA. (Diminutive of *cascara*, the bark, or shell. Spanish.) A name given originally to small specimens of cinchona; but now applied to another bark. See *Croton cascarilla.*

Cas′chu. See *Acacia catechu.*

Cashew-nut. See *Anacardium occidentale.*

Cashow. See *Acacia catechu.*

CASEIC ACID. *Acidum caseicum.* The name given by Proust to an acid formed in cheeses, to which he ascribes their flavour.

Ca′sia. See *Cassia.*

Casmina′ris. See *Cassumuniar.*

Ca′ssa. (Arabian.) The breast.

CASSA′DA. See *Jatropha manihot.*

Ca′ssamum. The fruit of the balsam of Gilead tree, or *Amyrus opobalsamum.*

Ca′ssava. See *Jatropha manihot.*

CASSEBOHM, Frederic, a professor of anatomy at Halle in Saxony, published in 1730, a treatise on the difference between the Fœtus and Adult, in which he notices the descent of the testicle from the abdomen; and four years after a very minute and exact description of the ear. He likewise explained in subsequent publications the manner of dissecting the muscles and the viscera; but an early death prevented his completing his design of elucidating the anatomy of the whole body in the same way.

CASSERIUS, Julius, was born of humble parents at Placentia in 1545. He became servant to Fabricius at Padua, who observing his talent, first taught him anatomy, then made him his assistant, and finally coadjutor in the professorship in 1609. He pursued the study with uncommon zeal, expending almost all his profits in procuring subjects, and in having drawings and prints made of the parts, which he discovered, or traced more accurately than his predecessors. He employed comparative anatomy, not as a substitute for, but only as a clue to that of the human subject. He published an account of the organs of voice and hearing, which he afterwards extended to the other senses, explaining also the uses of these parts. Some years after his death in 1616, the rest of his plates, amounting to 78, with the explanations, were published with the works of Spigelius.

CA′SSIA. (From the Arabic *katsia*, which is from *katsa*, to tear off; so called from the act of stripping the bark from the tree.) The name of a genus of plants in the Linnæan system. Class, *Decandria;* Order, *Monogynia.*

Cassia bark. See *Laurus cassia.*

Cassia caryophyllata. The clove-bark tree. See *Myrtus caryophyllata.*

Cassia fistula. *Cassia nigra; Cassia fistularis; Alexandrina; Chaiarxambar; Canna; Cassia solutiva; Tlai Xiem.* The purging cassia. This tree, *Cassia—foliis quinquejugis ovatis acuminatis glabris, petiolis eglandulatis* of Linnæus, is a native of both Indies. The pods of the East India cassia are of a less diameter, smoother, and afford a blacker, sweeter, and more grateful pulp, than those which are brought from the West Indies. Those pods which are the heaviest, and in which the seeds do not rattle on being shaken, are commonly the best, and contain the most pulp, which is the part medicinally employed, and to be obtained in the manner described in the pharmacopœias. The best pulp is of a bright shining black colour, and of a sweet taste, with a slight degree of acidity. It has been long used as a laxative medicine, and being gentle in its operation, and seldom disturbing the bowels, is well adapted to children, and to delicate or pregnant women. Adults, however, find it of little effect, unless taken in a very large dose, as an ounce or more; and, therefore, to them this pulp is rarely given, but usually conjoined with some of the brisker purgatives. The officinal preparation of this drug, is the confectio cassiæ: it is also an ingredient in the confectio sennæ.

Cassia fistularis. See *Cassia fistula.*

Cassia latinorum. See *Osyris.*

CASSIA LIGNEA. See *Laurus cassia.*

CASSIA MONSPELIENSIUM. See *Osyris.*

CASSIA NIGRA. See *Cassia fistula.*

CASSIA POETICA. Poets' rosemary; a plant which grows in the south of Europe, and is said to be astringent. See *Osyris.*

Cassia, purging. See *Cassia fistula.*

CASSIA SENNA. The systematic name of the plant which affords senna. *Senna alexandrina; Senna italica.* Senna, or Egyptian cassia. *Cassia—foliis sejugis subovatis, petiolis eglandulatis* of Linnæus. The leaves of senna, which are imported here from Alexandria for medicinal use, have a rather disagreeable smell, and a subacrid, bitterish, nauseous taste. They are in common use as a purgative. The formulæ given of the senna by the colleges, are an infusion, a compound powder, a tincture, and an electuary. See *Infusum sennæ,* &c.

CASSIA SOLUTIVA. See *Cassia fistula.*

CASSIÆ ARAMENTUM. The pulp of cassia.

CASSIÆ FLORES. What are called cassia flowers in the shops, are the flowers of the true cinnamon-tree, *Laurus cinnamomum* of Linnæus. They possess aromatic and adstringent virtues, and may be successfully employed in decoctions, &c. in all cases where cinnamon is recommended. See *Laurus cinnamomum.*

CASSIÆ PULPA. See *Cassia fistula.*

Cassius's precipitate. The purple powder, which forms on a plate of tin immersed in a solution of gold. It is used to paint in enamel.

CA'SSOB. An obsolete term for kali.

CASSOLETA. Warm fumigations described by Marcellus.

CASSONADA. Sugar.

CASSUMMU'NIAR. (Of uncertain derivation; perhaps Indian.) *Casamunar; Casmina; Risagon; Bengale Indorum.* The root, occasionally exhibited under one of these names, is brought from the East Indies. It comes over in irregular slices of various forms, some cut transversely, others longitudinally. The cortical part is marked with circles of a dusky brown colour: the internal part is paler, and unequally yellow. It possesses moderately warm, bitter, and aromatic qualities, and a smell like ginger. It is recommended in hysterical, epileptic, and paralytic affections.

CASTA'NEA. (Καςανον; from *Castana,* a city in Thessaly, whence they were brought.) See *Fagus castanea.*

CASTANEA EQUINA. The horse-chesnut. See *Æsculus hippocastanum.*

CASTELLANUS, PETER, or DU CHATEL, was born at Grammont, in Flanders, 1585. His rapid improvement in the Greek language procured him the professorship, at Lovain, in 1609; but he did not graduate in medicine till nine years after. At the same period, he published the lives of eminent physicians in Latin, written in a concise but very entertaining manner, with useful references to the original authorities. He died in 1632.

CASTELLUS, BARTHOLOMEW, an Italian physician, who practised at Messina about the end of the 16th century. He was author of two works, both for a long time extremely popular, a Synopsis of Medicine, and "Lexicon Medicum Græco-Latinum," in which great learning and judgment are conspicuous.

CASTJOE. See *Acacia catechu.*

CASTLE-LEOD. The name of a place in Ross-shire, in Scotland, where there is a sulphureous spring, celebrated for the cure of cutaneous diseases and foul ulcers.

CASTOR. (*Castor;* from κας ωρ, the beaver, *quasi* γαςωρ; from γαςηρ, the belly: because of the largeness of its belly; or *à castrando,* because he was said to castrate himself in order to escape the hunters.)

1. The name of a genus of animals.

2. The English name of the *Castoreum* of the pharmacopœias, a peculiar contrete substance obtained from the Castor fiber of Linnæus. See *Castor fiber.*

CASTOR FIBER. The systematic name of the beaver, an amphibious quadruped inhabiting some parts of Prussia, Russia, Germany, &c.; but the greatest number of these animals is met with in Canada. The name of *castoreum* or castor is given to two bags, situated in the inguinal regions of the beaver, which contain a very odorous substance, soft, and almost fluid when recently cut from the animal, but which dries, and assumes a resinous consistence in process of time. The best comes from Russia. It is of greyish yellow, or light brown colour. It consists of a mucilage, a bitter extract, a resin, an essential oil, in which the peculiar smell appears to reside, and a flaky crystalline matter, much resembling the adipocire of biliary calculi. Castor has an acrid, bitter, and nauseous taste; its smell is strong and aromatic, yet at the same time fœtid. It is used medicinally, as a powerful antispasmodic in hysterica and hypochondriacal affections, and in convulsions, in doses of from 10 to 30 grains. It has also been successfully administered in epilepsy and tetanus. It is occasionally adulterated with dried blood, gum-ammoniacum, or galbanum, mixed with a little of the powder of castor, and some quantity of the fat of the beaver.

Castor oil. See *Ricinus.*

Castor, Russian. See *Castor fiber.*

CASTOREUM. See *Castor fiber.*

CASTORI'UM. See *Castoreum.*

CASTRATION. (*Castratio, onis.* f.; from *castro,* to emasculate, *quia castrando vis libidinis extinguitur.*) 1. A chirurgical operation, by which a testicle is removed from the body.

2. Botanists apply this term to the removal of the anthera of a flower, and to a plant naturally wanting this organ.

CASTRE'NSIS. (From *castra,* a camp.) Belonging to a camp: applied to those diseases with which soldiers, encamped in marshy places, are afflicted.

CATA'BASIS. (From καπαβαινω, to descend.) An operation downwards.

CATABI'BASIS. (From καταβιβαζω, to cause to descend.) An expulsion of the humours downwards.

CATABLACEU'SIS. (From καταβλακευω, to be useless.) Hippocrates uses this word to signify carelessness and negligence in the attendance on and administration to the sick.

CATABLE'MA. (From καταβαλλω, to throw round.) The outermost fillet, which secures the rest of the bandages.

CATABRONCHE'SIS. (From κατα, and βρογχος, the throat; or, καταβρογχιζω, to swallow.) The act of swallowing.

CATACAU'MA. (From κατακαιω, to burn.) A burn or scald.

CATACAU'SIS. (From κατακαιω, to burn.) 1. The act of combustion, or burning.

2. The name of a genus of diseases in Dr. Good's Nosology: general combustibility of the body. It has only one species, *Catacausis ebriosa.*

CATACECLI'MENUS. (From κατακλινομαι, to lie down.) Keeping the bed, from the violence of a disease.

CATACECRA'MENUS. (From κατακεραν-

νομι, to reduce to small particles.) Broken into small pieces: applied to fractures.

CATACERA′STICA. (From *καταχεραννυμι*, to mix together.) Medicines which obtund the acrimony of humours, by mixing with them and reducing them.

CATACHLIDE′SIS. (From *καταχλιδαω*, to indulge in delicacies.) A gluttonous indulgence in sloth and delicacies, to the generation of diseases.

CATACHRI′SMA. An ointment.

CATACHRI′STON. (From *καταχριω*, to anoint.) An ointment.

CATA′CLASIS. (From *κατακλαω*, to break, or distort.) Distorted eyelids.

CA′TACLEIS. (From *κατα*, beneath, and *κλεις*, the clavicle.) *Catacleis*. The subclavicle, or first rib, which is placed immediately under the clavicle.

CATACLI′NES. (From *κατακλινω*, to lie down.) One who, by disease, is fixed to his bed.

CATA′CLISIS. (From *κατακλινω*, to lie down.) A lying down. Also incurvation.

CATACLY′SMA. (From *κατακλυζω*, to wash.) A clyster.

CATACLY′SMUS. (From *κατακλυζω*, to wash.) 1. An embrocation.

2. A dashing of water upon any part.

CATACRE′MNOS. (From *κατα*, and *κρημνος*, a precipice.) Hippocrates means, by this word, a swoln and inflamed throat, from the exuberance of the parts.

CATACRU′SIS. (From *κατακρουω*, to drive back.) A revulsion of humours.

CATADOULE′SIS. (From *καταδουλοω*, to enslave.) The subduing of passions, as in a phrensy, or fever.

CATÆGIZE′SIS. (From *καταιγιζω*, to repel.) A revulsion or rushing back of humours, or wind in the intestines.

CATÆONE′SIS. (From *καταιονεω*, to irrigate.) Irrigation by a plentiful affusion of liquor on some part of the body.

CATA′GMA. (From *κατα*, and *αγω*, to break.) A fracture. Galen says a solution of the bone is called *catagma*, and *elcos* is a solution of the continuity of the flesh: that when it happens to a cartilage, it has no name, though Hippocrates calls it *catagma*.

CATAGMA′TICA. (From *καταγμα*, a fracture.) Catagmatics. Remedies which promote the formation of callus.

CATAGO′GE. (From *καταγομαι*, to abide.) The seat or region of a disease or part.

CATAGYIO′SIS. (From *καταγυιοω*, to debilitate.) An imbecility and enervation of the strength and limbs.

CATALE′PSIS. (From *καταλαμβανω*, to seize, to hold.) *Catoche; Catochus; Congelatio; Detentio; Encatalepsis;* by Hippocrates, *Aphonia;* by Antigenes, *Anaudia;* by Cœlius Aurelianus, *Apprehensio; Oppressio; Comprehensio; Carus catalepsia* of Good; *Apoplexia cataleptica* of Cullen. Catalepsy. A sudden suppression of motion and sensation, the body remaining in the same posture that it was in when seized.

Dr. Cullen says, he has never seen the catalepsy except when counterfeited; and is of opinion, that many of those cases related by other authors, have also been counterfeited. It is said to come on suddenly, being only preceded by some languor of body and mind, and to return by paroxysms. The patients are said to be for some minutes, sometimes (though rarely) for some hours, deprived of their senses, and all power of voluntary motion; but constantly retaining the position in which they were first seized, whether lying or sitting; and if the limbs be put into any other posture during the fit, they will keep the posture in which they are placed. When they recover from the paroxysm, they remember nothing of what passed during the time of it, but are like persons awakened out of a sleep.

CATALO′TICA. (From *καταλοαω*, to grind down.) Medicines to soften and make smooth the rough edges and crust of cicatrices.

CATA′LYSIS. (*Καταλυσις*: from *καταλυω*, to dissolve or destroy.) It signifies a palsy, or such a resolution as happens before the death of the patient; also that dissolution which constitutes death.

CATAMARA′SMUS. (From *ϖαταμαραινω*, to grow thin.) 1. An emaciation of the body.

2. The resolution of tumours.

CATAMASSE′SIS. (From *καταμασσομαι*, to manducate.) The grinding of the teeth, and biting of the tongue; common in epilepsy.

CATAME′NIA. (*Catamenia, orum.* neut. plur.; from *κατα*, according to, and *μην*, the month.) *Menses*. The monthly discharge from the uterus of females, between the ages of 14 and 45. Many have questioned whether this discharge arose from a mere rupture of vessels, or whether it was owing to a secretory action. There can be little doubt of the truth of the latter. The secretory organ is composed of the arterial vessels situated in the fundus of the uterus. The dissection of women, who have died during the time of their menstruating, proves this. Sometimes, though very rarely, women, during pregnancy, menstruate; and when this happens, the discharge takes place from the arterial vessels of the vagina. During pregnancy and lactation, when the person is in good health, the catamenia, for the most part, cease to flow. The quantity a female menstruates at each time is very various; depending on climate, and a variety of other circumstances. It is commonly in England from five to six ounces; it rarely exceeds eight. Its duration is from three to four, and sometimes, though rarely, five days. With respect to the nature of the discharge, it differs very much from pure blood; it never coagulates; but is sometimes grumous, and membranes like the decidua are formed in difficult menstruations: in some women it always smells rank and peculiar; in others it is inodorous. The use of this monthly secretion is said to be to render the uterus fit for the conception and nutrition of the fœtus; therefore girls rarely conceive before the catamenia appear, and women rarely after their entire cessation; but very easily soon after menstruation.

CATANA′NCE. Succory.

CATANI′PHTHIS. (From *κατανιπτω*, to wash.) Washed, or scoured. Used by Hippocrates of a diarrhœa washed and cleansed by boiled milk.

CATANTLE′MA. (From *καταντλαω*, to pour upon.) A lotion by infusion of water, or medicated fluids.

CATANTLE′SIS. A medicated fluid.

CATAPA′SMA. (From *καταπασσω*, to sprinkle.) *Catapastum; Conspersio; Epipaston; Pasma; Sympasma; Aspersio; Aspergo.* The ancient Greek physicians meant by this, any dry medicine reduced to powder, to be sprinkled on the body. Their various forms and uses may be seen in Paul of Egina, lib. vii. cap. xiii.

CATAPAU′SIS. (From *καταπαυω*, to rest or cease.) That rest or cessation from pain which proceeds from the resolution of uneasy tumours.

CATAPE′LTES. (From *κατα*, against, and *ϖελτη*, a shield.) 1. This word means a sling, a granado, or battery.

2. It was formerly used to signify the medicine which heals the wounds and bruises made by such an instrument.

CATA'PHORA. (From *καταφερω*, to make sleepy.) A preternatural propensity to sleep; a mild apoplexy; a species of Dr. Good's *Carus lethargus;* remissive lethargy.

Catapra'cta. (From *καταφρασσω*, to fortify.) A bandage on the thorax.

CATAPLA'SMA. (*Cataplasma matis.* neut.; from *καταπλασσω*, to spread like a plaster.) A poultice. The following are among the most useful:—

Cataplasma acetosæ. Sorrel poultice. The leaves are to be beaten in a mortar into a pulp. A good application to scorbutic ulcers.

Cataplasma aeratum. See *Cataplasma fermenti.*

Cataplasma aluminis. This application was formerly used to inflammation of the eyes, which was kept up from weakness of the vessels; it is now seldom used, a solution of alum being mostly substituted.

Cataplasma conii. Hemlock poultice. ℞. Conii foliorum exsiccatorum ℥j. Aquæ fontanæ, ℔ij. To be boiled till only a pint remains, when as much linseed-meal as necessary is to be added. This is an excellent application to many cancerous and scrophulous ulcers, and other malignant ones; frequently producing great diminution of the pain of such diseases, and improving their appearance. Justamond preferred the fresh herb bruised.

Cataplasma cumini. Take of cumin seeds, one pound; bay berries, the leaves of water germander dried, Virginia snake-root, of each three ounces; cloves, one ounce; with honey equal to thrice the weight of the powder formed; of these make a cataplasm. It was formerly called Theriaca Londinensis. This is a warm and stimulating poultice, and was formerly much used as an irritating antiseptic application to gangrenous ulcers, and the like. It is now seldom ordered.

Cataplasma dauci. Carrot poultice. ℞. Radicis dauci recentis, ℔j. Bruise it in a mortar into a pulp. Some, perhaps, with reason, recommend the carrots to be first boiled. The carrot poultice is employed as an application to ulcerated cancers, scrophulous sores of an irritable kind, and various inveterate malignant ulcers.

Cataplasma fermenti. Yest cataplasm. Take of flour a pound; yest half a pint. Mix and expose to a gentle heat, until the mixture begins to rise. This is a celebrated application in cases of sloughing and mortification.

Cataplasma fuci. This is prepared by bruising a quantity of the marine plant, commonly called sea-tang, which is afterwards to be applied by way of a poultice. Its chief use is in cases of scrophula, white swellings, and glandular tumours more especially. When this vegetable cannot be obtained in its recent state, a common poultice of sea-water and oatmeal has been substituted by the late Mr. Hunter, and other surgeons of eminence.

Cataplasma lini. Linseed poultice. ℞. Farinæ lini, ℔ss. Aquæ ferventis, ℔jss. The powder is to be gradually sprinkled into the water, while they are quickly blended together with a spoon. This is the best and most convenient of all emollient poultices for common cases, and has, in a great measure, superseded the bread and milk one, so much in use formerly.

Cataplasma plumbi acetatis. ℞. Liquoris plumbi acetatis, ℥j. Aquæ distill. ℔j. Micæ panis. q. s. Misce. Practitioners, who place much confidence in the virtues of lead, often use this poultice in cases of inflammation.

Cataplasma sinapeos. See *Cataplasma sinapis.*

Cataplasma sinapis. Mustard cataplasm. Take of mustard seed, linseed, of each powdered half a pound; boiling vinegar, as much as is sufficient. Mix until it acquires the consistence of a cataplasm.

CATAPLE'XIS. (From *κατα*, and *πγησσω*, to strike.) Any sudden stupefaction, or deprivation of sensation, in any of the members, or organs.

Catapo'sis. (From *καταπινω*, to swallow down.) According to Aretæus, it signifies the instruments of deglutition.

Catapo'tium. (*Καταποτιον*; from *καταπινω*, to swallow down.) A pill.

CATAPSY'XIS. (From *ψυχω*, to refrigerate.) A coldness, or chillness, without shivering, either universal, or of some particular part.

CATAPTO'SIS. (From *καταπιπτω*, to fall down.) A falling down. 1. Such as happens in apoplexy.

2. The falling down of a limb from palsy.

CATAPU'TIA. (From *καταπυθω*, to have an ill savour; or from the Italian, *cacapuzza*, which has the same meaning; so named from its fœtid smell.) Spurge.

Cataputia major. See *Ricinus.*

Cataputia minor. See *Euphorbia Lathyris.*

CA'TARACTA. (From *καταρασσω*, to confound or disturb; because the sense of vision is confounded, if not destroyed.) A cataract; a disease of the eye. *Paropsis cataracta* of Good. The *Caligo lentis* of Cullen. Hippocrates calls it *λγαυκωμα*. Galen, *υποχυμα*. The Arabians, *gutta opaca*. Celsus, *suffusio*. It is a species of blindness, arising almost always from an opacity of the crystalline lens, or its capsule, preventing the rays of light passing to the optic nerve. It commonly begins with a dimness of sight; and this generally continues a considerable time before any opacity can be observed in the lens. As the disease advances, the opacity becomes sensible, and the patient imagines there are particles of dust, or motes, upon the eye, or in the air, which are called *muscæ volitantes*. This opacity gradually increases, till the person either becomes entirely blind, or can merely distinguish light from darkness. The disease commonly comes on rapidly, though sometimes its progress is slow and gradual. From a transparent state, it changes to a perfectly white, or light grey colour. In some very rare instances, a black cataract is found. The consistence also varies, being at one time hard, at another entirely dissolved. When the opaque lens is either more indurated than in the natural state, or retains a tolerable degree of firmness, the case is termed a *firm* or hard cataract. When the substance of the lens seems to be converted into a whitish or other kind of fluid, lodged in the capsule, the case is denominated a *milky* or *fluid cataract*. When the substance is of a middling consistence, neither hard nor fluid, but about as consistent as a thick jelly, or curds, the case is named a *soft* or caseous cataract. When the anterior or posterior layer of the crystalline capsule becomes opaque, after the lens itself has been removed from this little membraneous sac, by a previous operation, the affection is named a *secondary membraneous cataract*. There are many other distinctions made by authors. Cataract is seldom attended with pain; sometimes, however, every exposure to light creates uneasiness, owing probably to the inflammation at the bottom of the eye. The real cause of cataract is not yet well understood. Numbers of authors consider it as proceeding from a preternatural contraction of the vessels of the lens, arising from some external violence, though more commonly from some internal and occult cause. The cataraca is distinguished from gutta serena, by the pupils in the latter being never affected with light, and from no opacity being observed in the lens. It is distinguished from hypopyon, staphyloma, or any other disease in the fore-part of the eye, by the evident marks which these affections produce, as well as by the pain attending their beginning. But it is difficult to determine when the opacity is in the lens, or in its capsule. If the retina (which is an expansion of the optic nerve in the inside of the eye) be not diseased, vision may, in most cases, be restored, by either depressing the diseased lens, which is termed couching, or extracting it.

CATARRHEUʹMA. (From καταρρεω, to flow from.) A defluxion of humours from the air-passages.

CATARRHEʹXIS. (From καταρρηγνυω, to burst out.) A violent and copious eruption or effusion; joined with κοιλιας, it is a copious evacuation from the belly, and sometimes alone it is of the same signification. Vogel applies it to a discharge of pure blood from the intestines, such as takes place in dysentery.

CATARRHŒCUS. (From καταρρεω, to flow from.) A disease proceeding from a discharge of phlegm.

CATAʹRRHOPA. (From καταρρεω, to flow down.) Tubercles tending downward; or, as Galen states, those that have their apex on a depending part have received this appellation.

CATAʹRRHOPOS. (Καταρροπος νουσος.) A remission of the disease, or its decline, opposed to the paroxysm.

CATAʹRRHUS. (From καταρρεω, to flow down.) *Coryza.* A catarrh. An increased secretion of mucus from the membranes of the nose, fauces, and bronchia, with fever, and attended with sneezing, cough, thirst, lassitude, and want of appetite. It is a genus of disease in the class *Pyrexiæ*, and order *Profluvia* of Cullen. There are two species of catarrh, viz. *catarrhus à frigore*, which is very common, and is called a cold in the head; and *catarrhus à contagio*, the influenza, or epidemic catarrh, which sometimes seizes a whole city. Catarrh is also symptomatic of several other diseases. Hence we have the *catarrhus rubeolosus; tussis variolosa, verminosa, calculosa, phthisica, hysterica, à dentitione, gravidarum, metallicolarum,* &c.

Catarrh is seldom fatal, except in scrophulous habits, by laying the foundation of phthisis; or where it is aggravated by improper treatment, or repeated exposure to cold, into some degree of peripneumony; when there is hazard of the patient, particularly if advanced in life, being suffocated by the copious effusion of viscid matter into the air-passages. The epidemic is generally, but not invariably, more severe than the common form of the disease. The latter is usually left to subside spontaneously, which will commonly happen in a few days, by observing the antiphlogistic regimen. If there should be fixed pain of the chest, with any hardness of the pulse, a little blood may be taken from the arm, or topically, followed by a blister: the bowels must be kept regular, and diaphoretics exhibited, with demulcents and mild opiates to quiet the cough. When the disease hangs about the patient in a chronic form, gentle tonics and expectorants are required, as myrrh, squill, &c. In the epidemic catarrh more active evacuations are often required, the lungs being more seriously affected; but though these should be promptly employed, they must not be carried too far, the disease being apt to assume the typhoid character in its progress: and as the chief danger appears to be of suffocation happening from the cause above-mentioned, it is especially important to promote expectoration, first by antimonials, afterwards by squill, the inhalation of steam, &c. not neglecting to support the strength of the patient as the disease advances.

CATARRHUS A FRIGORE. The common defluxion from the head from cold.

CATARRHUS A CONTAGIO. The influenza.

CATARRHUS BELLINSULANUS. Mumps. See *Cynanche parotidæa.*

CATARRHUS SUFFOCATIVUS. The croup. See *Cynanche trachealis.*

CATARRHUS VESICÆ. A discharge of mucus from the bladder.

CATARTIʹSMUS. (From καταρτιζω, to make perfect.) According to Galen, it is a translation of a bone from a preternatural to its natural situation.

CATASAʹRCA. (From κατα, and σαρξ, flesh.) See *Anasarca.*

CATASBEʹSTIS. (From κατα, and σβεγνυμι, to extinguish.) The resolution of tumours without suppuration.

CATASCHAʹSMUS. (From κατασχαζω, to scarify.) Scarification.

CATASEIʹSIS. (From κατα, and σειω, to shake.) A concussion.

CATASPAʹSMA. (From κατασπαω, to draw backwards.) A revulsion or retraction of humours, or parts.

CATASTAʹGMOS. (From κατα, and σταζω, to distil.) The name which the Greeks, in the time of Celsus, had for distillation.

CATASTAʹLTICUS. (From καταστελλω, to restrain, or contract.) Styptic, astringent, repressing.

CATAʹSTASIS. Καταστασις. The constitution, state, or condition of any thing.

CATAʹTASIS. (From κατατεινω, to extend.) In Hippocrates it means the extension of a fractured limb, or a dislocated one, in order to replace it. Also the actual replacing it in a proper situation.

CATAʹXIS. (From καταγω, to break.) A fracture. Also a division of parts by an instrument.

CATE. See *Acacia catechu.*

CATECHOʹMENUS. (From κατεχω, to resist.) Resisting and making ineffectual the remedies which have been applied or given.

CAʹTECHU. (It is said, that, in the Japanese language, *kate* signifies a tree, and *chu* juice.) See *Acacia Catechu.*

CATEIAʹDION. (From κωτα, and εια, a blade of grass.) An instrument mentioned by Aretæus, having at the end a blade of grass, or made like a blade of grass, which was thrust into the nostrils to provoke an hæmorrhage when the head ached.

CATEʹLLUS. (Dim. of *catulus*, a whelp.) 1. A young whelp.

2. Also a chemical instrument called a cupel, which was formerly in the shape of a dog's head.

CATHÆʹRESIS. (From καθαιρω, to take away.) 1. The subtraction or taking away any part or thing from the body.

2. Sometimes it means an evacuation, and Hippocrates uses it for such.

3. A consumption of the body, as happens without manifest evacuation.

Cathære'tica. (From καθαιρω, to take away.) Medicines which consume or remove superfluous flesh.

CATHA'RMA. (From καθαιρω, to remove.) The excrements, or humours, purged off from the body.

Catha'rmus. (From καθαιρω, to remove.) 1. A purgation of the excrements, or humours.

2. A cure by incantation, or the royal touch.

Catha'rsia. (From καθαιρω, to purge.) Medicines which have a purging property.

CATHA'RSIS. (From καθαιρω, to take away.) Purgation of the excrements, or humours, either medically or naturally.

CATHA'RTIC. (*Catharticus*; from καθαιρω, to purge.) That which, taken internally, increases the number of alvine evacuations. These medicines have received many appellations: *purgantia*; *catocathartica*; *catoretica*; *catoteretica*; *dejectoria*; *alviduca*. The different articles referred to this class are divided into five orders.

1. *Stimulating cathartics*, as jalap, aloes, bitter apple, and croton oil, which are well calculated to discharge accumulations of serum, and are mostly selected for indolent and phlegmatic habits, and those who are hard to purge.

2. *Refrigerating cathartics*, as sulphate of soda, supertartrate of potassa, &c. These are better adapted for plethoric habits, and those with an inflammatory diathesis.

3. *Adstringent cathartics*, as rhubarb and damask roses, which are mostly given to those whose bowels are weak and irritable, and subject to diarrhœa.

4. *Emollient cathartics*, as manna, malva, caster oil, and olive oil, which may be given in preference to other cathartics, to infants and the very aged.

5. *Narcotic cathartics*, as tobacco, hyoscyamus, and digitalis. This order is never given but to the very strong and indolent, and to maniacal patients, as their operation is very powerful.

Murray, in his Materia Medica, considers the different cathartics under the two divisions of laxatives and purgatives; the former being mild in their operation, and merely evacuating the contents of the intestines; the latter being more powerful, and even extending their stimulant operation to the neighbouring parts. The following he enumerates among the principal laxatives;—Manna, Cassia fistula, Tamarindus indica, Ricinus communis, Sulphur, Magnesia. Under the head of purgatives, he names Cassia senna, Rheum palmatum, Convolvulus jalapa, Helleborus niger, Bryonia alba, Cucumis colocynthis, Momordica elaterium, Rhamnus catharticus, Aloe perfoliata, Convolvulus scammonia, Gambogia, Submurias hydrargyri, Sulphas magnesia, Sulphas sodæ, Sulphas potassæ, Supertartras potassæ, Tartras potassæ, Tartras potassæ, et sodæ, Phosphas sodæ, Murias sodæ, Terebinthina veneta, Nicotiana tabacum.

Cathartic Glaubers salt. See *Sodæ sulphas.*

Cathartic salt. See *Sulphas magnesiæ*, and *Sulphas sodæ.*

CATHARTINE. A substance of a reddish colour, a peculiar smell, and a bitter nauseous taste, soluble in water and alkohol, but insoluble in æther; obtained by Lassaigne and Fenuelle from the leaves of senna.

CATHE'DRA. (From καθεζομαι, to sit.) The anus, or rather, the whole of the buttocks, as being the part on which we sit.

Cathere'tica. (From καθαιρω, to remove.) Corrosives. Applications which, by corrosion, remove superfluous flesh.

CA'THETER. (*Catheter, teris.* m. Καθετηρ; from καθιημι, to thrust into.) A long and hollow tube, that is introduced by surgeons into the urinary bladder, to remove the urine, when the person is unable to pass it. Catheters are either made of silver or of the elastic gum. That for the male urethra is much longer than that for the female, and so curved, if made of silver, as to adapt itself to the urethra.

CATHETERI'SMUS. (From καθετηρ, a catheter.) The operation of introducing the catheter.

CATHI'DRYSIS. (From Καθιδρυω, to place together.) The reduction of a fracture, or operation of setting a broken bone.

Ca'thmia. A name for litharge.

Ca'thodos. (From κατα, and οδος.) A descent of humours.

Catho'lceus. (From κατα, and ολκεω, to draw over.) An oblong fillet, made to draw over and cover the whole bandage of the head.

CATHO'LICON. (From κατα, and ολικος, universal.) A universal medicine: formerly applied to a medicine, that was supposed to purge all the humours.

CATHY'PNIA. (From κατα, and υπνος, sleep.) A profound but unhealthy sleep.

Ca'tias. (From καθιημι, to place in.) An incision knife, formerly used for opening an abscess in the uterus, and for extracting a dead fœtus.

Cati'llus. See *Catellus.*

Ca'tinum alumen. A name given to potassa.

CA'TINUS. Κατανον. A crucible.

CAT-KIN. See *Amentum.*

CA'TMINT. (So called, because cats are very fond of it.) See *Nepeta.*

CATOCATHA'RTICA. (From κατω, downwards, and καθαιρω, to purge.) Medicines that operate by stool.

Ca'toche. (From κατεχω, to detain.) See *Catalepsis.*

CATOCHEI'LUM. (From κατω, beneath, and χειλος, the lip.) The lower lip.

CA'TOCHUS. (From κατεχω, to detain.) A spasmodic disease in which the body is rigidly held in an upright posture.

Catomi'smus. (From κατω, below, and ωμος, the shoulder.) By this word, P. Ægineta expresses a method of reducing a luxated shoulder, by raising the patient over the shoulder of a strong man, that by the weight of the body, the dislocation may be reduced.

CATO'PSIS. (From κατοπτομαι, to see clearly.) An acute and quick perception. The acuteness of the faculties which accompanies the latter stages of consumption.

Catophyllum inophyllum. *Calaba.* The Indian mastich tree. A native of America, where the whole plant is considered as a resolvent and anodyne.

Cato'pter. (From κατα, and οπτομαι, to see; by metaphor, a probe.) An instrument called a speculum ani.

Catorchi'tes. (From κατα, and ορχις, the orchis.) A wine in which the orchis root has been infused.

Catore'tica. (From κατω, downwards, and ρεω, to flow.) *Catoteretica*; *Catoterica.* Medicines which purge by stool.

Catotere'tica. See *Catoretica.*

CATOTICA. (*Catoticus*; from κατω, below; whence κατωτερος, and κατωτατος, *inferior*, and *infernus.*) The name of an order of the class *Eccritica*, in Good's Nosology; diseases affecting internal surfaces; defined, pravity of the fluids, or emunctories that open into the internal surfaces of organs. It embraces *hydropis*, *emphysema*, *paruria*, and *lithia*.

Cats-eye. A mineral, much valued as a precious stone, brought from Ceylon,

Catulo′tica. (From κατουλοω, to cicatrize.) Medicines that cicatrize wounds.

Catutri′pali. A name of the *piper longum*.

Catulus. See *Amentum.*

CAU′CALIS. (From καυκιον, a cup; or from δαυκαλις, the daucus.) 1. The name of a family, or genus of plants. Class, *Pentandria*; Order, *Monogynia*.

2. Bastard parsley; so named from the shape of its flower.

3. The wild carrot.

CAUCALOI′DES. (From *caucalis*, and ειδος, a likeness; from its likeness to the flower of the caucalis.) Like unto the caucalus. The patella is sometimes so called.

CAU′DA. (From *cado*, to fall; because it hangs or falls down behind.) A tail.

1. The tail of animals.

2. A name formerly given to the os coccygis, that being in tailed animals the beginning of the tail.

3. A fleshy substance, projecting from the lips of the vagina, and resembling a tail, according to Aëtius.

4. Many herbs are called cauda, with the affixed name of some animal, the tail of which the herb is supposed to be like; as *cauda equina*, horse-tail; *cauda muris*, mouse-tail; and in many other instances.

Cauda equina. 1. The spinal marrow, at its termination about the second lumbar vertebra, gives off a large number of nerves, which, when unravelled, resemble the horse's tail; hence the name. See *Medulla spinalis.*

2. See *Hippuris vulgaris.*

Cauda seminis. The tail, or elongated generally feathery appendage to a seed, formed of the permanent style. It is simple, in *Geranium zonale*; hairy, in *Clematis* and *Pulsatilla*; and geniculate in *Tormentilla*.

Cauda′tio. (From *cauda*, a tail.) An elongation of the clitoris.

CAUDATUS. (From *cauda*, a tail.) Tailed: applied to seeds which have a tail-like appendage; as those of the *Clematis vitalba*, and *Anemone sulphurea*.

CAUDEX. (*Caudex*, *icis*. m.) The body of the root of a plant. See *Radix*.

CAUL. 1. The English name for the omentum. See *Omentum*.

2. The amnion, which is sometimes torn by the child's head, passing from the uterus, and comes away with it wholly separated from the placenta.

Caule′don. (From καυλος, a stalk.) A transverse fracture, when the bone is broken, like the stump of a tree.

CAU′LIFLOWER. A species of brassica, the flower of which is cut before the fructification expands. The observations which have been made concerning cabbages are applicable here. Cauliflower is, however, a far more delicious vegetable. See *Brassica capitata.*

CAULINUS. Cauline. Belonging to the stem. Leaves and peduncles are so called, which grow on, or come immediately from, the stem.

CAU′LIS. (*Caulis*, *is*. m. Καυλος; from *kalab*, a Chaldean word.) The stalk or stem of herbaceous plants. The characters of the stalk are, that it is rarely ligneous, and lives but one or two years in the natural state of the plant.

A plant is said to be

Caulescent, when furnished with a stem.

Acauline, when without a stem; as in Carlina acaulis.

From its *duration*, the stem is distinguished into

1. *Caulis herbaceus*, which perishes every year; as Melissa officinalis.

2. *Caulis suffruticosus*, which perishes halfway down every year; as Cheiranthus incanus.

3. *Caulis fruticosus*, shrubby, having many stems, which do not perish in the winter; as Melissa fruticosa.

4. *Caulis arboreus*; as the trunk of trees.

From the substance, it is distinguished into

5. *Caulis fistulosus*, hollow internally; as in Anethum graveolens, and Allium fistulosum.

6. *Caulis loculamentosus*, hollow and divided into cells; as in Angelica, Archangelica, and Phellandrum aquaticum.

7. *Caulis inanis*, or *medullosus*, empty or pithy; as in Sambucus nigra.

8. *Caulis solidus*, solid; as in Mentha and Melissa.

9. *Caulis ligneus*, woody; as Prunus spinosa.

10. *Caulis carnosus*, fleshy; as, in Sedum arboreum, and Stapelia hirsuta.

11. *Caulis pulposus*, pulpy; as in Mesembryanthemum crystallinum.

12. *Caulis fibrosus*, separable into long fibres; as Cocos nucifera.

13. *Caulis succosus*, full of a juice; as in the Euphorbias, and Chelidonium majus.

From the difference of the surface, the *caulis* is said to be

14. *Glaber*, or *lævis*, smooth, without any hairiness, or roughness, or inequality; as Lepedium latifolium.

16. *Suberosus*, corky; as, Passiflora suberosa, and Quercus suber.

15. *Scaber*; or *asper*, when it has hard inequalities as in Galium aperine, and Lithospermum arvense.

17. *Rimosus*, cracky; as in Ulmus campestris.

18. *Tuberculatus*, with rough nobs; as in Cissus tuerculatab.

19 *Tunicatus*, the cuticle peeling off spontaneously in large portions; as in Betula alba, and some of the Spiræas.

20. *Striatus*, having superficial longitudinal lines; as in Chærophyllum sylvestre, Aster sibiricus, and Daphne mezereon.

21. *Sulcatus*, furrowed, fluted, when longitudinally indented with long and deep hollows; as in Celosia coccynea, Selinum carvifolia, Pimpinella sanguisarba, Doronicum pardalianches.

22. *Perfoliatus*, perfoliate; as in Bupleurum perfoliatum.

The *figure* affords the following distinctions:

23. *Caulis teres*, or *cylindricus*, round, without angles; as Sinapis arvensis.

24. *Semiteres*, half-rounded, flat on one side; as Hyacinthus orientalis, Allium descendens.

25. *Caulis compressus*, which implies that two sides of the stem are flat, and approach each other; as in Poa compressa, Lathyrus latifolius, Pancratium declinatum.

26. *Caulis anceps*, two-edged; as Iris graminea, Hypericum androsemum.

27. *Caulis angulatus*, presenting several acute angles in its circumference.

a. *Triangulatus*, three-cornered; as in Cactus triangularis.

b. *Quadrangulatus*, four-cornered; as Cactus teragonus.

c. *Quinqueangulatus;* as in Cactus pentagonus.

d. *Sexangulatus*, six-cornered; as Cactus hexagonus.

e. *Multangulatus*, many-cornered; as Cactus cereus.

28. *Caulis obtusangulatus*, obtuse-angled; as in Scrophularia nodosa.

29. *Caulis acutangulatus*, acute-angled; as in Scrophularia aquatica.

30. *Caulis triquetrus*, three-sided, when there are three flat sides, forming acute angles; as Hedysarum triquetrum, Viola mirabilis, Carex acuta.

31. *Caulis tetraquetrus*, four-sided; as in Hypericum quadrangulare, Monarda fistulosa, Mentha officinalis.

32. *Caulis membranaceus*, leaf-like; as in Cactus phyllanthus.

33. *Caulis alatus*, when the edges or angles expand into leaf-like borders; as in Onopordium acanthium, and Lathyrus latifolius.

34. *Caulis articulatus*, jointed; as Cactus flagelliformis and Lathyrus sylvestris.

35. *Caulis nodosus*, knotty, divided at intervals by swellings; as in Scandix nodosa, Geranium nodosum.

36. *Caulis enodus*, without knot.

From the directions, a stem is called

37. *Rectus*, erect, when it ascends almost perpendicularly; as the firs, Chenopodium scoparium, &c.

38. *Strictus*, straight, perfectly perpendicular; as Alcea rosea.

39. *Obliquus*, oblique; as the Solidago mexicana.

40. *Adscendens*, ascending, when its lower portion forms a curve, the convexity of which is towards the earth, or rests upon it, and the summit rises; as exemplified in many grasses, Trifolium pratense, Hedysarum onobrychis.

41. *Descendens*, or *Declinatus*, the reverse of the former, forming an arch, towards the ground; as in Pancratium declinatum, Ficus carica.

42. *Nutans*, or *cernuus*, nodding, when bent towards the summit; as Polygonatum multiflora.

43. *Procumbens*, or *Prostatus*, lying on the earth; as Veronica officinalis.

44. *Decumbens*, rising a little, and returning to the earth; as Thymus serphyllum.

45. *Repens*, creeping and sending radicles into the ground; as Trifolium repens, Gnaphalium repens.

46. *Flexuosus*, zigzag; as in Celastrus buxifolius, and Solidago flexicaulis.

47. *Radicaus*, sending fibres which take root in the earth; as Ficus indica.

48. *Sarmentosus*, trailing, or sending off a runner, which fixes on neighbouring bodies; as the Hedera helix.

49. *Stoloniferus*, sending off radicating stolos; as Agrostis stolonifera, and Fragaria vesca.

50. *Scandens*, climbing, furnished with tendrils; as solanum dulcamara, Cobœa scandens.

51. *Volubilis*, twining, winding itself spirally round any other plant or body.

a. *Dextrorsum*, when from right to left; as Phaseolus multiflorus, and Convolvulus.

b. *Sinistrorsum*, in the opposite direction, or following the apparent motion of the sun; as the Lonicera pericleminum, and Humulus lupulus.

52. *Laxus*, bent by the lightest wind; as Secale sereale, and Juncus bufonius.

53. *Rigidus*, breaking when lightly bent; as Boerhaavia scandens.

When *clothed* with any kind of appendage, the stem is designated by a term expressive of this, thus,

54. *Caulis foliosus*, when leafy; as Melissa officinalis.

55. *Caulis aphyllus*, when without leaves; as Asphodelus fistulosus.

56. *Caulis squamosus*, scaly; as the Orobanche major.

57. *Caulis stipulatus*, when furnished with stipulæ; as Cystus helianthemum, and Geranium terebinthinaceum.

58. *Caulis imbricatus*, tiled or covered with little leaves or scales; as Crassula imbricata, Aloe viscosa.

59. *Caulis vaginatus*, sheathed, embraced by the base of a leaf as by a sheath; as Canna indica, Arundo donax.

60. *Caulis bulbiferus*, bulb-bearing, when studded with bulbs in the axilla of the leaves; as Lilium bulbiferum.

61. *Caulis nudus*, naked, without leaf, scale, or other covering; as Cuscuta europea.

From its mode of *branching*, into

62. *Caulis simplex*, having few branches; as Campanula perfoliata, Verbascum thapsus.

63. *Caulis simplicissimus*, without branches; as Orobanche americana and major, Campanula barbata.

64. *Caulis prolifer*, giving off branches only from the tops of the former; as the Dracena draco.

65. *Caulis dichotomus*, forked, always divided into pairs; as in Horanthus europæus and Valeriana locusta.

66. *Caulis ramosus*, branched; as Rosmarinus officinalis.

67. *Caulis ramossissimus*, having many branches; as Chenopodium scoparia, Ulmus, Grossularia, &c.

68. *Caulis paniculatus*, paniculate; as in Crambe tataria.

From the *pubescence* and *armature*, or defences, into

69. *Caulis spinosus*, when furnished with sharp spines; as Prunus spinosa, and Mespilus oxyacantha.

70. *Caulis aculeatus*, prickly, when covered with sharp-pointed bodies; as Rosa centifolia and eleganterea.

71. *Caulis cetaceus*, bristly, when the armature consists of brushes of minute bristles; as Cactus flagelliformis.

72. *Caulis ramentaceus* ramentaceous; as in Erica ramentacea.

73. *Caulis pilosus*, hairy, the pubescence consisting of long hairs; as Hieraccum pilocella, Salvia pratensis.

74. *Caulis muricatus*, or *hispidus*, when the hairs are stiff or bristly; as Borago officinalis, and Echium vulgare.

75. *Caulis tomentosus*, downy, soft to the touch, like down; as Verbascum thapsus, and Geranium rotundifolium.

76. *Caulis villosus*, shaggy; as Stachys germanica, and Veronica villosa.

77. *Caulis lanatus*, woolly, when the hairs are long and matted: as in Stachys lanata, and Ballota lanata.

78. *Caulis sericus*, silky, when the hairs are shining and silky.

Instead of pubescence, the covering is in some instances either a dry powdery, or a moist, excretion; and hence, the stem is demoninated either

79. *Incanus*, or *pruinosus*, when covered with a fine white dust; as the Atriplex portulacoidis.

80. *Farinosus*, mealy; as the Primula farinosa.

81. *Glaucus*, of a sea-green colour; as Ricinus officinalis.

82. *Viscidus*, viscid, covered with a resinous exudation; as Siline viscosa.

83. *Glutinosus*, glutinous, when the exudation is adhesive and soluble in water; as in Primula glutinosa.

The primary division of a stem is into *lateral stems* or *branches.* These are variously denominated,

From their *situation*, into

84. *Opposite*, when one branch stands on the opposite side of the stem to another, and their bases are nearly on the same plane; as in Mentha arvensis.

85. *Alternate*, one opposite to another, alternately; as Althæa officinalis.

86. *Verticillated*, when more than two proceed from a centre, like the spokes of a wheel; as Pinus abies.

87. *Scattered*, when given off from the stem in any indeterminate manner.

From their *direction*, the branches, or rami, are termed,

88. *Patentes*, spreading, when the angle formed by the branch and the upper part of the stem is obtuse; as in Galium mollugo, and Cestus italicus.

89. *Patentissimi*, proceeding at a right angle from the stem, or horizontally; as Ammania ramosior, and Asparagus officinalis.

90. *Brachiati*, brachiate, spread in four directions, crossing each other alternately in pairs; as Syringa vulgaris, and Panisteria brachiata.

91. *Deflexi*, bending downward from the stem, in an arched or curved direction; as Pinus larix.

92. *Reflexi*, hanging almost perpendicularly from the stem; as Salix babylonica.

93. *Retroflexi*, turned backward; as in Solanum dulcamara.

94. *Introflexi* bent inward, when the tops bend towards the stem; as Populus dilatata.

95. *Fastigiati*, when the tops of the branches, from whatever part of the stem they spring, rise nearly to the same height; as Chrysanthemum corymbosum, and Dianthus barbatus.

96. *Virgati*, weak and long; as Salix viminalis.

97. *Appressi*, approximated, when nearly parallel and close to the stem; as Genista tinctoria.

98. *Fulcrate*, supported, when they project nearly horizontally, and give out root-like shoots from the under side, which, extending until they reach the ground, take root, and serve as props to the branches; as in the banyan tree, or Ficus religiosus.

CAULIS FLORIDA. Cauliflower.

CAULO'DES. (From καυλος, a stem.) The white or green cabbage.

CAULO'TOM. (From καυλος, a stem; because it grows upon a stalk.) A name given to the beet.

CAU'MA. (Καυμα, heat; from καιω, to burn.) The heat of the body in a fever.

2. The heat of the atmosphere in a fever.

3. The name given by Good and Young, to an inflammatory fever.

CAU'NGA. A name of the areca.

CAU'SIS. (From καιω, to burn.) A burn; or rather, the act of combustion, or burning.

CAUSO'DES. (From καιω, to burn.) A term applied by Celsus to a burning fever.

CAUSO'MA. (From καιω, to burn.) An ardent or burning heat and inflammation. A term used by Hippocrates.

CAUSTIC. See *Causticum.*

Caustic alkali. The pure alkalies are so called. See *Alkali.*

Caustic barley. See *Cevadilla.*

Caustic lunar. See *Argenti nitras.*

Caustic volatile alkali. See *Ammonia.*

CAU'STICUM. (From καιω, to burn; because it always produces a burning sensation.) A caustic. A substance which has so strong a tendency to combine with organised substances, as to destroy their texture. See *Escharotic.*

CAUSTICUM AMERICANUM. The cevadilla. See *Veratrum sabadilla.*

CAUSTICUM ANTIMONIALE. Muriate of antimony.

CAUSTICUM ARSENICALE. See *Arsenical caustic.*

CAUSTICUM COMMMUNE FORTIUS. See *Potassa cum calce.*

CAUSTICUM LUNARE. See *Argenti nitras.*

CAU'SUS. (From καιω, to burn.) A highly ardent fever. According to Hippoorates, a fiery heat, insatiable thirst, a rough and black tongue, complexion yellowish, and the saliva bilious, are its peculiar characteristics. Others also are particular in describing it; but, whether ancients or moderns, from what they relate, this fever is no other than a continued *ardent fever* in a bilious constitution. In it the heat of the body is intense; the breath is particularly fiery; the extremities are cold; the pulse is frequent and small; the heat is more violent internally than externally, and the whole soon ends in recovery or death.

CAUTERY. (*Cauterium*, from καιω, to burn.) Cauteries were divided, by the ancients, into *actual* and *potential;* but the term is now given only to the red-hot iron, or *actual cautery.* This was formerly the only means of preventing hæmorrages from divided arteries, till the invention of the ligature. It was also used in diseases, with the same view as we employ a blister. *Potential* cautery was the name by which kali purum, or potassa, was distinguished in former dispensatories. Surgeons of the present day understand, by this term, any caustic application.

CA'VA. See *Cavus.*

CAVE'RNA. (From *cavus*, hollow.) A cavern. The pudendum muliebre.

CAVIARE. *Caviarium.* A food made of the hard roes of sturgeon, formed into a soft mass, or into cakes, and much esteemed by the Russians.

CAVI'CULA. (Diminutive of *cavilla.*) See *Cavilla.*

CAVI'LLA. (From *cavus.*) The ankle, or hollow of the foot.

CA'VITY. (*Cavitas*, from *cavus*, hollow.) 1. Any cavity, or hollowness.

2. The auricle of the heart was formerly called *cavitas innominata*, the hollow without a name.

CAVUS. Hollow. 1. The name of a vein, *vena cava.* See *Veins.*

2. Applied to the roots of plants; as that of the *Fumaria cava.*

CAWK. A term by which the miners distinguish the opaque specimens of sulphate of barytes.

Cayenne pepper. See *Capsicum.*

CAZABI. See *Jatropha.*

CEANO'THUS. (From κεανωϑος, quia κεει ανωϑεν, because it pricks at the extreme part.)

A genus of plants in the Linnæan system. Class, *Pentandria*; Order, *Monogynia.*

Ceanothus americanus. *Celastrus*; *Celastus.* Some noted Indians depend more on this plant, than on the lobelia, for the cure of syphilis, and use it in the same manner as lobelia.

Cea'sma. (From κεω, to split, or divide.) *Ceasmus.* A fissure, or fragment.

Ce'ber. (Arabian.) The Lignum aloes. Also the capparis.

Cebipi'ra. (Indian.) A tree which grows in Brazil, decoctions of the bark of which are used in baths and fomentations, to relieve pains in the limbs, and cutaneous diseases.

CE'DAR. See *Pinus cedrus.*

Ce'dma. (From κεδαω, to disperse.) A defluxion, or rheumatic affection, of the parts about the hips.

Ce'drinum lignum. See *Pinus cedrus.*

Cedri'tes. (From κεδρος, the cedar-tree.) Wine in which the resin which distils from the cedar-tree has been steeped.

CE'DRIUM. 1. Cedar, or cedar-tree. 2. Common tar, in old writings.

Cedrome'la. The fruit of the citron-tree.

Cedrone'lla. Turkey baum.

Cedro'stis. (From κεδρος, the cedar-tree.) A name of the white bryony, which smells like the cedar. See *Bryonia alba.*

CE'DRUS. (From *Kedron*, a valley where this tree grows abundantly.) See *Pinus cedrus.*

Cedrus americana. The arbor vitæ.

Cedrus baccifera. The savine.

Cei'ria. (From κειρω, to abrade.) The tapeworm; so called from its excoriating and abrading the intestines.

CE'LANDINE. See *Chelidonium majus.*

Cela'strus. (From κελα, a dart, which it represents.) See *Ceanothus americanus.*

Cela'stus. See *Ceanothus americanus.*

CE'LE. (From κηλη.) A tumour caused by the protusion of any soft part. Hence the compound terms *hydrocele, bubonocele*, &c.

CE'LERY. The English name for a variety of the apium graveolens.

CELESTINE. So called from its occasional delicate blue colour. A native sulphate of strontites. See *Heavy spar.*

Ce'lis. (From καιω, to burn.) A spot or blemish upon the skin, particularly that which is occasioned by a burn.

Ce'lla turcica. See *Sella turcica.*

CE'LLULA. (Diminutive of *cella*, a cell.) A little cell, or cavity.

Cellulæ mastoideæ. See *Temporal bones.*

CE'LLULAR. *Cellularis.* Having little cells.

Cellular membrane. *Membrana cellulosa*; *Tela cellulosa*; *Panniculus adiposus*; *Membrana adiposa, pinguedinosa* et *reticularis.* Cellular tissue. The cellular tissue of the body, composed of laminæ and fibres variously joined together, which is the connecting medium of every part of the body. It is by means of the communication of the cells of this membrane, that the butchers blow up their veal. The cellular membrane is, by some anatomists, distinguished into the reticular and adipose membrane. The former is evidently dispersed throughout the whole body, except the substance of the brain. It makes a bed for the other solids of the body, covers them all, and unites them one to another. The adipose membrane consists of the reticular substance, and a particular apparatus for the secretion of oil, and is mostly found immediately under the skin of many parts, and about the kidneys.

CELOTO'MIA. (From κηλη, hernia, and τεμνω, to cut.) The operation for hernia.

Ce'lsa. A term of Paracelsus, to signify what is called the live blood in a particular part.

CE'LSUS, Aurelius Cornelius. It is commonly supposed, that this esteemed ancient author was a Roman, of the Cornelian family, born towards the end of the reign of Augustus, and still living in the time of Caligula. But these points are not established upon certain testimony, and it is even disputed whether he practised medicine; though his perfect acquaintance with the doctrines of his predecessors, his accurate descriptions of diseases, and his judicious rules of treatment, appear to leave little room for doubt on that head. At any rate, his eight books, "De Medicina," have gained him deserved celebrity in modern times, containing a large fund of valuable information; detailed in remarkably elegant and concise language. In surgery particularly he has been greatly admired, for the methods of practice laid down, and for describing several operations as they are still performed. There have been numerous editions of his work, and translations of it into the several modern languages.

CEMENT. Chemists call by this name whatever they employ to unite or cement things together; as lutes, glues, solders of every kind.

CEMENTATION. A chemical process, which consists in surrounding a body in the solid state with the powder of some other bodies, and exposing the whole for a time in a closed vessel, to a degree of heat not sufficient to fuse the contents. Thus iron is converted into steel by cementation with charcoal; green bottle glass is converted into porcelain by cementation with sand, &c.

Ceme'nterium. A crucible.

Ce'nchramis. (From κεγχρος, millet.) A grain or seed of the fig.

Ce'nchrius. A species of herpes that resembles κεγχρος, or millet.

CENEANGEI'A. (From κενος, empty, and αγγος, a vessel.) A deficiency of blood, or other fluids in the vessels; so that they have not their proper quantity.

Ceni'glam. *Ceniplam*; *Cenigotam*; *Cenipolam.* An instrument anciently used for opening the head in epilepsies.

Ceniote'mium. A purging remedy, formerly of use in the venereal disease, supposed to be mercurial.

CENO'SIS. (From κενος, empty.) Evacuation. It imports a general evacuation. *Catharsis* was applied to the *evacuation* of a particular humour, which offends with respect to quality.

CENOTICA. (*Cenoticus*; from κενωςις, *evacuatio, exinanitio*, emptiness.) The name of an order in the class *genetica* of Good's Nosology: diseases affecting the fluids, and embracing *paramenia, leucorrhœa, blennorrhœa, spermorrhœa*, and *galectea.*

CENTAU'REA. (So called from *Chiron*, the centaur, who is said to have employed one of its species to cure himself of a wound accidentally received, by letting one of the arrows of Hercules fall upon his foot.) The name of a genus of plants in the Linnæan system, of the Order, *Polygamia frustanea*; Class, *Syngenesia.*

Centaurea behen. The systematic name of the officinal *behen album*; *Jacea orientalis patula*; *Raphonticoides lutea.* The true white behen of the ancients. The root possesses astringent virtues.

Centaurea benedicta. The systematic

name of the blessed or holy thistle. *Carduus benedictus; Cnicus sylvestris; Centaurea benedicta—calycibus duplicato-spinosis lanatis involucratis, foliis semi-decurrentibus denticulato-spinosis* of Linnæus. This exotic plant, a native of Spain, and some of the Archipelago islands, obtained the name of Benedictus, from its being supposed to possess extraordinary medicinal virtues. In loss of appetite, where the stomach was injured by irregularities, its good effects have been frequently experienced. It is a powerful bitter tonic and adstringent. Bergius considers it as antacid, corroborant, stomachic, sudorific, diuretic, and eccoprotic. Chamomile flowers are now generally substituted for the *carduus benedictus*, and are thought to be of at least equal value.

Centaurea calcitrapa. The systematic name of the common star-thistle. Star-knapweed. *Calcitrapa; Carduus stellatus; Jacea ramosissima, stellata, rupina.* The plant thus called in the pharmacopœias, is the *Centaurea—calycibus subduplicato-spinosis, sessilibus; foliis pinnatifidis, linearibus dentatis; caule piloso*, of Linnæus, every part of which is bitter. The juice, or extract, or infusion, is said to cure intermittents; and the bark of the root, and the seeds, have been recommended in nephritic disorders, and in suppression of urine. It scarcely differs, in its effects, from other bitters, and is now little used.

Centaurea centaurium. *Rhaponticum vulgare; Centaurium magnum; Centaurium majus.* Greater centaury. The root of this plant was formerly used as an aperient, and corroborant in alvine fluxes. It is now totally discarded from the Materia Medica of this country.

Centaurea cyanus. The systematic name of the blue-bottle, or corn-flower plant. *Cyani; Cyanus.* The flowers of this plant, *Centaurea—calycibus serratis; foliis linearibus, integerrimis, infimis dentatis*, of Linnæus, were formerly in frequent use; but their antiphlogistic, antispasmodic, cordial, aperient, diuretic, and other properties, are now, with great propriety, forgotten.

Centaurea solstitialis. *Calcitrapa officinalis; Carduus stellatus luteus; Carduus solstitialis; Jacea stellata; Jacea lutea capite spinoso minori; Leucanthe veterum.* St. Barnaby's thistle. It is commended as an anticteric, anti-cachectic, and lithontriptic, but is in reality, only a weak tonic.

Centaurioi'des. The gratiola.

CENTAU'RIUM. (From κενταυρος, a centaur; so called because it was feigned that Chiron cured Hercules's foot, which he had wounded with a poisonous arrow, with it.) Centaury. See *Chironia centaurium.*

Centaurium magnum. See *Centaurea, Centaurium.*

Centaurium majus. See *Centaurea, Centaurium.*

Centaurium minus. See *Chironia, centaurium.*

CENTAU'RY. See *Chironia.*

Centimo'rbia. (From *centum*, a hundred, and *morbus*, a disease.) The *Lysimachia nummularia*, or moneywort, was so named, from its supposed efficacy in the cure of a multitude of disorders.

Centino'dia. See *Centum nodia.*

CENTI'PES. (From *centum*, a hundred, and *pes*, a foot.) The woodlouse, so named from the multitude of its feet.

Centra'tio. (From *centrum*, a centre.) The concentration and affinity of certain substances to each other. Paracelsus expresses by it the degenerating of a saline principle, and contracting a corrosive and exulcerating quality. Hence *Centrum salis* is said to be the principle and cause of ulcers.

Ce'ntrium. (From κεντεω, to prick.) A plaster recommended by Galen against stitches and pains in the side.

CE'NTRUM. (From κεντεω, to point or prick.) 1. The middle point of a circle.

2. In chemistry it is the residence or foundation of matter.

3. In medicine, it is the point in which its virtue resides.

4. In anatomy, the middle point of some parts is so named, as *centrum nerveum*, the middle or tendinous part of the diaphragm.

Centrum nerveum. The centre of the diaphragm. See *diaphragm.*

Centrum ovale. When the two hemispheres of the brain are removed on a line with a level of the *corpus callosum*, the internal medullary part presents a somewhat oval centre, which is called *centrum ovale.* Vieussenius supposed all the medullary fibres met at this place.

Centrum tendinosum. The tendinous centre of the diaphragm. See *Diaphragm.*

CENTUMNO'DIA. (From *centum*, a hundred, and *nodus*, a knot; so called from its many knots or joints.) *Centinodia.* Common knotgrass. See *Polygonum aviculare.*

Centu'nculus. Bastard pimpernel.

CE'PA. (From κηπος, a wool-card, from the likeness of its roots.) The onion. See *Allium cepa.*

Cepæ'a. A species of onion.

CEPHALÆ'A. (From κεφαλη, the head.) 1. The flesh of the head which covers the skull.

2. A headache. Dr. Good makes this a genus of disease in his Order, *Systatica*; Class, *Neurotica.* It has five species, *Cephalæa, graverus, intensa, hemicrania, pulsatilis, nauscosa.*

CEPHA'LALGIA. (From κεφαλη, the head, and αλγος, pain.) *Cephalæa.* The headache. It is symptomatic of very many diseases, but is rarely an original disease itself. When mild it is called cephalalgia; when inveterate, cephalæa. When one side of the head only is affected, it takes the names of *hemicrania, migrana, hemipagia*, and *megrim*; in one of the temples only, *crotaphos*; and that which is fixed to a point, generally in the crown of the head, if distinguished by the name of *clavus.*

Cephala'rtica. (From κεφαλη, the head, and αρτιζω, to make pure.) Medicines which purge the head.

CE'PHALE. Κεφαλη. The head.

CEPHALIC. (From κεφαλη, the head.) Pertaining to the head. 1. A variety of external and internal medicines are so called, as being adapted for the cure of disorders of the head. Of this class are the snuffs, which produce a discharge from the mucous membrane of the nose, &c.

2. Nerves, arteries, veins, muscles, &c. are so called which are situated on the head.

3. The name of a vein of the arm, which it was supposed went to the head.

Cephalic vein. (*Vena cephalica*; so called because the head was supposed to be relieved by opening it.) The anterior or outermost vein of the arm that receives the cephalic of the thumb.

Cephalicus pulvis. A powder prepared from asarum.

CEPHALI'TIS. (From κεφαλη the head.) Inflammation of the head. *Empresma cephalitis* of Good. See *Phrenitis.*

CEPHALO. This term is joined to others to denote the connexion of the muscle, artery, nerve, &c. to the head.

CEPHALONO'SUS. (From κεφαλη, the head, and νοσος, a disease.) Any disease of the head. Applied to the febris hungarica, in which the head is principally affected.

Cephalo-pharyngeus. (From κεφαλη, the head, and φαρυγξ, the throat.) A muscle of the pharynx. See *Constrictor pharyngis inferior.*

CEPHALOPONIA. (From κεφαλη, the head, and ϖονος, pain.) Headache.

Cepi'ni. Vinegar.

Cepula. Large myrobalans.

CE'RA. Wax. Bees' wax. A solid concrete substance, collected from vegetables by bees, and extracted from their combs after the honey is got out, by heating and pressing them.

It was long considered as a resin, from some properties common to it with resins. Like them, it furnishes an oil and an acid by distillation, and is soluble in all oils; but in several respects it differs sensibly from resins. Like these, wax has not a strong aromatic taste and smell, but a very weak smell, and when pure, no taste. With the heat of boiling water, no principles are distilled from it; whereas, with that heat, some essential oil, or at least a spiritus rector, is obtained from every resin. Farther, wax is less soluble in alkohol. If wax be distilled with a heat greater than that of boiling water, it may be decomposed, but not so easily as resins can. By this distillation, a small quantity of water is first separated from the wax, and then some very volatile and very penetrating acid, accompanied with a small quantity of a very fluid and very odoriferous oil. As the distillation advances, the acid becomes more and more strong, and the oil more and more thick, till its consistence is such that it becomes solid in the receiver, and is then called butter of wax. When the distillation is finished, nothing remains but a small quantity of coal, which is almost incombustible.

Wax cannot be kindled, unless it is previously heated and reduced into vapours; in which respect it resembles fat oils. The oil of butter of wax may by repeated distillations be attenuated and rendered more and more fluid, because some portion of acid is thereby separated from these substances; which effect is similar to what happens in the distillation of other oils and oily concretes: but this remarkable effect attends the repeated distillation of oil and butter of wax, that they become more and more soluble in alkohol; and that they never acquire greater consistence by evaporation of their more fluid parts. Boerhaave kept butter of wax in a glass vessel open, or carelessly closed, during twenty years, without acquiring a more solid consistence. It may be remarked, that wax, its butter, and its oil, differ entirely from essential oils and resins in all the above-mentioned properties, and that in all these they perfectly resemble sweet oils. Hence Maquer concludes, that wax resembles resins only in being an oil rendered concrete by an acid; but that it differs essentially from these in the kind of the oil, which in resins is of the nature of essential oils, while in wax and in other analogous oily concretions (as butter of milk, butter of cocoa, fat of animals, spermaceti, and myrtle-wax,) it is of the nature of mild unctuous oils, that are not aromatic, and not volatile, and are obtained from vegetables by expression. It seems probable, that the acidifying principle, or oxygen, and not an actual acid, may be the leading cause of the solidity, or low fusibility of wax.

In the state in which it is obtained from the combs, it is called yellow wax, *cera flava*; and this, when new, is of a lively yellow colour, somewhat tough, yet easy to break: by age, it loses its fine colour, and becomes harder and more brittle. Yellow wax, after being reduced into thin cakes, and bleached by a long exposure to the sun and open air, is again melted, and formed into round cakes, called virgin wax, or white wax, *cera alba.* The chief medicinal use of wax, is in plasters, unguents, and other like external applications, partly for giving the requisite consistence to other ingredients, and partly on account of its own emollient quality.

Cera alba. See *Cera.*

Cera dicardo. The carduus pinea.

Cera flava. Yellow wax. See *Cera.*

Ceræ'æ. (From κερας, a horn.) So Rufus Ephesius calls the cornua or appendages of the uterus.

Cerani'tes. (From κεραννυμι, to temper together.) A name formerly applied to a pastil, or troch, by Galen.

Ce'ras. (Κερας, a horn.) A wild sort of parsnip is so named from its shape.

CE'RASA. (Κερασος, the cherry-tree; from Κερασουντη, a town in Pontus, whence Lucullus first brought them to Rome: or from κηρ, the heart; from the fruit having a resemblance to it in shape and colour.) The cherry. See *Prunus.*

Cerasa nigra. See *Prunus avium.*

Cerasa rubra. See *Prunus cerasus.*

Cerasia'tum. (From *cerasus*, a cherry; so called because cherries are an ingredient.) A purging medicine in Libavius.

CE'RASIN. The name given by Dr. John of Berlin to those gummy substances which swell in cold water, but do not readily dissolve in it. Cerasin is soluble in boiling water, but separates in a jelly when the water cools. Water acidulated with sulphuric, nitric, or muriatic acid, by the aid of a gentle heat, forms a permanent solution of cerasin. Gum tragacanth is the best example of this species of vegetable product.

Cera'sius. (From *cerasus*, a cherry.) *Crasios.* The name of two ointments in Mesue.

Cera'sma. (From κεραννυμι, to mix.) A mixture of cold and warm water, when the warm is poured into the cold.

CE'RASUS. The cherry and cherry-tree. See *Prunus cerasus.*

CE'RATE. *Ceratum.* A composition of wax, oil, or lard, with or without other ingredients. The obsolete synonyms are, *cerelæum, ceroma, ceronium, cerotum, ceratomalagma.* Cerates take their name from the wax which enters into their composition, and to which they owe their consistence, which is intermediate between that of plasters and that of ointments; though no very definite rule for this consistence is, in fact, either given or observed.

Cera'tia. (From κερας, a horn, which its fruit resembles.) See *Ceratonia, siliqua.*

Ceratia diphyllus. See *Courbaril.*

Cera'ticum. See *Ceratonia siliqua.*

CERA'TO. (From κερας, a horn.) Some muscles have this word as a part of their names, from their shape.

Cerato-glossus. (From κερας, a horn, and γλωσσα, a tongue.) A muscle, so named from its shape and insertion into the tongue. See *Hyoglossus.*

Cerato hyoideus. See *Stylo-hyoideus.*

Cerato malagma. A cerate.

CERATOI'DES. From κερατος, the genitive of κερας, horn, and ειδος, appearance.) See *Cornea.*

CERATO'NIA. *Κερατωνια* of Galen and Paulus Ægineta; so called from its horn-like pod.) The name of a genus of plants. Class, *Polygamia*; Order, *Triæcia*.

CERATONIA SILIQUA. The systematic name of the plant which affords the sweet pod. *Ceratium*; *Ceratia*; *Siliqua dulcis*. The pods are about four inches in length, and as thick as one's finger, compressed and unequal, and mostly bent; they contain a sweet brown pulp, which is given in the form of decoction, as a pectoral in asthmatic complaints and coughs.

CERA'TUM. (*Ceratum*, *i.* m.; from *cera*, wax, because its principal ingredient is wax.) See *Cerate*.

CERATUM ALBUM. See *Ceratum cetacei*.

CERATUM CALAMINÆ. *Ceratum lapidis calaminaris*; *Ceratum epuloticum*. Calamine cerate. Take of prepared calamine, yellow wax, of each half a pound; olive oil, a pint. Mix the oil with the melted wax; then remove it from the fire, and, as soon as it begins to thicken, add the calamine, and stir it constantly until the mixture becomes cold. A composition of this kind was first introduced under the name of Turner's cerate. It is well calculated to promote the cicatrisation of ulcers.

CERATUM CANTHARIDIS. *Ceratum Lyttæ*. Cerate of blistering fly. Take of spermaceti cerate, six drachms; blistering flies, in very fine powder, a drachm. Having softened the cerate by heat, add the flies, and mix them together.

CERATUM CETACEI. *Ceratum spermatis ceti*. *Ceratum album*. Spermaceti cerate. Take of spermaceti, half an ounce; white wax, two ounces; olive oil, 4 fluid-ounces. Add the oil to the spermaceti and wax, previously melted together, and stir them until the mixture becomes cold. This cerate is cooling and emollient, and applied to excoriations, &c.: it may be used with advantage in all ulcers, where no stimulating substance can be applied, being extremely mild and unctuous.

CERATUM CITRINUM. See *Ceratum resinæ*.

CERATUM CONII. Hemlock cerate. ℞ unguenti conii, ℔j. Spermatis ceti, ℥ij. Ceræ albæ, ℥iii. Misce. One of the formulæ of St. Bartholomew's hospital, occasionally applied to cancerous, scrophulous, phagedenic, herpetic and other inveterate sores.

CERATUM EPULOTICUM. See *Ceratum calaminæ*.

CERATUM LAPIDIS CALAMINARIS. See *Ceratum calaminæ*.

CERATUM LITHARGYRI ACETATI COMPOSITUM. See *Ceratum plumbi compositum*.

CERATUM PLUMBI ACETATIS. *Unguentum cerussæ acetatæ*. Cerate of acetate of lead. Take of acetate of lead, powdered, two drachms; white wax, two ounces; olive oil, half a pint. Dissolve the wax in seven fluid-ounces of oil; then gradually add thereto the acetate of lead, separately rubbed down with the remaining oil, and stir the mixture with a wooden slice, until the whole has united. This cerate is cooling and desiccative.

CERATUM PLUMBI COMPOSITUM. *Ceratum lithargyri acetati compositum*. Compound cerate of lead. Take of solution of acetate of lead, two fluid-ounces and a half; yellow wax, four ounces; olive oil, nine fluid-ounces; camphor half a drachm. Mix the wax previously melted, with eight fluid-ounces of oil; then remove it from the fire, and, when it begins to thicken, add gradually the solution of acetate of lead, and constantly stir the mixture with a wooden slice, until it gets cold. Lastly, mix in the camphor, previously dissolved in the remainder of the oil. Its virtues are cooling, desiccative, resolvent against chronic rheumatism, &c. &c.; and as a proper application to superficial ulcers, which are inflamed.

CERATUM RESINÆ. *Ceratum resinæ flavæ*; *Ceratum citrinum*. Resin cerate. Take of yellow resin, yellow wax, of each a pound; olive oil, a pint. Melt the resin and wax together, over a slow fire; then add the oil, and strain the cerate, while hot, through a linen cloth. Digestive.

CERATUM SABINÆ. Savine cerate. Take of fresh leaves of savine, bruised, a pound; yellow wax, half a pound; prepared lard, two pounds. Having melted together the wax and lard, boil therein the savine leaves, and strain through a linen cloth. This article is of late introduction, for the purpose of keeping up a discharge from blistered surfaces. It was first described by Mr. Crowther, and has since been received into extensive use, because it does not produce the inconveniences that follow the constant application of the common blistering cerate. A thick white layer forms daily upon the part, which requires to be removed, that the cerate may be applied immediately to the surface from which the discharge is to be made.

CERATUM SAPONIS. Soap cerate. Take of hard soap, eight ounces; yellow wax, ten ounces; semi-vitreous oxide of lead, powdered, a pound; olive oil, a pint; vinegar, a gallon. Boil the vinegar, with the oxide of lead, over a slow fire, constantly stirring, until the union is complete; then add the soap, and boil it again in a similar manner, until the moisture is entirely evaporated; then mix in the wax, previously melted with the oil. Resolvent; against scrophulous tumours, &c. It is a convenient application in fractures, and may be used as an external dressing for ulcers.

CERATUM SIMPLEX. *Ceratum*. Simple cerate. Take of olive oil, four fluid-ounces; yellow wax, four ounces; having melted the wax, mix the oil with it.

CERATUM SPERMATIS CETI. See *Ceratum cetacei*.

CE'RBERUS. (Κερβερος; because, like the dog Cerberus, it has three heads, or principal ingredients, each of which is eminently active.) A fanciful name given to the compound powder of scammony.

CERCHNA'LEUM. (From κερχω, to make a noise.) A wheezing, or bubbling noise, made by the trachea, in breathing.

CE'RCHNOS. (From κερχω, to wheeze.) *Cerchnus*. Wheezing. Dr. Good applies it to a species of his genus *Rhonchus*, to designate a primary evil or disease; *rhonchus cerchnus*, or wheezing.

CERCHNO'DES. (From κερχω, to wheeze.) *Cerchodes*. One who labours under a dense breathing, accompanied with a wheezing noise.

CERCHO'DES. See *Cerchnodes*.

CE'RCIS. (Κερκις literally means the spoke of a wheel, and has its name from the noise which wheels often make; from κερκω, to shriek.) The radical bone of the fore-arm was formerly so called from its shape, like a spoke. Also a pestle, from its shape.

CERCO'SIS. (From κερκος, a tail.)

1. A polypus of the uterus.
2. An enlargement of the clitoris.

CE'REA. (From *cera*, wax.) The cerumen aurium, or wax of the ear.

CEREA'LIA. (Solemn feasts to the goddess Ceres.) All sorts of corn, of which bread or any nutritious substance is made, come under the head of *cerealia*, which term is applied by bromatologists as a genus.

Cerebe'lla urina. Paracelsus thus distinguishes urine which is whitish, of the colour of the brain, and from which he pretended to judge of some of its disorders.

CEREBE'LLUM. (Diminutive of *cerebrum.*) The little brain. A somewhat round viscus, of the same use as the brain; composed, like the brain, of a cortical and medullary substance, divided by a septum into a right and left lobe, and situated under the tentorium, in the inferior occipital fossæ. In the cerebellum are to be observed the *crura cerebelli*, the fourth ventricle, the *valvula magna cerebri*, and the *protuberantiæ vermiformes*.

CE'REBRUM. (*Quasi cerebrum;* from καρα, the head.) The brain. A large round viscus, divided superiorly into a *right* and *left hemisphere*, and inferiorly into *six lobes*, two anterior, two middle, and two posterior; situated within the cranium, and surrounded by the dura and pia mater, and tunica arachnoides. It is composed of a *cortical substance*, which is external; and a *medullary*, which is internal. It has three *cavities*, called *ventricles;* two anterior, or lateral, which are divided from each other by the *septum lucidum*, and in each of which is the *choroid plexus*, formed of blood-vessels; the third ventricle is a space between the thalami nervorum opticorum. The principal prominences of the brain are, the *corpus callosum*, a medullary eminence, conspicuous upon laying aside the hemispheres of the brain; the *corpora striata*, two striated protuberances, one in the anterior part of each lateral ventricle; the *thalami nervorum opticorum*, two whitish eminences behind the former, which terminate in the optic nerves; the *corpora quadrigemina*, four medullary projections, called by the ancients *nates* and *testes;* a little cerebrine tubercle lying upon the nates, called the *pineal gland;* and, lastly, the *crura cerebri*, two medullary columns which proceed from the basis of the brain to the *medulla oblongata*. The cerebral arteries are branches of the carotid and vertebral arteries. The veins terminate in *sinuses*, which return their blood into the internal jugulars. The use of the brain is to give off nine pairs of nerves, and the spinal marrow, from which thirty-one pairs more proceed, through whose means the various senses are performed, and muscular motion excited. It is also considered as the organ of the intellectual functions.

Vauquelin's analysis of the brain is in 100 parts: 80 water, 4.53 white fatty matter, 0.7 reddish fatty matter, 7 albumen, 1.12 osmazome, 1.5 phosphorus, 5.15 acids, salts, and sulphur.

Cerebrum elongatum. The medulla oblongata, and medulla spinalis.

CEREFO'LIUM. A corruption of *chærophyllum*. See *Scandix cerefolium.*

Cerefolium hispanicum. Sweet-cicely. See *Scandix odorata.*

Cerefolium sylvestre. See *Chærophyllum sylvestre.*

CERELÆ'UM. (From κηρος, wax, and ελαιον, oil.) A cerate, or liniment, composed of wax and oil. Also the oil of tar.

CEREOLUS. A wax bougie.

CE'REUS MEDICATUS. See *Bougie.*

CEREVI'SIA. (From *ceres*, corn, of which it is made.) Any liquor made from corn, especially ale and strong beer.

Cerevisiæ cataplasma. Into the grounds of strong beer, stir as much oatmeal as will make it of a suitable consistence. This is sometimes employed as a stimulant and antiseptic to mortified parts.

Cerevisiæ fermentum. See *Fermentum cerevisiæ.*

Ce'ria. (From *cereus*, soft, pliant.) The flat worms which breed in the intestines. See *Tænia.*

CERIN. 1. Subercerin. A peculiar substance which precipitates on evaporation from alcohol, which has been digested on cork.

2. The name given by Dr. John to the part of common wax which dissolves in alkohol.

3. The name of a variety of the mineral *allanite.*

Ce'rion. (From κηριον, a honey-comb.) An eruptive disorder of the head. See *Achor.*

CERITE. The siliciferous oxyde of cerium. A rare mineral of a rose-red colour, found only in the copper mine of Bastnacs, in Sweden. It consists of silica, oxide of cerium, and oxide of iron, lime, and carbonic acid.

CERIUM. The name of the metal, the oxide of which exists in the mineral cerite.

To obtain the oxide of the new metal, the cerite is calcined, pulverised, and dissolved in nitromuriatic acid. The filtered solution being neutralized with pure potassa, is to be precipitated by tartrate of potassa; and the precipitate, well washed, and afterwards calcined, is oxide of cerium.

Cerium is susceptible of two stages of oxidation; in the first it is white, and this by calcination becomes of a fallow-red.

The white oxide, exposed to the blowpipe, soon becomes red, but does not melt, or even agglutinate. With a large proportion of borax it fuses into a transparent globule.

The white oxide becomes yellowish in the open air, but never so red as by calcination, because it absorbs carbonic acid, which prevents its saturating itself with oxygen, and retains a portion of water, which diminishes its colour.

Alkalies do not act on it; but caustic potassa in the dry way takes part of the oxygen from the red oxide, so as to convert it into the white without altering its nature.

The protoxide of cerium is composed, by Hisinger, of 85.17 metal + 14.83 oxygen, and the peroxide of 79.3 metal + 20.7. The protoxide has been supposed a binary compound of cerium 5.75 + oxygen 1, and the peroxide a compound of 5.75×2 of cerium + 3 oxygen. An alloy of this metal with iron was obtained by Vauquelin.

The salts of cerium are white or yellow-coloured, have a sweet taste, yield a white precipitate with hydrosulphuret of potassa, but none with sulphuretted hydrogen; a milk-white precipitate, soluble in nitric and muriatic acids, with ferroprussiate of potassa, and oxalate of ammonia; none with infusion of galls, and a white one with arseniate of potassa.

CERO'MA. (From κηρος, wax.) *Ceronium.* Terms used by the ancient physicians for an unguent, or cerate, though originally applied to a particular composition which the wrestlers used in their exercises.

CEROPI'SSUS. (From κηρος, wax, and ϖισσα, pitch.) A plaster composed of pitch and wax.

Cerotum. Κερωτον. A cerate.

CERU'MEN. (*Cerumen;* diminutive, of *cera*, wax.) Wax. See *Cera.*

Cerumen aurium. *Cerea; Aurium sordes; Marmorata aurium; Cypsele; Cypselis; Fugile.* The waxy secretion of the ear, situated in the meatus auditorius externus.

CERU'SSA. (Arabian.) Cerusse. See *Plumbi subcarbonas.*

Cerussa acetata. See *Plumbi acetas.*

Cervi spina. See *Rhamnus catharticus.*

CERVI'CAL. (*Cervicalis;* from *cervix*, the neck.) Belonging to the neck; as cervical nerves, cervical muscles, &c.

Cervical artery. Arteria cervicalis. A branch of the subclavian.

Cervical vertebræ. The seven uppermost of the vertebræ, which form the spine. See *Vertebræ.*

Cervica'ria. (From *cervix*, the neck; so named because it was supposed to be efficacious in disorders and ailments of the throat and neck.) The herb throat-wort.

CE'RVIX. (*Cervix, vicis.* f.; quasi *cerebri via;* as being the channel of the spinal marrow.) 1. The neck. That part of the body which is between the head and shoulders.

2. Applied also to organs, or parts which have some extent, to distinguish their parts; as the *cervix uteri*, neck of the uterus; *cervix vesicæ*, neck of the bladder, neck of a bone, &c.

Cespititiæ plantæ. (From *cespes*, a sod, or turf.) The name of a class of plants in Sauvage's Methodus Foliorum, consisting of plants which have only radical leaves; as primrose, &c.

CESPITOSUS. (From *cespes*, a sod, or turf.) A plant is so called which produces many stems from one root, thereby forming a close thick carpet on the surface of the earth.

Cespitosæ paludes. Turf-bogs.

Cestri'tes. (From κεϛρον, betony.) Wine impregnated with betony.

CE'STRUM. (From κεϛρα, a dart; so called from the shape of its flowers, which resemble a dart; or because it was used to extract the broken ends of darts from wounds.) See *Betonica officinalis.*

CETA'CEUM. Spermaceti. See *Physeter macrocephalus.*

CE'TERACH. (Blanchard says this word is corrupted from *Pteryga*, ϖτηρυξ, q. v. as peteryga, ceteryga, and ceterach.) See *Asplenium ceterach.*

CETIC ACID. *Acidum ceticum.* The name given by Chevreul to a supposed peculiar principle of spermaceti, which he has lately found to be the substance he has called *margarine*, combined with a fatty matter.

CETINE. The name given by Chevreuil to spermaceti. See *Fat.*

CEVADIC ACID. By the action of potassa on the fat matter of the cevadilla, a plant that comes from Senegal, called by the French *petite orge*, there is obtained in the same way as the delphinic acid, an acid which is called the cevadic.

CEVADATE. A salt formed by the combination of the cevadic acid, with earthy, alkaline, and metallic bases.

Cevadilla. (Dim. of *ceveda*, barley. Spanish.) See *Veratrum sabatilla.*

Cayenne pepper. See *Capsicum.*

CEYLANITE. The name of the mineral called pleonaste, by Haüy, which comes from Ceylon, commonly in round pieces, but occasionally in crystals. It is of an indigo blue colour, and splendent internally.

CHABASITE. The name of a mineral found in the quarry of Alteberg, near Oberstein, in crystals, the primitive form of which is nearly a cube. It is white, or with a tinge of rose colour, and sometimes transparent.

Chacari'llæ cortex. See *Croton Cascarilla.*

CHÆROFO'LIUM. See *Scandix.*

CHÆROPHY'LLUM. (Χαιροφυλλον; from χαιρω, to rejoice, and φυλλον, a leaf: so called from the abundance of its leaves.) Chervil. 1. The name of a genus of plants in the Linnæan system. Class, *Pentandria;* Order, *Dyginia.*

2. The pharmacopœial name of some plants. See *Scandix*, and *Chærophyllum sylvestre.*

Chærophyllum sylvestre. The systematic name of the *Cicutaria*, or bastard hemlock. *Chærophyllum; caule lævi striato; geniculis tumidiusculis*, of Linnæus. It is often mistaken for the true hemlock. It may with great propriety be banished from the list of officinals, as it possesses no remarkable property.

Chæ'ta. (From χεω, to be diffused.) An obsolete name of the human hair.

CHALA'SIS. (From χαλαω, to relax.) Relaxation.

Chala'stica. (From χαλαω, to relax.) Medicines which relax.

CHALA'ZION. (From χαλαζα, a hail-stone.) *Chalaza; Chalazium; Grando.* An indolent, moveable tubercle on the margin of the eyelid, like a hail-stone. A species of hordeolum. It is that well-known affection of the eye, called a stye or stian. It is white, hard, and encysted, and differs from the *crithe*, another species, only in being moveable. Writers mention a division of Chalazion into scirrhous, cancerous, cystic, and earthy.

Cha'lbane. Καλβανη. Galbanum.

Chalca'nthum. (From χαλκος, brass, and ανθος, a flower.) Vitriol; or rather, vitriol calcined red. The flowers of brass.

Chalcei'on. A species of pimpinella.

Chalcoi'deum os. The os cuneiforme of the tarsus. See *Cuneiform bone.*

Chaleitis. See *Colcothar.*

Chali'cratum. (From χαλις, an old word that signifies pure wine, and κεραννυμι, to mix.) Wine mixed with water.

Chali'nos. *Chalinus.* That part of the cheeks, which, on each side, is contiguous to the angles of the mouth.

CHALK. A very common species of calcareous earth, or carbonate of lime, of a white colour. See *Creta.*

Chalk, black. Drawing slate, found in primitive mountains, and used in crayon drawing, whence its name.

Chalk, red. A clay, coloured with oxide of iron.

CHALK-STONE. A name given to the concretions in the hands and feet of people violently afflicted with the gout, from their resembling chalk, though chemically different. Dr. Wollaston first demonstrated their true composition to be uric acid combined with ammonia, and thus explained the mysterious pathological relation between gout and gravel.

Gouty concretions are soft and friable. They are insoluble in cold, but slightly in boiling water. An acid being added to this solution, seizes the soda, and the uric acid is deposited in small crystals. These concretions dissolve readily in water of potassa. An artificial compound may be made by triturating uric acid and soda with warm water, which exactly resembles gouty concretions in its chemical constitution.

CHALYBEATE. (*Chalybeatus;* from *chalybs*, iron, or steel.) Of or belonging to iron. A term given to any medicine into which iron enters; as chalybeate mixture, pills, waters, &c.

Chalybeate water. Any mineral water which abounds with iron; such as the water of Tunbridge, Spa, Pyrmont, Cheltenham, Scarborough, and Hartfel; and many others.

Chalybis rubigo præparata. See *Ferri subcarbonas.*

CHA′LYBS. (From *Chalybes*, a people in Pontus, who dug iron out of the earth.) *Acies.* Steel. The best, hardest, finest, and the closest-grained forged iron. As a medicine, steel differs not from iron. See *Iron.*

CHALYBS TARTARIZATUS. See *Ferrum tartarizatum.*

CHAMÆBA′LANUS. (From χαμαι, on the ground, and βαλανος, a nut.) Wood pea; Earth nut.

CHAMÆBU′XUS. (From χαμαι, on the ground, and πυξος, the box-tree.) The dwarf box-tree.

CHAMÆCE′DRUS. (From χαμαι, on the ground, and κεδρος, the cedar-tree.) *Chamæcedrys.* A species of dwarf abrotanum.

CHAMÆCI′SSUS. (From χαμαι, on the ground, and κισσος, ivy.) Ground-ivy.

CHAMÆCLE′MA. (From χαμαι, on the ground, and κλημα, ivy.) The ground-ivy.

CHAMÆCRISTA. The *Cassia chamæcrista* of Linnæus, a decoction of which drank liberally is said to be serviceable against the poison of the night-shade.

CHAMÆ′DRYS. (From χαμαι, on the ground, and δρυς, the oak; so called from its leaves resembling those of the oak.) See *Teucrium chamædrys.*

CHAMÆDRYS FRUTESCENS. A name for teucrium.

CHAMÆDRYS INCANA MARITIMA. See *Teucrium marum.*

CHAMÆDRYS PALUSTRIS. See *Teucrium scordium.*

CHAMÆDRYS SPURIA. See *Veronica officinalis.*

CHAMÆDRYS SYLVESTRIS. Wild germander. The *Veronica chamædrys.*

CHAMÆLE′A. (From χαμαι, on the ground, and ελαια, the olive-tree.) See *Daphne alpina.*

CHAMÆLÆA′GNUS. (From χαμαι, on the ground, and ελαιαγνος, the wild olive.) See *Myrica gale.*

CHAMÆ′LEON. (From χαμαι, on the ground, and λεων, a lion, *i. e.* dwarf lion.) 1. The chamæleon, an animal supposed to be able to change his colour at pleasure.

2. The name of many thistles, so named from the variety and uncertainty of their colours.

CHAMÆLEON ALBUM. See *Carlina acaulis.*

CHAMÆLEON VERUM. See *Cnicus.*

CHAMÆLEU′CE. (From χαμαι, on the ground, and λευκη, the herb colt's-foot.) See *Tussilago farfara.*

CHAMÆLI′NUM. (From χαμαι, on the ground, and λινον, flax.) Purging flax. See *Linum catharticum.*

CHAMÆME′LUM. (From χαμαι, on the ground, and μηλον, an apple; because it grows upon the ground, and has the smell of an apple.) See *Anthemis nobilis.*

CHAMÆMELUM CANARIENSE. The *Chrysanthemum frutescens* of Linnæus.

CHAMÆMELUM CHRYSANTHEMUM. The *Buphthalmum germanicum* of Linnæus.

CHAMÆMELUM FŒTIDUM. The *Anthemis cotula* of Linnæus.

CHAMÆMELUM NOBILE. See *Anthemis nobilis.*

CHAMÆMELUM VULGARE. See *Matricaria chamomilla.*

CHAMÆ′MORUS. (Χαμαιμορεα; from χαμαι, on the ground, and μορεα, the mulberry-tree.) See *Rubus chamamorus.*

CHAMÆPEU′CE. (From χαμαι, on the ground, and πευκη, the pine-tree.) See *Camphorosma Monspeliensis.*

CHAMÆ′PITYS. (*Chamæpitys, yos. f.*; from χαμαι, the ground, and πιτυς, the pine-tree.) See *Teucrium chamæpitys.*

CHAMÆPITYS MOSCHATA. The French ground pine. See *Teucrium iva.*

CHAMÆ′PLION. See *Erysimum alliaria.*

CHAMÆRA′PHANUS. (From χαμαι, on the ground, and ραφανος, the radish.) 1. The upper part of the root of apium, according to P. Ægineta. The smallage, or parsley.

2. The dwarf radish.

CHAMÆ′RIPHES. The *Chamærops humilis*, or dwarf palm. The fruit called wild dates, are adstringent.

CHAMÆRODODE′NDRON. (From χαμαι, on the ground, and ροδοδενδρον, the rose laurel.) The *Azalæa pontica* of Linnæus.

CHAMÆRUBUS. (From χαμαι, on the ground, and *rubus*, the bramble.) See *Rubus chamæmorus.*

CHAMÆSPA′RTIUM. (From χαμαι, on the ground, and σπαρτιον, Spanish broom. See *Genista tinctoria.*

CHAMBER. *Camara.* The space between the capsule of the crystalline lens and the cornea of the eye, is divided by the iris into two spaces, called chambers; the space before the iris is termed the anterior chamber; and that behind it, the posterior. They are filled with an aqueous fluid.

CHAMBERLEN, HUGH, a native of London, about the middle of the 17th century. He succeeded his father as a practitioner in midwifery, and had also two brothers in the same profession. They invented among them an instrument, the obstetric forceps, which greatly facilitated delivery in many cases, and often saved the child: but to him alone, as most distinguished, the merit has been usually ascribed. In 1683, he published a translation of Mauriceau's Observations, which was much sought after. The instrument procured him great celebrity in this, as well as other countries; and, with successive improvements by Smellie, &c. still continues to be esteemed one of the most valuable adjuvants in the obstetric art. The period of his death is not ascertained.

CHAMOMILE. See *Anthemis nobilis.*

Chamomile, stinking. See *Anthemis cotula.*

CHAMOMI′LLA. (From χαμαι, on the ground, and μηλον, an apple.) See *Anthemis nobilis.*

CHAMOMILLA NOSTRAS. See *Matricaria Chamomilla.*

CHAMOMILLA ROMANA. See *Anthemis.*

CHAMPIGNION. See *Agaricus pratensis.*

CHA′NCRE. (French. From καρκινος, cancer.) A sore which arises from the direct application of the venereal poison to any part of the body. Of course it mostly occurs on the genitals. Such venereal sores as break out from a general contamination of the system, in consequence of absorption, never have the term chancre applied to them.

Channelled leaf. See *Leaf.*

CHAOMA′NTIA SIGNA. So Paracelsus calls those prognostics that are taken from observations of the air; and the skill of doing this, he calls *Chaomancia.*

CHAO′SDA. Paracelsus uses this word as an epithet for the plague.

CHAPMAN, EDMUND, was born about the end of the 17th century; and, after becoming properly instructed as a surgeon and accoucheur, settled in London, and soon distinguished himself by his success in difficult labours. His plan consisted chiefly in turning the child, and delivering by the feet when any part but the head presented;

also in often availing himself of the forceps of Chamberlen, much improved by himself, and of which he had the merit of first giving an account to the public in his treatise on Midwifery, in 1732. He also ably defended the cause of the men-midwives against the attack of Douglas, in a small work, in 1737.

CHA'RABE. An Arabian name for amber.

CHA'RADRA. (From χαρασσω, to excavate.) The bowels, or sink of the body.

CHARAMAIS. The purging hazel-nut.

CHARANTIA. See *Momordica elaterium.*

CHARCOAL. When vegetable substances are exposed to a strong heat in the apparatus for distillation, the fixed residue is called charcoal. For general purposes, wood is converted into charcoal by building it up in a pyramidal form, covering the pile with clay or earth, and leaving a few air-holes, which are closed as soon as the mass is well lighted; and by this means the combustion is carried on in an imperfect manner.

In charring wood it has been conjectured, that a portion of it is sometimes converted into a pyrophorus, and that the explosions that happen in powder-mills are sometimes owing to this.

Charcoal is made on the great scale, by igniting wood in iron cylinders. When the resulting charcoal is to be used in the manufacture of gunpowder, it is essential that the last portion of vinegar and tar be suffered to escape, and that the reabsorption of the crude vapours be prevented, by cutting off the communication between the interior of the cylinders and the apparatus for condensing the pyrolignous acid, whenever the fire is withdrawn from the furnace. If this precaution be not observed, the gunpowder made with the charcoal would be of inferior quality.

In the third volume of Tilloch's Magazine, we have some valuable facts on charcoal, by Mr. Mushet. He justly observes, that the produce of charcoal in the small way, differs from that on the large scale, in which the quantity of char depends more upon the hardness and compactness of the texture of wood, and the skill of the workman in managing the pyramid of faggots, than on the absolute quantity of carbon it contains.

Clement and Desormes say, that wood contains one-half its weight of charcoal. Proust says, that good pit-coals afford 70, 75, or 80 per cent. of charcoal or coke; from which only two or three parts in the hundred of ashes remain after combustion.—*Tilloch's Mag.* vol. viii.

Charcoal is black, sonorous, and brittle, and in general retains the figure of the vegetable it was obtained from. If, however, the vegetable consist for the most part of water or other fluids, these in their extrication will destroy the connexion of the more fixed parts. In this case the quantity of charcoal is much less than in the former. The charcoal of oily or bituminous substances is of a light pulverulent form, and rises in soot. This charcoal of oils is called lamp-black. A very fine kind is obtained from burning alkohol. See *Carbon.*

CHA'RDONE. The artichoke.

CHARISTOLO'CHIA. (From χαρις, joy, and λοχια, the lochia; so named from its supposed usefulness to women in childbirth.) The plant mugwort. See *Artemisia vulgaris.*

CHARLTON, WALTER, was born in Somersetshire, 1619. After graduating at Oxford, where he distinguished himself by his learning, he was appointed physician to Charles I., and admitted a fellow of the Royal College of Physicians, in London. He had afterwards the honour of attending Charles II., and was one of the first members of the Royal Society. He was author of several publications, on medical and other subjects; the former of which contained little original matter, but had the merit of spreading the knowledge of the many improvements made about that period, particularly in anatomy and physiology; the principal of them are his "Exercitationes Pathologicæ," and his "Natural History of Nutrition, Life, and Voluntary Motion." In 1689, he was chosen president of the College, and held that office two years. He afterwards retired to Jersey, and died in 1707.

CHA'RME. (From χαιρω, to rejoice.) *Charmis.* A cordial mentioned by Galen.

CHA'RPIE. The French. For scraped linen, or lint.

CHA'RTA. (Chaldean.) 1. Paper.

2. The amnios, or interior fœtal membrane, was called the *charta virginea*, from its likeness to a piece of fine paper.

CHA'RTREUX, POUDRE DE. (So called because it was said to have been invented by some friars of the Carthusian order.) A name of the kermes mineral, or hydro-sulphuret of antimony.

CHA'SME. (From χαινω, to gape.) *Chasmus.* Oscitation or gaping.

CHASTE TREE. See *Agnus castus.*

CHA'TE. The *Cucumus ægyptia.*

Chay. See *Oldenlandia umbellata.*

Chaya. See *Oldenlandia umbellata.*

CHEEK-BONE. See *Jugale os.*

CHEESE. *Caseus.* The coagulum of milk. When prepared from rich milk, and well made, it is very nutritious in small quantities; but mostly indigestible when hard and ill-prepared, especially to weak stomachs. If any vegetable or mineral acid be mixed with milk, the cheese separates, and, if assisted by heat, coagulates into a mass. The quantity of cheese is less when a mineral acid is used. Neutral salts, and likewise all earthy and metallic salts, separate the cheese from the whey. Sugar and gum-arabic produce the same effect. Caustic alkalies will dissolve the curd by the assistance of a boiling heat, and acids occasion a precipitation again. Vegetable acids have very little solvent power upon curd. This accounts for a greater quantity of curd being obtained when a vegetable acid is used. But what answers best is rennet, which is made by macerating in water a piece of the last stomach of a calf, salted and dried for this purpose.

Scheele observed, that cheese has a considerable analogy to albumen, which it resembles in being coagulable by fire and acids, soluble in ammonia, and affording the same products by distillation or treatment with nitric acid. There are, however, certain differences between them. Rouelle observed likewise, a striking analogy between cheese and the gluten of wheat, and that found in the feculæ of green vegetables. By kneading the gluten of wheat with a little salt and a small portion of a solution of starch, he gave it the taste, smell, and unctuosity of cheese; so that after it had been kept a certain time, it was not to be distinguished from the celebrated Rochefort cheese, of which it had all the pungency. This caseous substance from gluten, as well as the cheese of milk, appears to contain acetate of ammonia, after it has been kept long enough to have undergone the requisite fermentation, as may be proved by examining it with sulphuric acid, and with potassa. The pungency of strong cheese, too, is destroyed by alkohol.

In the 11th volume of Tilloch's Magazine there is an excellent account of the mode of making Cheshire cheese, taken from the Agricultural Report of the country. "If the milk," says the reporter, "be set together very warm, the curd will be firm; in this case, the usual mode is to take a common case-knife, and make incisions across it, to the full depth of the knife's blade, at the distance of about one inch; and again cross-ways in the same manner, the incisions intersecting each other at right angles. The whey rising through these incisions is of a fine pale green colour. The cheese-maker and two assistants then proceed to break the curd: this is performed by their repeatedly putting their hands down into the tub; the cheese-maker, with the skimming-dish in one hand, breaking every part of it as they catch it, raising the curd from the bottom, and still breaking it. This part of the business is continued till the whole is broken uniformly small; it generally takes up about 40 minutes, and the curd is then left covered over with a cloth for about half an hour to subside. If the milk has been set cool together, the curd will be much more tender, the whey will not be so green, but rather of a milky appearance.

CHEILOCA'CE. (From χειλος, a lip, and κακον, an evil.) A swelling of the lips, ar canker in the mouth.

CHEIME'LTON. (From χειμα, winter.) A chilblain. See *Pernio*.

CHEIRA'NTHUS. (From χειρ, a hand, and ανθος, a flower; so named from the likeness of its blossoms to the fingers of the hand.) The name of a genus of plants in the Linnæan system. Class, *Tetradynamia*; Order, *Siliquosa*. The wall-flower.

CHEIRANTHUS CHEIRI. The systematic name of the wall-flower. *Leucoium luteum*; *Viola lutea*. Common yellow wall-flower. The flowers of this plant, *Cheiranthus; foliis lanceolatis, acutis, glabris; ramis angulatis; caule fruticoso*, of Linnæus, are recommended as possessing nervine and deobstruent virtues. They have a moderately strong, pleasant smell, and a nauseous, bitter, somewhat pungent taste.

CHEIRA'PSIA. (From χειρ, the hand, and απτομαι, to touch.) The act of scratching; particularly the scratching one hand with another, as in the itch.

CHEI'RI. (*Cheiri*, Arabian.) See *Cheiranthus Cheiri*.

CHEIRIA'TER. (From χειρ, the hand, and ιατρος, a physician.) A surgeon whose office it is to remove maladies by operations of the hand.

CHEIRI'SMA. (From χειριξομαι, to labour with the hand.) Handling. Also a manual operation.

CHEIRI'XIS. (From χειριζομαι, to labour with the hand.) The art of surgery.

CHEIRONO'MIA. (From χειρονομεω, to exercise with the hands.) An exercise mentioned by Hippocrates, which consisted of gesticulations with the hands, like our dumb-bells.

CHE'LA. (Χηλη, *forceps*; from χεω, to take.) 1. A forked probe, for drawing a polypus out of the nose.

2. A fissure in the feet, or other places.

3. The claw of crabs, which lays hold like forceps.

CHELÆ CANCRORUM. See *Cancer*.

CHELI'DON. The bend of the arm.

CHELIDO'NIUM. (From χελιδων, the swallow. It is so named from an opinion, that it was pointed out as useful for the eyes by swallows, who are said to open the eyes of their young by it; or because it blossoms about the time when swallows appear.) Celandine. A genus of plants in the Linnæan system. Class, *Polyandria*; Order, *Monogynia*. There is only one species used in medicine, and that rarely.

CHELIDONIUM MAJUS. *Papaver corniculatum, luteum; Curcum.* Tetterwort, and great celandine. The herb and root of this plant, *Chelidonium—pedunculis umbellatis*; of Linnæus, have a faint, unpleasant smell, and a bitter, acrid, durable taste, which is stronger in the roots than the leaves. They are aperient and diuretic, and recommended in icterus, when not accompanied with inflammatory symptoms. The chelidonium should be administered with caution, as it is liable to irritate the stomach and bowels. Of the dried root, from ʒss to ʒj is a dose; of the fresh root, infused in water, or wine, the dose may be about ℥ss. The decoction of the fresh root is used in dropsy, cachexy, and cutaneous complaints. The fresh juice is used to destroy warts, and films in the eyes; but, for the latter purpose, it is diluted with milk.

CHELIDONIUM MINUS. The pill-wort. See *Ranunculus ficaria*.

CHELO'NE. Χελωνη. 1. The tortoise.

2. An instrument for extending a limb, and so called because, in its slow motions, it represents a tortoise. This instrument is mentioned in Oribasius.

CHELO'NION. (From χελωνη, the tortoise; so called from its resemblance to the shell of a tortoise.) A hump, or gibbosity in the back.

CHELTENHAM. The name of a village, now become a large and populous town, in Gloucestershire. It is celebrated for its purging waters, the reputation of which is daily increasing, as it possesses both a saline and chalybeate principle. When first drawn, it is clear and colourless, but somewhat brisk; has a saline, bitterish, chalybeate taste. It does not keep, nor bear transporting to any distance; the chalybeate part being lost by precipitation of the iron, and in the open air it even turns fœtid. The salts, however, remain. Its heat in summer, was from 50° to 55° or 59°, when the medium heat of the atmosphere was nearly 15° higher. On evaporation, it is found to contain a calcareous earth, mixed with ochre and a purging salt. A general survey of the component parts of this water, according to a variety of analyses, shows that it is decidedly saline, and contains much more salt than most mineral waters. By far the greater part of the salts are of a purgative kind, and therefore an action on the bowels is a constant effect, notwithstanding the considerable quantity of selenite and earthy carbonates, which may be supposed to have a contrary tendency. Cheltenham water is, besides, one of the strongest chalybeates we are acquainted with. The iron is suspended entirely by the carbonic acid, of which gas the water contains about an eighth of its bulk; but from the abundance of earthy carbonates, and oxide of iron, not much of it is uncombined. It has, besides, a slight impregnation of sulphur, but so little as to be scarcely appreciable, except by very delicate tests. The sensible effects produced by this water, are generally, on first taking it, a degree of drowsiness, and sometimes headache, but which soon go off spontaneously, even previous to the operation on the bowels. A moderate dose acts powerfully, and speedily, as a cathartic, without occasioning griping, or leaving that faintness and languor which often follow the action of the rougher cathartics. It is principally on this account, but partly too from the salutary operation of the chalybeate, and perhaps the carbonic acid, that the Cheltenham water may be, in most cases, persevered in, for a considerable length of time, uninterruptedly, without producing any inconvenience to the body; and during its use, the appetite will be improved, the digestive organs strengthened, and the whole constitution invigorated. A dose of this water, too small to operate directly on the bowels, will generally determine pretty powerfully to the kidneys. As a purge, this water is drank from one to three pints; in general, from half a pint to a quart is sufficient. Half a pint will contain half a drachm of neutral purging salts, four grains of earthy carbonates, and selenite, about one-third of a grain of oxide of iron; together with an ounce in bulk of carbonic acid, and half an ounce of common air, with a little sulphuretted hydrogen. Cheltenham water is used, with considerable benefit, in a number of diseases, especially of the chronic kind, and particularly those called bilious: hence it has been found of essential service in the cure of glandular obstructions, and especially those that affect the liver, and the other organs connected with the functions of the alimentary canal. Persons who have injured their biliary organs, by a long residence in hot climates, and who are suffering under the symptoms, either of excess of bile or deficiency of bile, and an irregularity in its secretion, receive remarkable benefit from a course of this water, judiciously exhibited. Its use may be here continued, even during a considerable degree of debility; and from the great determination to the bowels, it may be employed with advantage to check the incipient symptoms of dropsy, and general anasarca, which so often proceed from an obstruction of the liver. In scrophulous affections, the sea has the decided preference; in painful affections of the skin, called scorbutic eruptions, which make their appearance at stated intervals, producing a copious discharge of lymph, and an abundant desquamation, in common with other saline purgative springs, this is found to bring relief; but it requires to be persevered in for a considerable time, keeping up a constant determination to the bowels, and making use of warm bathing. The season for drinking the Cheltenham water is during the whole of the summer months.

CHE'LYS. (Χελυς, a shell.) The breast is so called, as resembling, in shape and office, the shell of some fishes.

CHELY'SCION. (From χελυς, the breast.) A dry, short cough, in which the muscles of the breast are very sore.

CHE'MA. A measure mentioned by the Greek physicians, supposed to contain two small spoonfuls.

CHE'MIA. See *Chemistry*.

CHE'MICAL. Of or belonging to chemistry.

CHEMISTRY. (Χυμια, and sometimes χημια: *Chamia*, from *Chama*, to burn, Arab. this science being the examination of all substances by fire.) *Chemia*; *Chimia*; *Chymia*. The learned are not yet agreed as to the most proper definition of chemistry. Boerhaave seems to have ranked it among the arts. According to Macquer, it is a science, the object of which is to discover the nature and properties of all bodies by their analyses and combinations. Dr. Black says, it is a science which teaches, by experiments, the effects of heat and mixture on bodies; and Fourcroy defines it a science which teaches the mutual actions of all natural bodies on each other. "Chemistry," says Jacquin, "is that branch of natural philosophy which unfolds the nature of all material bodies, determines the number and properties of their component parts, and teaches us how those parts are united, and by what means they may be separated and recombined." Mr. Heron defines it, "That science which investigates and explains the laws of that attraction which takes place between the minute component particles of natural bodies." Dr. Ure's definition is, "the science which investigates the composition of material substances, and the permanent changes of constitution which their mutual actions produce." The objects to which the attention of chemists is directed, comprehend the whole of the substances that compose the globe.

CHEMO'SIS. (From χαινω, to gape; because it gives the appearance of a gap, or aperture.) Inflammation of the conjunctive membrane of the eye, in which the white of the eye is distended with blood, and elevated above the margin of the transparent cornea. In Cullen's Nosology, it is a variety of the ophthalmia membranarum, or an inflammation of the membranes of the eye.

CHENOPODIO-MORUS. (From *chenopodium* and *morus*, the mulberry; so called because it is a sort of chenopodium, with leaves like a mulberry.) The herb mulberry-blight. The *Blitum capitatum* of Linnæus.

CHENOPO'DIUM. (From χην, a goose, and ϖους, a foot; so called from its supposed resemblance to a goose's foot.) The name of a genus of plants in the Linnæan system. Class, *Pentandria*; Order, *Digynia*. The herb chenopody: goose's foot.

CHENOPODIUM AMBROSIOIDES. The systematic name of the Mexican tea-plant. *Botrys Mexicana*; *Botrys ambrosioides Mexicana*; *Chenopodium Mexicanum*; *Botrys Americana*. Mexico tea; Spanish tea and Artemisian botrys. *Chenopodium—foliis lanceolatis dentatis, racemis foliatis simplicibus*, of Linnæus. A decoction of this plant is recommended in paralytic cases. Formerly the infusion was drank instead of Chinese tea.

CHENOPODIUM ANTHELMINTICUM. The seeds of this plant, *Chenopodium—foliis ovato-oblongis dentatis, racemis aphyllis*, of Linnæus, though in great esteem in America, for the cure of worms, are seldom exhibited in this country. They are powdered and made into an electuary, with any proper syrup, or conserve.

CHENOPODIUM BONUS HENRICUS. The systematic name of the English mercury. *Bonus Henricus*; *Tota bona*; *Lapathum unctuosum*; *Chenopodium*; *Chenopodium—foliis triangulari-sagittatis, integerrimis, spicis compositis aphyllis axillaribus*, of Linnæus. The plant to which these names are given, is a native of this country, and common in waste grounds from June to August. It differs little from spinach when cultivated; and in many places the young shoots are eaten in spring like asparagus. The leaves are accounted emollient, and have been made an ingredient in decoctions for glysters. They are applied by the common people to flesh wounds and sores under the notion of drawing and healing.

CHENOPODIUM BOTRYS. The systematic name of the Jerusalem oak. *Botrys vulgaris*; *Botrys*; *Ambrosia*; *Artemisia chenopodium*; *Atriplex odorata*; *Atriplex suaveolens*; *Chenopodium—foliis oblongiis sinuatis, racemis nudis multifidis*, of Linnæus. This plant was formerly administered in form of decoction in some diseases of the chest; as humoral asthma, coughs, and catarrhs. It is now fallen into disuse.

CHENOPODIUM FŒTIDUM. See *Chenopodium vulvaria*.

CHENOPODIUM VULVARIA. The systematic name for the stinking orach. *Atriplex fœtida*; *Atriplex olida*; *Vulvaria*; *Garosmum*; *Raphex*; *Chenopodium fœtidum*; *Blitum fœtidum*.

The very fœtid smell of this plant, *Chenopodium —foliis integerrimis rhombeo ovatis, floribus conglomeratis axillaribus,* of Linnæus, induced physicians to exhibit it in hysterical diseases. It is now superseded by more active preparations. Messrs. Chevalier and Lasseigne have detected ammonia in this plant in an uncombined state, which is probably the vehicle of the remarkably nauseous odour which it exhales, strongly resembling that of putrid fish. When the plant is bruised with water, and the liquor expressed and afterwards distilled, we procure a fluid which contains the subcarbonate of ammonia, and an oily matter, which gives the fluid a milky appearance. If the expressed juice of the chenopodium be evaporated to the consistence of an extract, it is found to be alkaline; there seems to be acetic acid in it. Its basis is said to be of an albuminous nature. It is stated also to contain a small quantity of the substance which the French call osmazome, a little of an aromatic resin, and a bitter matter, soluble both in alkohol and water, as well as several saline bodies.

Che′ras. (From χεω, to pour out.) An obsolete name of struma, or scrophula.

Cherefo′lium. See *Scandix cerefolium.*

CHE′RMES. (Arabian.) A small berry, full of insects like worms: the juice of which was formerly made into a confection, called confectio alkermes, which has been long disused. The worm itself was also so called.

Chermes mineralis. Hydro-sulphuret of antimony.

Cherni′bium. *Chernibion.* In Hippocrates it signifies an urinal.

Chero′nia. (From Χειρων, the Centaur.) See *Chironia centaurium.*

CHERRY. See *Cerasa nigra,* and *Cerasa rubra.*

Cherry, bay. The *Lauro-cerasus.*

Cherry-laurel. The *Lauro-cerasus.*

Cherry, winter. The *Alkekengi.*

CHERVI′LLUM. See *Scandix cerefolium.*

CHESELDEN, William, was born in Leicestershire, 1688. After serving his apprenticeship to a surgeon at Leicester, he came to study at St. Thomas's hospital, to which he afterwards became surgeon. He began to give lectures at the early age of 22, and about the same period was elected Fellow of the Royal Society. Two years after, he published his "Anatomical Description of the Human Body," with some select cases in surgery, which passed through several editions; in one of which he detailed his success in the operation of lithotomy by the lateral method, as it is termed, which he found not so liable to failure as the high operation. He also gave in the Philosophical Transactions, an interesting account of a grown person whom he restored to sight after being blind from infancy; and furnished some other contributions to the same work. Besides being honourably distinguished by some of the French societies, he was appointed principal surgeon to Queen Caroline, to whom he dedicated his splendid work on the bones in 1733. He was four years after chosen surgeon to Chelsea Hospital, and retired from public practice, and lived to the age of 64.

CHESNUT. See *Æsculus* and *Fagus.*

Chesnut, horse. See *Æsculus Hippocastanum.*

Chesnut, sweet. See *Fagus castanea.*

Cheu′sis. (From χεω, to pour out.) Liquation. Infusion.

Cheva′stre. A double-headed roller, applied by its middle below the chin; then running on each side, it is crossed on the top of the head; then passing to the nape of the neck, is there crossed: it then passes under the chin, where crossing, it is carried to the top of the head, &c. until it is all taken up.

CHEYNE, George, was born in Scotland, 1670. After graduating in medicine, he came to London, at the age of 30, and published a Theory of Fevers, and five years after a work on Fluxions, which procured his election into the Royal Society; and this was soon followed by his "Philosophical Principles of Natural Religion." Being naturally inclined to corpulency, and indulging in free living, he became, when only of a middle age, perfectly unwieldy, with other marks of an impaired constitution; against which, finding medicines of little avail, he determined to abstain from all fermented liquors, and confine himself to a milk and vegetable diet. This plan speedily relieved the most distressing symptoms, which led him after a while to resume his luxuries; but finding his complaints presently returning, he resorted again to the abstemious plan; by a steady perseverance in which he retained a tolerable share of health to the advanced age of 72. In 1722, in a treatise on the gout, &c. he first inculcated this plan; and two years after greatly enlarged on the same subject, in his celebrated "Essay on Health and Long Life." His "English Malady, or Treatise on Nervous Diseases," which he regarded as especially prevalent in this country, a very popular work, published 1733, contains a candid and judicious narrative of his own case.

CHEZANA′NCE. (From χεζω, to go to stool, and *αναγκη,* necessity.) 1. Any thing that creates a necessity to go to stool.

2. In P. Ægineta, it is the name of an ointment, with which the anus is to be rubbed, for promoting stools.

CHI′A. (From Χιος, an island where they were formerly propagated.) 1. A sweet fig of the island of Cyprus, Chio, or Scio.

2. An earth from the island of Chio, formerly used in fevers.

3. A species of turpentine. See *Pistachia terebinthus.*

Chi′acus. (From Χιος, the island of Scio.) An epithet of a collyrium, the chief ingredient of which was wine of Chios.

Chi′adus. In Paracelsus it signifies the same as furunculus.

Chian turpentine. See *Pistacia terebinthus.*

Chia′smus. (From χιαζω, to form like the letter X, chi.) The name of a bandage, the shape of which is like the Greek letter X, *chi.*

CHIASTOLITE. The name of a mineral found in Brittany and Spain, somewhat like steatite.

Chia′stos. The name of a crucial bandage in Oribasius; so called from its resembling the letter X, *chi.*

Chia′stre. The name of a bandage for the temporal artery. It is a double-headed roller, the middle of which is applied to the side of the head, opposite to that in which the artery is opened, and, when brought round to the part affected, it is crossed upon the compress that is laid upon the wound, and then, the continuation is over the coronal suture, and under the chin; then crossing on the compress, the course is, as at the first, round the head, &c. till the whole roller is taken up.

Chi′bou. A spurious species of gumelemi, spoken of by the faculty of Paris, but not known in England.

Chefeur. Sulphur.

Chichi′na. Contracted from China chinæ. See *Cinchona.*

CHICKEN. The young of the gallinaceous order of birds, especially of the domestic fowl. See *Phasianus gallus.*

CHICKEN POX. See *Varicella.*

CHICKWEED. See *Alsine media.*

CHICOYNEAU, Francis, was born at Montpelier in 1672, the second son of a professor there, who becoming blind, he was appointed to discharge his duties, after taking his degrees in medicine. Having acquitted himself very creditably, he was deputed with other physicians to Marseilles in 1720, to devise measures for arresting the progress of the plague, which in the end almost depopulated that city. The zeal which he evinced on that occasion was rewarded by a pension; and on the death of his father-in-law, M. Chirac, in 1731, he was appointed to succeed him as first physician to the king; and received also other honours previously to his death in 1752. He published in 1721, in conjunction with the other physicians, an account of the plague at Marseilles, in which the opinion is advanced, that the disease was not contagious: and having received orders from the king to collect all the observations that had been made concerning that disease, he drew up an enlarged treatise with much candour, and containing a number of useful facts, which was made public in 1744.

CHI′LBLAIN. See *Pernio.*

Chi′li, balsamum de. Salmon speaks, but without any proof, of its being brought from Chili. The Barbadoes tar, in which are mixed a few drops of the oil of aniseed, is usually sold for it.

Chiliody′namon. (From χιλιοι, a thousand, and δυναμις, virtue.) In Dioscorides, this name is given on account of its many virtues. An epithet of the herb *Polemonium.* Most probably the wood sage, *Teucrium scorodonia* of Linnæus.

Chiliophyllon. (From χιλιοι, a thousand, and ψυλλον, a leaf, because of the great number of leaflets.) A name of the milfoil. See *Achillea millefolium.*

Chi′lon. Χειλων. An inflamed and swelled lip.

Chilpela′gua. A variety of capsicum.

Chime′thlon. A chilblain.

Chi′mia. See *Chemistry.*

Chimia′ter. (From χυμια, chemistry, and ιατρος, a physician.) A physician who makes the science of chemistry subservient to the purposes of medicine.

Chimo′lea laxa. Paracelsus means, by this word, the sublimed powder which is separated from the flowers of saline ores.

CHI′NA. (So named from the country of China, from whence it was brought.) See *Smilax China.*

China chinæ. A name given to the Peruvian bark.

China occidentalis. *China spuria nodosa; Smilax pseudo-China; Smilax Indica spinosa;* American or West-Indian China. This root is chiefly brought from Jamaica, in large round pieces full of knots. In scrophulous disorders, it has been preferred to the oriental kind. In other cases it is of similar but inferior virtue.

China supposita. See *Senecio pseudo-china.*

Chinchi′na. See *Cinchona.*

Chinchi′na Caribæa. See *Cinchona Caribæa.*

Chinchina de Santa Fe′. There are several species of bark sent from Santa Fé; but neither their particular natures, nor the trees which afford them, are yet accurately determined.

Chinchina Jamaicensis. See *Cinchona Caribæa.*

Chinchina rubra. See *Cinchona oblongifolia.*

Chinchina de St. Lucia. St. Lucia bark. See *Cinchona floribunda.*

CHINCOUGH. See *Pertussis.*

CHINE′NSIS. See *Citrus aurantium.*

Chinese Smilax. See *Smilax China.*

Chio turpentine. See *Pistacia terebinthus.*

Chi′oli. In Paracelsus it is synonymous with furunculus.

CHIRA′GRA. (From χειρ, the hand, and αγρα, a seizure.) The gout in the joints of the hand. See *Arthritis.*

CHIRO′NES. (From χειρ, the hand.) Small pustules on the hand and feet, inclosed in which is a troublesome worm.

CHIRO′NIA. (From *Chiron,* the Centaur, who discovered its use.) 1. The name of a genus of plants in the Linnæan system. Class, *Pentandria;* Order, *Monogynia.*

2. (From χειρ, the hand.) An affection of the hand, where it is troubled with chirones.

Chironia Centaurium. The systematic name of the officinal centaury. *Centaurium minus vulgare; Centaurium parvum; Centaurium minus; Libadium; Chironia—corollis quinquefidis infundibuliformibus, caule dichotomo, pistillo simplici,* of Linnæus. This plant is justly esteemed to be the most efficacious bitter of all the medicinal plants indigenous to this country. It has been recommended, by Cullen, as a substitute for gentian, and by several is thought to be a more useful medicine. The tops of the centaury plant are directed for use by the colleges of London and Edinburgh and are most commonly given in infusion; but they may also be taken in powder, or prepared into an extract.

Chiro′nium. (From Χειρων, the Centaur, who is said to have been the first who healed them.) A malignant ulcer, callous on its edges, and difficult to cure.

CHIROTHE′CA. (From χειρ, the hand, and τιθημι, to put.) A glove of the scarfskin, with the nails, which is brought off from the dead subject, after the cuticle is loosened by putrefaction, from the parts under it.

CHIR′URGIA. (From χειρ, the hand, and εργον, a work; because surgical operations are performed by the hand.) Chirurgery, or surgery.

Chi′ton. Χιτων. A coat, or membrane.

Chi′um. (From Χιος, the island where it was produced.) An epithet of a wine made at Scio.

Chlia′sma. (From χλιαινω, to make warm.) A warm fomentation.

CHLORA′SMA. (From χλωρος, green.) See *Chlorosis.*

CHLORATE. A compound of chloric acid with a salifiable basis.

CHLORIC ACID. *Acidum chloricum.* "It was first eliminated from salts containing it by Gay Lussac, and described by him in his admirable memoir on iodine, published in the 91st volume of the *Annales de Chimie.* When a current of chlorine is passed for some time through a solution of barytic earth in warm water, a substance called hyperoxymuriate of barytes by its first discoverer, Chenevix, is formed, as well as some common muriate. The latter is separated, by boiling phosphate of silver in the compound solution. The former may then be obtained by evaporation, in fine rhomboidal prisms. Into a dilute solution of this salt, Gay Lussac poured weak sulphuric acid. Though he added only a few drops of acid, not nearly enough to saturate the barytes, the liquid became sensibly acid, and not a bubble of oxygen escaped. By continuing to add sulphuric acid with caution, he succeeded in obtaining an acid liquid entirely free from sulphuric acid and barytes, and not precipitating nitrate of silver. It was chloric acid dissolved in water. Its characters are the following.

This acid has no sensible smell. Its solution in water is perfectly colourless. Its taste is very acid, and it reddens litmus without destroying the colour. It produces no alteration on solution of indigo in sulphuric acid. Light does not decompose it. It may be concentrated by a gentle heat, without undergoing decomposition, or without evaporating. It was kept a long time exposed to the air without sensible diminution of its quantity. When concentrated, it has something of an oily consistency. When exposed to heat, it is partly decomposed into oxygen and chlorine, and partly volatilized without alteration. Muriatic acid decomposes it in the same way, at the common temperature. Sulphurous acid, and sulphuretted hydrogen, have the same property; but nitric acid produces no change upon it. Combined with ammonia, it forms a fulminating salt, formerly described by M. Chenevix. It does not precipitate any metallic solution. It readily dissolves zinc, disengaging hydrogen; but it acts slowly on mercury. It cannot be obtained in the gaseous state. It is composed of 1 volume chlorine + 2.5 oxygen, or, by weight, of 100 chlorine, 111.70 oxygen, if we consider the specific gravity of chlorine to be 2.4866.

To the preceding account of the properties of chloric acid, M. Vauquelin has added the following. Its taste is not only acid, but astringent, and its odour, when concentrated, is somewhat pungent. It differs from chlorine, in not precipitating gelatine. When paper stained with litmus is left for some time in contact with it, the colour is destroyed. Mixed with muriatic acid, water is formed, and both acids are converted into chlorine. Sulphurous acid is converted into sulphuric, by taking oxygen from the chloric acid, which is consequently converted into chlorine.

Chloric acid combines with the bases, and forms the *chlorates*, a set of salts formerly known by the name of the *hyperoxygenated muriates*. They may be formed either directly by saturating the alkali or earth with the chloric acid, or by the old process of transmitting chlorine through the solutions of the bases, in Woolfe's bottles. In this case the water is decomposed. Its oxygen unites to one portion of the chlorine, forming chloric acid, while its hydrogen unites to another portion of chlorine, forming muriatic acid; and hence, chlorates and muriates must be contemporaneously generated, and must be afterwards separated by crystallization, or peculiar methods.

The *chlorate of potassa* or *hyperoxymuriate*, has been long known, and may be procured by receiving chlorine, as it is formed, into a solution of potassa. When the solution is saturated, it may be evaporated gently, and the first crystals produced will be the salt desired, this crystallising before the simple muriate, which is produced at the same time with it. Its crystals are in shining hexaëdral laminæ, or rhomboidal plates. It is soluble in 17 parts of cold water; and, but very sparingly, in alcohol. Its taste is cooling, and rather unpleasant. Its specific gravity is 2.0. 16 parts of water, at 60°, dissolve one of it, and 2½ of boiling water. The purest oxygen is extracted from this salt, by exposing it to a gentle red heat. One hundred grains yield about 115 cubic inches of gas. It consists of 9.5 chloric acid + 6 potassa = 15.5, which is the prime equivalent of the salt.

The effects of this salt on inflammable bodies are very powerful. Rub two grains into powder in a mortar, add a grain of sulphur, mix them well by gentle trituration, then collect the powder into a heap, and press upon it suddenly and forcibly with the pestle, a loud detonation will ensue. If the mixture be wrapped in strong paper, and struck with a hammer, the report will be still louder. Five grains of the salt, mixed in the same manner with two and a half of charcoal, will be inflamed by strong trituration, especially if a grain or two of sulphur be added, but without much noise. If a little sugar be mixed with half its weight of the chlorate, and a little strong sulphuric acid poured on it, a sudden and vehement inflammation will ensue; but this experiment requires caution, as well as the following. To one grain of the powdered salt in a mortar, add half a grain of phosphorus; it will detonate, with a loud report, on the gentlest trituration. In this experiment the hand should be defended by a glove, and great care should be taken that none of the phosphorus get into the eyes. Phosphorus may be inflamed by it under water, putting into a wine glass one part of phosphorus and two of the chlorate, nearly filling the glass with water, and then pouring in, through a glass tube reaching to the bottom, three or four parts of sulphuric acid. This experiment, too, is very hazardous to the eyes. If olive or linseed oil be taken instead of phosphorus, it may be inflamed by similar means on the surface of the water. This salt should not be kept mixed with sulphur, or perhaps any inflammable substance, as in this state it has been known to detonate spontaneously. As it is the common effect of mixtures of this salt with inflammable substances of every kind, to take fire on being projected into the stronger acids, Chenevix tried the experiment with it mixed with diamond powder in various proportions, but without success.

Chlorate of soda may be prepared in the same manner as the preceding, by substituting soda for potassa; but it is not easy to obtain it separate, as it is nearly as soluble as the muriate of soda, requiring only 3 parts of cold water. Vauquelin formed it, by saturating chloric acid with soda; 500 parts of the dry carbonate yielding 1100 parts of crystallized chlorate. It consists of 4 soda, 9.5 acid = 13.5, which is its prime equivalent. It crystallises in square plates, produces a sensation of cold in the mouth, and a saline taste; is slightly deliquescent, and in its other properties resembles the chlorate of potassa.

Barytes appears to be the next base in order of affinity for *this acid*. The best method of forming it is to pour hot water on a large quantity of this earth, and to pass a current of chlorine through the liquid kept warm, so that a fresh portion of barytes may be taken up as the former is saturated. This salt is soluble in about four parts of cold water, and less of warm, and crystallises like the simple muriate. It may be obtained, however, by the agency of double affinity; for phosphate of silver boiled in the solution will decompose the simple muriate, and the muriate of silver and phosphate of barytes being insoluble, will both fall down and leave the chlorate in solution alone. The phosphate of silver employed in this process must be perfectly pure, and not the least contaminated with copper.

The *chlorate of strontites* may be obtained in the same manner. It is deliquescent, melts immediately in the mouth, and produces cold; is more soluble in alcohol than the simple muriate, and crystallises in needles.

The *chlorate of lime*, obtained in a similar way, is extremely deliquescent, liquefies at a low heat, is very soluble in alcohol, produces much cold in solution, and has a sharp bitter taste.

Chlorate of ammonia is formed by double affinity, the carbonate of ammonia decomposing the earthy salts of this genus, giving up its carbonic acid to their base, and combining with their acid into chlorate of ammonia, which may be obtained by evaporation. It is very soluble both in water and alcohol, and decomposed by a moderate heat.

The *chlorate of magnesia* much resembles that of lime.

To obtain *chlorate of alumina*, Chenevix put some alumina, precipitated from the muriate, and well washed, but still moist, into a Woolfe's apparatus, and treated it as the other earths. The alumina shortly disappeared; and on pouring sulphuric acid into the liquor, a strong smell of chloric acid was perceivable; but on attempting to obtain the salt pure by means of phosphate of silver, the whole was decomposed, and nothing but chlorate of silver was found in the solution.”

CHLORIC OXIDE. Deutoxide of chlorine. When sulphuric acid is poured upon hyper-oxymuriate of potassa in a wine-glass, very little effervescence takes place, but the acid gradually acquires an orange colour, and a dense yellow vapour, of a peculiar and not disagreeable smell, floats on the surface. These phenomena led Sir H. Davy to believe, that the substance extricated from the salt is held in solution by the acid. After various unsuccessful attempts to obtain this substance in a separate state, he at last succeeded by the following method: About 60 grains of the salt are triturated with a little sulphuric acid, just sufficient to convert them into a very solid paste. This is put into a retort, which is heated by means of hot water. The water must never be allowed to become boiling hot, for fear of explosion. The heat drives off the new gas, which may be received over mercury. This new gas has a much more intense colour than euchlorine. It does not act on mercury. Water absorbs more of it than euchlorine. Its taste is astringent. It destroys vegetable blues without reddening them. When phosphorus is introduced into it, an explosion takes place. When heat is applied, the gas explodes with more violence, and producing more light than euchlorine. When thus exploded, two measures of it are converted into nearly three measures, which consist of a mixture of one measure chlorine, and two measures oxygen. Hence it is composed of one atom chlorine and four atoms oxygen.

Deutoxide of chlorine has a peculiar aromatic odour, unmixed with any smell of chlorine. A little chlorine is always absorbed by the mercury during the explosion of the gas. Hence the small deficiency of the resulting measure is accounted for. At common temperatures none of the simple combustibles which Sir H. Davy tried, decomposed the gas, except phosphorus. The taste of the aqueous solution is extremely astringent and corroding, leaving for a long while a very disagreeable sensation. The action of liquid nitric acid on the chlorate of potassa affords the same gas, and a much larger quantity of this acid may be safely employed than of the sulphuric. But as the gas must be procured by solution of the salt, it is always mixed with about one-fifth of oxygen.”

CHLORIDE. A compound of chlorine with different bodies.

Chloride of azot. See *Nitrogen.*

CHLO'RINE. (So called from χλωρος, green, because it is of a green colour.) Oxygenated muriatic acid. “The introduction of this term, marks an era in chemical science. It originated from the masterly researches of Sir H. Davy on the oxymuriatic acid gas of the French school; a substance which, after resisting the most powerful means of decomposition which his sagacity could invent, or his ingenuity apply, he declared to be, according to the true logic of chemistry, an elementary body, and not a compound of muriatic acid and oxygen, as was previously imagined, and as its name seemed to denote. He accordingly assigned to it the term chlorine, descriptive of its colour; a name now generally used. The chloridic theory of combustion, though more limited in its applications to the chemical phenomena of nature, than the antiphlogistic of Lavoisier, may justly be regarded as of equal importance to the advancement of the science itself. When we now survey the Transactions of the Royal Society for 1808, 1809, 1810, and 1811, we feel overwhelmed with astonishment at the unparalleled skill, labour, and sagacity, by which the great English chemist, in so short a space, prodigiously multiplied the objects and resources of the science, while he promulgated a new code of laws, flowing from views of elementary action, equally profound, original, and sublime. The importance of the revolution produced by his researches on chlorine, will justify us in presenting a detailed account of the steps by which it has been effected. How entirely the glory of this great work belongs to Sir H. Davy, notwithstanding some invidious attempts in this country to tear the well-earned laurel from his brow, and transfer it to the French chemists, we may readily judge by the following decisive facts.

The second part of the Phil. Trans. for 1809, contains researches on oxymuriatic acid, its nature and combinations, by Sir H. Davy, from which the following interesting extracts are taken.

‘In the Bakerian lecture for 1808,’ says he, ‘I have given an account of the action of potassium upon muriatic acid gas, by which more than one-third of its volume of hydrogen is produced; and I have stated, that muriatic acid can in no instance be procured from oxymuriatic acid, or from dry muriates, unless water or its elements be present.

‘In the second volume of the *Mémoires D'*Arcueil, Gay Lussac and Thenard have detailed an extensive series of facts, upon muriatic acid, and oxymuriatic acid. Some of their experiments are similar to those I have detailed in the paper just referred to; others are peculiarly their own, and of a very curious kind: their general conclusion is, that muriatic acid gas contains about one-quarter of its weight of water; and that oxymuriatic acid is not decomposable by any substances but hydrogen, or such as can form triple combinations with it.

‘One of the most singular facts that I have observed on this subject, and which I have before referred to, is that charcoal, even when ignited to whiteness in oxymuriatic or muriatic acid gases, by the voltaic battery, effects no change in them, if it has been previously freed from hydrogen, by intense ignition *in vacuo.*

'This experiment, which I have several times repeated, led me to doubt of the existence of oxygen in that substance, which has been supposed to contain it, above all others, in a loose and active state; and to make a more rigorous investigation, than had hitherto been attempted for its detection.'

He then proceeds to interrogate nature, with every artifice of experiment and reasoning, till he finally extorts a confession of the true constitution of this mysterious muriatic essence. The above paper, and his Bakerian lecture, read before the Royal Society in Nov. and Dec. 1810, and published in the first part of their Transactions for 1811, present the whole body of evidence for the undecompounded nature of oxymuriatic acid gas, thenceforward styled chlorine; and they will be studied in every enlightened age and country, as a just and splendid pattern of inductive Baconian logic. These views were slowly and reluctantly admitted by the chemical philosophers of Europe.

In 1812 Sir H. Davy published his Elements of Chemical Philosophy, containing a systematic account of his new doctrines concerning the combination of simple bodies. Chlorine is there placed in the same rank with oxygen, and finally removed from the class of acids. In 1813, Thenard published the first volume of his *Traité de Chimie Elémentaire Théorique et Pratique.* This distinguished chemist, the fellow-labourer of Gay Lussac, in those able researches on the alkalies and oxymuriatic acid, which form the distinguished rivalry of the French school, to the brilliant career of Sir H. Davy, states, at p. 584 of the above volume, the composition of oxymuriatic acid as follows:

'*Composition.* The oxygenated muriatic gas contains the half of its volume of oxygen gas, not including that which we may suppose in muriatic acid. It thence follows, that it is formed of 1.9183 of muriatic acid, and 0.5517 of oxygen; for the specific gravity of oxygenated muriatic gas is 2.47, and that of oxygen gas 1.1034.'—'Chenevix first determined the proportion of its constituent principles. Gay Lussac and Thenard determined it more exactly, and showed that we could not decompose the oxygenated muriatic gas, but by putting it in contact with a body capable of uniting with the *two* elements of this gas, or with muriatic acid. They announced at the same time that they could explain all the phenomena which it presents, by considering it as a simple or as a compound body. However, this last opinion appeared more probable to them. Davy, on the contrary, embraced the first, admitted it exclusively, and sought to fortify it by experiments which are peculiar to him.' P. 585.

In the second volume of Thenard's work, published in 1814, he explains the mutual action of chlorine and ammonia gases, solely on the oxygenous theory. 'On peut démontrer par ce dernier procédé, que le gas muriatique oxigéné doit contenir la moitié de son volume d'oxigène, uni à l'acide muriatique.' P. 147.—In the 4th volume, which appeared in 1816, we find the following passages: '*Oxygenated muriatic gas.*—Oxygenated muriatic gas, in combining with the metals, gives rise to the neutral muriates. Now, 107.6 of oxide of silver, contain 7.6 of oxygen, and absorb 26.4 of muriatic acid, to pass to the state of neutral muriate. Of consequence, 348 of this last acid supposed dry, and 100 of oxygen, form this gas. But the sp. gr. of oxygen, is 1.1034, and that of oxygenated muriatic gas is 2.47; hence, this contains the half of its volume of oxygen.' P. 52.

The force of Sir H. Davy's demonstrations, pressing for six years on the public mind of the French philosophers, now begins to transpire in a note to the above passage.—'We reason here,' says Thenard, 'obviously on the hypothesis, which consists in regarding oxygenated muriatic gas as a compound body.' This pressure of public opinion becomes conspicuous at the end of the volume. Among the additions, we have the following decisive evidence of the lingering attachment to the old theory of Lavoisier and Berthollet.—'A pretty considerable number of persons who have subscribed for this work, desiring a detailed explanation of the phenomena which oxygenated muriatic gas presents, on the supposition that this gas is a simple body, we are now going to explain these phenomena, on this supposition, by considering them attentively. The oxygenated muriatic gas will take the name of *chlorine;* its combinations with phosphorus, sulphur, azot, metals, will be called *chlorures;* the muriatic acid, which results from equal parts in volume of hydrogen and oxygenated muriatic gases, will be *hydrochloric acid;* the superoxygenated muriatic acid will be *chlorous acid;* and the hyperoxygenated muriatic, *chloric acid;* the first, comparable to the hydriodic acid, and the last to the iodic acid.' In fact, therefore, we evidently see, that so far from the *chloridic* theory originating in France, as has been more than insinuated, it was only the researches on iodine, so admirably conducted by Gay Lussac, that, by their auxiliary attack on the oxygen hypothesis, eventually opened the minds of its adherents to the evidence long ago advanced by Sir H. Davy. It will be peculiarly instructive, to give a general outline of that evidence, which has been mutilated in some systematic works on chemistry, or frittered away into fragments.

Sir H. Davy subjected oxymuriatic gas to the action of many simple combustibles, as well as metals, and from the compounds formed, endeavoured to eliminate oxygen, by the most energetic powers of affinity and voltaic electricity, but without success, as the following abstract will show.

If oxymuriatic acid gas be introduced into a vessel exhausted of air, containing tin, and the tin be gently heated, and the gas in sufficient quantity, the tin and the gas disappear, and a limpid fluid, precisely the same as Libavius's liquor, is formed: If this substance is a combination of muriatic acid and oxide of tin, oxide of tin ought to be separated from it by means of ammonia. He admitted ammoniacal gas over mercury to a small quantity of the liquor of Libavius; it was absorbed with great heat, and no gas was generated; a solid result was obtained, which was of a dull white colour; some of it was heated, to ascertain if it contained oxide of tin; but the whole volatilized, producing dense pungent fumes.

Another experiment of the same kind, made with great care, and in which the ammonia was used in great excess, proved that the liquor of Libavius cannot be decompounded by ammonia; but that it forms a new combination with this substance.

He made a considerable quantity of the solid compound of oxymuriatic acid and phosphorus by combustion, and saturated it with ammonia, by heating it in a proper receiver filled with ammoniacal gas, on which it acted with great energy, producing much heat; and they formed a white opaque powder. Supposing that this substance was composed of the dry muriates and phosphates of ammonia; as muriate of ammonia is very volatile, and as ammonia is driven off from phosphoric acid by a heat below redness, he conceived that, by igniting the product obtained, he should procure phosphoric acid; he therefore introduced some of the powder into a tube of green glass, and heated it to redness, out of the contact of air, by a spirit lamp; but found, to his great surprise, that it was not at all volatile, nor decomposable at this degree of heat, and that it gave off no gaseous matter.

The circumstance, that a substance composed principally of oxymuriatic acid, and ammonia, should resist decomposition or change at so high a temperature, induced him to pay particular attention to the properties of this new body.

It has been said, and taken for granted by many chemists, that when oxymuriatic acid and ammonia act upon each other, water is formed: he several times made the experiment, and was convinced that this is not the case.

He mixed together sulphurated hydrogen in a high degree of purity, and oxymuriatic acid gas, both dried, in equal volumes. In this instance the condensation was not 1-40; sulphur, which seemed to contain a little oxymuriatic acid, was formed on the sides of the vessel; no vapour was deposited, and the residual gas contained about 19-20 of muriatic acid gas, and the remainder was inflammable.

When oxymuriatic acid is acted upon by nearly an equal volume of hydrogen, a combination takes place between them, and muriatic acid gas results. When muriatic acid gas is acted on by mercury, or any other metal, the oxymuriatic acid is attracted from the hydrogen by the stronger affinity of the metal, and an oxymuriate, exactly similar to that formed by combustion, is produced.

The action of water upon those compounds which have been usually considered as muriates, or as dry muriates, but which are properly combinations of oxymuriatic acid with inflammable bases, may be easily explained, according to these views of the subject. When water is added in certain quantities to Libavius's liquor, a solid crystallized mass is obtained, from which oxide of tin and muriate of ammonia can be procured by ammonia. In this case, oxygen may be conceived to be supplied to the tin, and hydrogen to the oxymuriatic acid.

The compound formed by burning phosphorus in oxymuriatic acid, is in a similar relation to water. If that substance be added to it, it is resolved into two powerful acids; oxygen, it may be supposed, is furnished to the phosphorus to form phosphoric acid, hydrogen to the oxymuriatic acid to form common muriatic acid gas.

He caused strong explosions from an electrical jar to pass through oxymuriatic gas, by means of points of platina, for several hours in succession; but it seemed not to undergo the slighest change.

He electrized the oxymuriates of phosphorus and sulphur for some hours, by the power of the voltaic apparatus of 1000 double plates. No gas separated, but a minute quantity of hydrogen, which he was inclined to attribute to the presence of moisture in the apparatus employed; for he once obtained hydrogen from Libavius's liquor by a similar operation. But he ascertained that this was owing to the decomposition of water adhering to the mercury; and in some late experiments made with 2000 double plates, in which the discharge was from platina wires, and in which the mercury used for confining the liquor was carefully boiled, there was no production of any permanent elastic matter.

Few substances, perhaps, have less claim to be considered as acid, than oxymuriatic acid. As yet we have no right to say that it has been decompounded; and as its tendency of combination is with pure inflammable matters, it may possibly belong to the same class of bodies as oxygen.

May it not in fact be a *peculiar* acidifying and dissolving principle, forming compounds with combustible bodies, analogous to acids containing oxygen or oxides, in their properties and powers of combination; but differing from them, in being for the most part decomposable by water? On this idea, muriatic acid may be considered as having hydrogen for its basis, and oxymuriatic acid for its acidifying principle; and the phosphoric sublimate as having phosphorus for its basis, and oxymuriatic acid for its acidifying matter; and Libavius's liquor, and the compounds of arsenic with oxymuriatic acid, may be regarded as analogous bodies. The combinations of oxymuriatic acid with lead, silver, mercury, potassium, and sodium, in this view, would be considered as a class of bodies related more to oxides than acids, in their powers of attraction.—*Bak. Lec.* 1809.

On the Combinations of the Common Metals with Oxygen and Oxymuriatic Gas.

Sir H. used in all cases small retorts of green glass, containing from three to six cubical inches, furnished with stop-cocks. The metallic substances were introduced, the retort exhausted and filled with the gas to be acted upon, heat was applied by means of a spirit lamp, and after cooling, the results were examined, and the residual gas analysed.

All the metals that he tried, except silver, lead, nickel, cobalt, and gold, when heated, burnt in the oxymuriatic gas, and the volatile metals with flame. Arsenic, antimony, tellurium, and zinc, with a white flame, mercury with a red flame. Tin became ignited to whiteness, and iron and copper to redness; tungsten and manganese to dull redness; platina was scarcely acted upon at the heat of fusion of the glass.

The product from mercury was corrosive sublimate. That from zinc was similar in colour to that from antimony, but was much less volatile.

Silver and lead produced horn-silver and horn-lead; and bismuth, butter of bismuth.

In acting upon metallic oxides by oxymuriatic gas, he found that those of lead, silver, tin, copper, antimony, bismuth, and tellurium, were decomposed in a heat below redness, but the oxides of the volatile metals more readily than those of the fixed ones. The oxides of cobalt and nickel were scarcely acted upon at a dull red heat. The red oxide of iron was not affected at a strong red heat, whilst the black oxide was readily decomposed at a much lower temperature; arsenical acid underwent no change at the greatest heat that could be given it in the glass retort, whilst the white oxide readily decomposed.

In cases where oxygen was given off, it was found exactly the same in quantity as that which had been absorbed by the metal. Thus, two grains of red oxide of mercury absorbed 9-10 of a cubical inch of oxymuriatic gas, and afforded 0.45 of oxygen. Two grains of dark olive oxide from calomel decomposed by potassa, absorbed about 94-100 of oxymuriatic gas, and afforded 24-100 of oxygen, and corrosive sublimate was produced in both cases.

In the decomposition of the white oxide of zinc, oxygen was expelled exactly equal to half the volume of the oxymuriatic acid absorbed. In the case of the decomposition of the black oxide of iron, and the white oxide of arsenic, the changes that occurred were of a very beautiful kind; no oxygen was given off in either case, but butter of arsenic and arsenical acid formed in one instance, and the ferruginous sublimate and red oxide of iron in the other.

General Conclusions and Observations, illustrated by Experiments.

Oxymuriatic gas combines with inflammable bodies, to form simple binary compounds; and in these cases, when it acts upon oxides, it either produces the expulsion of their oxygen, or causes it to enter into new combinations.

If it be said that the oxygen arises from the decomposition of the oxymuriatic gas, and not from the oxides, it may be asked, why it is always the quantity contained in the oxide? and why in some cases, as those of the peroxides of potassium and sodium, it bears no relation to the quantity of gas?

If there existed any acid matter in oxymuriatic gas, combined with oxygen, it ought to be exhibited in the fluid compound of one proportion of phosphorus, and two of oxymuriatic gas; for this, on such an assumption, should consist of muriatic acid (on the old hypothesis, free from water) and phosphorous acid; but this substance has no effect on litmus paper, and does not act under common circumstances, on fixed alkaline bases, such as dry lime or magnesia. Oxymuriatic gas, like oxygen, must be combined in large quantity with peculiar inflammable matter, to form acid matter. In its union with hydrogen, it instantly reddens the driest litmus paper, though a gaseous body. Contrary to acids, it expels oxygen from protoxides, and combines with peroxides.

When potassium is burnt in oxymuriatic gas, a dry compound is obtained. If potassium combined with oxygen is employed, the whole of the oxygen is expelled, and the same compound formed. It is contrary to sound logic to say, that this exact quantity of oxygen is given off from a body not known to be compound, when we are certain of its existence in another; and all the cases are parallel.

Scheele explained the bleaching powers of the oxymuriatic gas, by supposing that it destroyed colours by combining with phlogiston. Berthollet considered it as acting by supplying oxygen. He made an experiment, which seems to prove that the pure gas is incapable of altering vegetable colours, and that its operation in bleaching depends entirely upon its property of decomposing water, and liberating its oxygen.

He filled a glass globe, containing dry powdered muriate of lime, with oxymuriatic gas. He introduced some dry paper tinged with litmus that had been just heated, into another globe containing dry muriate of lime: after some time this globe was exhausted, and then connected with the globe containing the oxymuriatic gas, and by an appropriate set of stop-cocks, the paper was exposed to the action of the gas. No change of colour took place, and after two days there was scarcely a perceptible alteration.

Some similar paper dried, introduced into gas that had not been exposed to muriate of lime, was instantly rendered white.

It is generally stated in chemical books, that oxymuriatic gas is capable of being condensed and crystallised at a low temperature. He found by several experiments that this is not the case. The solution of oxymuriatic gas in water freezes more readily than pure water, but the pure gas dried by muriate of lime undergoes no change whatever, at a temperature of 40 below 0° of Fahrenheit. The mistake seems to have arisen from the exposure of the gas to cold in bottles containing moisture.

He attempted to decompose boracic and phosphoric acids by oxymuriatic gas, but without success; from which it seems probable, that the attractions of boracium and phosphorus for oxygen are stronger than for oxymuriatic gas. And from the experiments already detailed, iron and arsenic are analogous in this respect, and probably some other metals.

Potassium, sodium, calcium, strontium, barium, zinc, mercury, tin, lead, and probably silver, antimony, and gold, seem to have a stronger attraction for oxymuriatic gas than for oxygen.

‘ To call a body which is not known to contain oxygen, and which cannot contain muriatic acid, oxymuriatic acid, is contrary to the principles of that nomenclature in which it is adopted; and an alteration of it seems necessary to assist the progress of discussion, and to diffuse just ideas on the subject. If the great discoverer of this substance had signified it by any simple name, it would have been proper to have recurred to it; but dephlogisticated marine acid is a term which can hardly be adopted in the present advanced era of the science.

‘ After consulting some of the most eminent chemical philosophers in this country, it has been judged most proper to suggest a name founded upon one of its obvious and characteristic properties—its colour, and to call it *chlorine* or *chloric* gas.

‘ Should it hereafter be discovered to be compound, and even to contain oxygen, this name can imply no error, and cannot necessarily require a change.

‘ Most of the salts which have been called muriates, are not known to contain any muriatic acid, or any oxygen. Thus Libavius's liquor, though converted into a muriate by water, contains only tin and oxymuriatic gas, and horn-silver seems incapable of being converted into a true muriate.’—*Bak. Lec.* 1811.

We shall now exhibit a summary view of the preparation and properties of chlorine.

Mix in a mortar 3 parts of common salt and 1 of black oxide of manganese. Introduce them into a glass retort, and add 2 parts of sulphuric acid. Gas will issue, which must be collected in the water-pneumatic trough. A gentle heat will favour its extrication. In practice, the above pasty-consistenced mixture is apt to boil over into the neck. A mixture of liquid muriatic acid and manganese is therefore more convenient for the production of chlorine. A very slight heat is adequate to its expulsion from the retort. Instead of manganese, red oxide of mercury, or puce-coloured oxide of lead, may be employed.

This gas, as we have already remarked, is of a greenish-yellow colour, easily recognized by daylight, but scarcely distinguishable by that of candles. Its odour and taste are disagreeable, strong, and so characteristic, that it is impossible to mistake it for any other gas. When we breathe it, even much diluted with air, it occasions a sense of strangulation, constriction of the *thorax*, and a copious discharge from the nostrils. If respired in larger quantity, it excites violent coughing, with spitting of blood, and would speedily destroy the individual, amid violent distress. Its specific gravity is 2.4733. This is better inferred from the specific gravities of hydrogen and muriatic acid gases, than from the direct weight of chlorine, from the impossibility of confining it over mercury. One volume of hydrogen, added to one of chlorine, form two of the acid gas. Hence, if from twice the specific gravity of muriatic gas = 2.5427, we subtract that of hydrogen = 0.0694, the difference 2.4733 is the sp. gr. of chlorine. 100 cubic inches at mean pressure and temperature weigh 75½ grains. See *Gas*.

In its perfectly dry state, it has no effect on dry vegetable colours. With the aid of a little moisture, it bleaches them into a yellowish-white. Scheele first remarked this bleaching property; Berthollet applied it to the art of bleaching in France; and from him Mr. Watt introduced its use into Great Britain.

If a lighted wax taper be immersed rapidly into this gas, it consumes very fast, with a dull reddish flame, and much smoke. The taper will not burn at the surface of the gas. Hence, if slowly introduced, it is apt to be extinguished. The alkaline metals, as well as copper, tin, arsenic, zinc, antimony, in fine laminæ or filings, spontaneously burn in chlorine. Metallic chlorides result. Phosphorus also takes fire at ordinary temperatures, and is converted into a chloride. Sulphur may be melted in the gas without taking fire. It forms a liquid chloride, of a reddish colour. When dry, it is not altered by any change of temperature. Enclosed in a phial with a little moisture, it concretes into crystalline needles, at 40° Fahr.

According to Thenard, water condenses, at the temperature of 68° F. and at 29.92 barom. 1½ times its volume of chlorine, and forms *aqueous* chlorine, formerly called liquid oxymuriatic acid. This combination is best made in the second bottle of a Woolfe's apparatus, the first being charged with a little water, to intercept the muriatic acid gas, while the third bottle may contain potassa-water or milk of lime, to condense the superfluous gas. Thenard says, that a kilogramme of salt is sufficient for saturating from 10 to 12 litres of water. These measures correspond to 2⅓ lbs. avoirdupois, and to from 21 to 25 pints English. There is an ingenious apparatus for making aqueous chlorine, described in Berthollet's Elements of Dyeing, vol. i.; which, however, the happy substitution of slaked lime for water, by Mr. Charles Tennant of Glasgow, has superseded, for the purposes of manufacture. It congeals by cold at 40° Fahr. and affords crystallised plates, of a deep yellow, containing a less proportion of water than the liquid combination. Hence when chlorine is passed into water at temperatures under 40°, the liquid finally becomes a concrete mass, which at a gentle heat liquefies with effervescence, from the escape of the excess of chlorine. When steam and chlorine are passed together through a red-hot porcelain tube, they are converted into muriatic acid and oxygen. A like result is obtained by exposing aqueous chlorine to the solar rays; with this difference, that a little chloric acid is formed. Hence aqueous chlorine should be kept in a dark place. Aqueous chlorine attacks almost all the metals at an ordinary temperature, forming muriates or chlorides, and heat is evolved. It has the smell, taste, and colour of chlorine; and acts, like it, on vegetable and animal colours. Its taste is somewhat astringent, but not in the least degree acidulous.

When we put in a perfectly dark place, at the ordinary temperature, a mixture of chlorine and hydrogen, it experiences no kind of alteration, even in the space of a great many days. But if, at the same low temperature, we expose the mixture to the diffuse light of day, by degrees the two gases enter into chemical combination, and form muriatic acid gas. There is no change in the *volume* of the mixture, but the change of its *nature* may be proved, by its rapid absorbability by water, its not exploding by the lighted taper, and the disappearance of the chlorine hue. To produce the complete discoloration, we must expose the mixture finally for a few minutes to the sunbeam. If exposed at first to this intensity of light, it explodes with great violence, and instantly forms muriatic acid gas. The same explosive combination is produced by the electric spark and the lighted taper. Thenard says, a heat of 392° is sufficient to cause the explosion. The proper proportion is an equal volume of each gas. Chlorine and nitrogen combine into a remarkable detonating compound, by exposing the former gas to a solution of an ammoniacal salt. Chlorine is the most powerful agent for destroying contagious *miasmata*. The disinfecting phials of Morveau evolve this gas."—*Ure*.

CHLORITE. A mineral usually friable or very easy to pulverize, composed of a multitude of little spangles, or shining small grains, falling to powder under the pressure of the fingers. There are four sub-species.

1. *Chlorite earth.* In green, glimmering, and somewhat pearly scales with a shining green streak.

2. *Common chlorite.* A massive mineral of a blackish-green colour, a shining lustre, and a foliated fracture passing into earthy.

3. *Chlorite slate.* A massive, blackish-green mineral, with a resinous lustre, and curve slaty or scaly-foliated fracture.

4. *Foliated chlorite.* Colour between mountain and blackish-green.

CHLORIODATE. A compound of the chloriodic acid with a salifiable basis.

CHLORIODE ACID. *Acidum chloriodatum.* See *Chloriodic acid.*

CHLORIODIC ACID. *Acidum chlorodicum. Chloriode acid.* Sir H. Davy formed it, by admitting chlorine in excess to known quantities of iodine, in vessels exhausted of air, and repeatedly heating the sublimate. Operating in this way, he found that iodine absorbs less than one-third of its weight of chlorine.

Chloriodic acid is a very volatile substance, formed by the sublimation of iodine in a great excess of chlorine, is of a bright yellow colour; when fused it becomes of a deep orange, and when rendered elastic, it forms a deep orange-coloured gas. It is capable of combining with much iodine when they are heated together; its colour, becomes, in consequence, deeper, and the chloriodic acid and the iodine rise together in the elastic state. The solution of the chloriodic acid in water, likewise dissolves large quantities of iodine, so that it is possible to obtain a fluid containing very different proportions of iodine and chlorine.

When two bodies so similar in their characters, and in the compounds they form, as iodine and chlorine, act upon substances at the same time, it is difficult, Sir H. observes, to form a judgment of the different parts that they play in the new chemical arrangement produced. It appears most probable, that the acid property of the chloriodic compound depends upon the combination of the two bodies; and its action upon solutions of the alkalies and the earths may be easily explained, when it is considered that chlorine has a greater tendency than iodine to form double compounds with the metals, and that iodine has a greater tendency than chlorine to form triple compounds with oxygen and the metals.

A triple compound of this kind with sodium may exist in sea water, and would be separated with the first crystals that are formed by its evaporation. Hence, it may exist in common salt.

Sir H. Davy ascertained, by feeding birds with bread soaked with water, holding some of it in solution, that it is not poisonous like iodine itself. —*Ure's Ch. Dict.*

CHLORO-CARBONOUS ACID. "The term chloro-carbonic which has been given to this compound is incorrect, leading to the belief of its being a compound of chlorine and acidified charcoal, instead of being a compound of chlorine and the protoxide of charcoal. Chlorine has no immediate action on carbonic oxide, when they are exposed to each other in common day-light over mercury: not even when the electric spark is passed through them. Experiments made by Dr. John Davy, in the presence of his brother Sir H. Davy, prove that they combine rapidly when exposed to the direct solar beams, and one volume of each is condensed into one volume of the compound. The resulting gas possesses very curious properties, approaching to those of an acid. From the peculiar potency of the sunbeam in effecting this combination, Dr. Davy called it *phosgene gas*. The constituent gases, dried over muriate of lime, ought to be introduced from separate reservoirs into an exhausted globe, perfectly dry, and exposed for fifteen minutes to bright sunshine, or for twelve hours to day-light. The colour of the chlorine disappears, and on opening the stop-cock belonging to the globe under mercury recently boiled, an absorption of one-half the gaseous volume is indicated. The resulting gas possesses properties perfectly distinct from those belonging to either carbonic oxide or chlorine.

It does not fume in the atmosphere. Its odour is different from that of chlorine, something like that which might be imagined to result from the smell of chlorine combined with that of ammonia. It is in fact more intolerable and suffocating than chlorine itself, and affects the eyes in a peculiar manner, producing a rapid flow of tears, and occasioning painful sensations.

It reddens dry litmus paper; and condenses four volumes of ammonia into a white salt, while heat is evolved. This ammoniacal compound is neutral, has no odour, but a pungent saline taste; is deliquescent, decomposable by the liquid mineral acids, dissolves without effervescing in vinegar, and sublimes unaltered in muriatic, carbonic, and sulphurous acid gases. Sulphuric acid resolves it into carbonic and muriatic acids, in the proportion of two in volume of the latter, and one of the former. Tin, zinc, antimony, and arsenic, heated in chloro-carbonous acid, abstract the chlorine, and leave the carbonic oxide expanded to its original volume. There is neither ignition nor explosion takes place, though the action of the metals is rapid. Potassium acting on the compound gas produces a solid chloride and charcoal. White oxide of zinc, with chloro-carbonous acid, gives a metallic chloride, and carbonic acid. Neither sulphur, phosphorus, oxygen, nor hydrogen, though aided by heat, produce any change on the acid gas. But oxygen and hydrogen together, in due proportions, explode in it; or mere exposure to water converts it into muriatic and carbonic acid gases.

From its completely neutralising ammonia, which carbonic acid does not; from its separating carbonic acid from the subcarbonate of this alkali, while itself is not separable by the acid gases or acetic acid, and its reddening vegetable blues, there can be no hesitation in pronouncing the chloro-carbonous compound to be an acid. Its saturating powers indeed surpass every other substance. None condenses so large a proportion of ammonia.

One measure of alcohol condenses twelve of chloro-carbonous gas without decomposing it; and acquires the peculiar odour and power of affecting the eyes.

To prepare the gas in a pure state, a good air-pump is required, perfectly tight stop-cocks, dry gases, and dry vessels. Its specific gravity may be inferred from the specific gravities of its constituents, of which it is the sum. Hence $2.4733 + 0.9722 = 3.4455$, is the specific gravity of chloro-carbonous gas; and 100 cubic inches weigh 105.15 grains. It appears that when hydrogen, carbonic oxide, and chlorine, mixed in equal volumes, are exposed to light, muriatic and chloro-carbonous acids are formed, in equal proportions, indicating an equality of affinity.

The paper in the Phil. Trans. for 1812, from which the preceding facts are taken, does honour to the school of Sir H. Davy. Gay Lussac and Thenard, as well as Dr. Murray, made controversial investigations on the subject at the same time, but without success. Thenard has, however, recognized its distinct existence and properties, by the name of *carbo-muriatic* acid, in the 2d volume of his System, published in 1814, where he considers it as a compound of muriatic and carbonic acids, resulting from the mutual actions of the *oxygenated muriatic acid* and carbonic oxide."—*Ure.*

CHLOROCYANIC ACID. *Acidum chlorocyanicum.* Chloroprussic acid. "When hydrocyanic acid is mixed with chlorine, it acquires new properties. Its odour is much increased. It no longer forms prussian blue with solutions of iron, but a green precipitate, which becomes blue by the addition of sulphurous acid. Hydrocyanic acid thus altered had acquired the name of *oxyprussic*, because it was supposed to have acquired oxygen. Gay Lussac subjected it to a minute examination, and found that it was a compound of equal volumes of chlorine and cyanogen, whence he proposed to distinguish it by the name of chlorocyanic acid. To prepare this compound, he passed a current of chlorine into solution of hydrocyanic acid, till it destroyed the colour of sulphate of indigo; and by agitating the liquid with mercury, he deprived it of the excess of chlorine. By distillation, afterwards, in a moderate heat, an elastic fluid is disengaged which possesses the properties formerly assigned to *oxyprussic* acid. This, however, is not pure chlorocyanic acid, but a mixture of it with carbonic acid, in proportions which vary so much, as to make it difficult to determine them.

When hydrocyanic acid is supersaturated with chlorine, and the excess of this last is removed by mercury, the liquid contains chlorocyanic and muriatic acids. Having put mercury into a glass jar until it was 3-4ths full, he filled it completely with that acid liquid, and inverted the jar in a vessel of mercury. On exhausting the receiver of an air-pump containing this vessel, the mercury sunk in the jar, in consequence of the elastic fluid disengaged. By degrees the liquid itself was entirely expelled, and swam on the mercury on the outside. On admitting the air the liquid could not enter the tube, but only the mercury, and the whole elastic fluid condensed, except a small bubble. Hence it was concluded that chlorocyanic acid was not a permanent gas, and that, in order to remain gaseous under the pressure of the air, it must be mixed with another gaseous substance.

The mixture of chlorocyanic and carbonic acids, has the following properties. It is colourless. Its smell is very strong. A very small quantity of it irritates the pituitory membrane, and occasions tears. It reddens litmus, is not inflammable, and does not detonate when mixed with twice its bulk of oxygen or hydrogen. Its density, determined by calculation, is 2.111. Its aqueous solution does not precipitate nitrate of silver, nor barytes water. The alkalies absorb it rapidly, but an excess of them is necessary to destroy its odour. If we then add an acid, a strong effervescence of carbonic acid is produced, and the odour of chlorocyanic acid is no longer perceived. If we add an excess of lime to the acid solution, ammonia is disengaged in abundance. To obtain the green precipitate from solution of iron, we must begin by mixing chlorocyanic acid with that solution. We then add a little potassa, and at last a little acid. If we add the alkali before the iron, we obtain no green precipitate.

Chlorocyanic acid exhibits with potassium almost the same phenomena as cyanogen. The inflammation is equally slow and the gas diminishes as much in volume."—*Ure.*

CHLOROPHANE. A violet fluor spar found in Siberia.

CHLOROPHILE. The name lately given by Pelletier and Caventou to the green matter of the leaves of plants. They obtained it by pressing, and then washing in water the substance of many leaves, and afterwards treating it with alkohol. A matter was dissolved, which, when separated by evaporation, and purified by washing in hot water, appeared as a deep green resinous substance. It dissolves entirely in alkohol, æther, oils, or alkalies; it is not altered by exposure to air; it is softened by heat, but does not melt; it burns with flame, and leaves a bulky coal. Hot water slightly dissolves it. Acetic acid is the only acid that dissolves it in great quantity. If an earthy or metallic salt be mixed with the alkoholic solution, and then alkali or alkaline subcarbonate be added, the oxide or earth is thrown down in combination with much of the green substance, forming a lake. These lakes appear moderately permanent when exposed to the air. It is supposed to be a peculiar proximate principle.

CHLOROPRUSSIC ACID. See *Chlorocyanic acid.*

CHLORO'SIS. (From χλωρος, green, pale; from, χλοα, or, χλοη, *herba virens:* and hence χλωρασμα, and χλωριασις, *viror, pallor;* so called from the yellow-greenish look those have who are affected with it.) *Febris alba; Febris amatoria; Icterus albus; Chlorasma.* The green-sickness. A genus of disease in the class *Cachexiæ*, and order *Impetigines* of Cullen. It is a disease which affects young females who labour under a retention or suppression of the menses. Heaviness, listlessness to motion, fatigue on the least exercise, palpitations of the heart, pains in the back, loins, and hips, flatulency and acidities in the stomach and bowels, a preternatural appetite for chalk, lime, and various other absorbents, together with many dyspeptic symptoms, usually attend on this disease. As it advances in its progress, the face becomes pale, or assumes a yellowish hue; the whole body is flaccid, and likewise pale; the feet are affected with œdematous swellings; the breathing is much hurried by any considerable exertion of the body; the pulse is quick, but small; and the person is apt to be affected with many of the symptoms of hysteria. To procure a flow of the menses, proves in some cases a very difficult matter; and where the disease has been of long standing, various morbid affections of the viscera are often brought on, which at length prove fatal. Dissections of those who have died of chlorosis, have usually shown the ovaria to be in a scirrhous, or dropsical state. In some cases, the liver, spleen, and mesenteric glands, have likewise been found in a diseased state.

The cure is to be attempted by increasing the tone of the system, and exciting the action of the uterine vessels. The first may be effected by a generous nutritive diet, with the moderate use of wine; by gentle and daily exercise, particularly on horse-back; by agreeable company, to amuse and quiet the mind; and by tonic medicines, especially the preparations of iron, joined with myrrh, &c. Bathing will likewise help much to strengthen them, if the temperature of the bath be made gradually lower, as the patient bears it; and sometimes drinking the mineral chalybeate waters may assist. The bowels must be kept regular, and occasionally a gentle emetic will prepare for the tonic plan. The other object of stimulating the uterine vessels may be attained by the exercises of walking and dancing; by frequent friction of the lower extremities; by the pediluvium, hip-bath, &c.; by electric shocks, passed through the region of the uterus: by active purgatives, especially those formulæ containing aloes, which acts particularly on the rectum. These means may be resorted to with more probability of success, when there appear efforts of the system to produce the discharge, the general health having been previously improved. Various remedies have been dignified with the title of emmenagogues, though mostly little to be depended on, as madder, &c. In obstinate cases, the tinctura lyttæ, or savine, may be tried, but with proper caution, as the most likely to avail.

CHLOROUS ACID. *Acidum chlorosum.* See *Chlorous oxide.*

CHLOROUS OXIDE. Euchorine. Protoxide of chlorine. "To prepare it, put chlorate of potassa into a small retort, and pour in twice as much muriatic acid as will cover it, diluted with an equal volume of water. By the application of a gentle heat, the gas is evolved. It must be collected over mercury.

Its tint is much more lively, and more yellow than chlorine, and hence its discoverer named it *euchlorine.* Its smell is peculiar, and approaches to that of burnt sugar. It is not respirable. It is soluble in water, to which it gives a lemon colour. Water absorbs 8 or 10 times its volume of this gas. Its specific gravity is to that of common air nearly as 2.40 to 1; for 100 cubic inches weigh, according to Sir H. Davy, between 74 and 75 grains. If the compound gas result from 4 volumes of chlorine + 2 of oxygen, weighing 12.1154, which undergo a condensation of one-sixth, then the specific gravity comes out 2.423, in accordance with Sir H. Davy's experiments. He found that 50 measures detonated in a glass tube over pure mercury, lost their brilliant colour, and became 60 measures, of which 40 were chlorine and 20 oxygen.

This gas must be collected and examined with much prudence, and in very small quantities. A gentle heat, even that of the hand, will cause its explosion, with such force as to burst thin glass. From this facility of decomposition, it is not easy to ascertain the action of combustible bodies upon it. None of the metals that burn in chlorine act upon this gas at common temperatures; but when the oxygen is separated, they then inflame in the chlorine. This may be readily exhibited, by first introducing into the protoxide a little Dutch foil, which will not be even tarnished; but on applying a heated glass tube to the gas in the neck of the bottle, decomposition instantly takes place, and the foil burns with brilliancy. When already in chemical union, therefore, chlorine has a stronger attraction for oxygen than for metals; but when insulated, its affinity for the latter is predominant. Protoxide of chlorine has no action on mercury, but chlorine is rapidly condensed by this metal into calomel. Thus, the two gases may be completely separated. When phosphorus is introduced into the protoxide, it instantly burns, as it would do in a mixture of two volumes of chlorine and one of oxygen; and a chloride and acid of phosphorus result. Lighted taper and burning sulphur likewise instantly decompose it. When the protoxide freed from water is made to act on dry vegetable colours, it gradually destroys them, but first gives to the blues a tint of red; from which, from its absorbability by water, and the strongly acrid taste of the solution approaching to sour, it may be considered as approximating to an acid in its nature."—*Ure.*

Chlorure of iodine. The chloriodic acid.

CHNUS. (From χνανω, to grind, or rasp.) 1. Chaff; Bran.

2. Fine wool, or lint, which is, as it were, rasped from lint.

CHO′ANA. (Χοανα, a funnel; from χεω to pour out.) 1. A funnel.

2. The infundibulum of the kidney and brain.

CHO′ANUS. A furnace made like a funnel, for melting metals.

CHO′COLATE. (Dr. Alston says this word is compounded of two Indian words, *choco*, sound, and *atte*, water; because of the noise made in its preparation.) An article of diet prepared from the cacao-nut; highly nourishing, particularly when boiled with milk and eggs. It is frequently recommended as a restorative in cases of emaciation and consumption. See *Theobroma cacao.*

Chocolate-tree. See *Theobroma cocao.*

CHŒ′NICIS. (From χοινικις, the nave of a wheel.) The trepan; so called by Galen and P. Ægineta.

CHŒ′RADES. (From χοιρος, a swine.) The same as scrofula.

CHŒRADOLE′THRON. (From χοίρος, a swine, and ολεθρος, destruction; so named from its being dangerous if eaten by hogs.) Hogbane. A name in Aëtius for the *Xanthium*, or louse-bur.

CHOI′RAS. (From χοιρος, a swine; so called because hogs are diseased with it.) See *Scrofula.*

Choke damp. The name given by miners to a noxious air. See *Carbonic acid.*

CHO′LADES. (From χολη, the bile.) So the smaller intestines are called, because they contain bile.

CHOLÆUS. (χολαιος, bilious.) Biliary.

CHOLA′GO. See *Cholas.*

CHOLAGO′GA. (From χολη, bile, and αγω, to evacuate.) *Cholegon.* By cholagogues, the ancients meant only such purging medicines as expelled the internal fæces, which resembled the cystic bile in their yellow colour, and other properties.

CHO′LAS. (From χολη, the bile.) *Cholago.* All the cavity of the right hypochondrium and part of the neighbourhood, is so called, because it contains the liver which is the strainer of the gall.

CHO′LE. Χολη. The bile.

CHOLE′DOCHUS. (From χολη, bile, and, δεχομαι, to receive; receiving or retaining the gall.) The receptacle of bile.

CHOLEDOCHUS DUCTUS. *Ductus communis choledochus.* The common biliary duct, which conveys both cystic and hepatic bile into the intestinum duodenum.

CHOLE′GON. See *Cholagoga.*

CHOLERA. (Celsus derives it from χολε and ρεω, literally a flow of bile, and Trallian, from χολας, and ρεω, intestinal flux.) *Diarrhœa cholerica; Felliflua passio.* A genus of disease arranged by Cullen in the class *Neuroses*, and order *Spasmi.* It is a purging and vomiting of bile, with anxiety, painful gripings, spasms of the abdominal muscles, and those of the calves of the legs. There are two species of this genus: 1. *Cholera spontanea*, which happens, in hot seasons, without any manifest cause. 2. *Cholera accidentalis*, which occurs after the use of food that digests slowly, and irritates. In warm climates it is met with at all seasons of the year, and its occurrence is very frequent; but in England, and other cold climates, it is apt to be most prevalent in the middle of summer, particularly in the month of August; and the violence of the disease has usually been observed to be greater in proportion to the intenseness of the heat. It usually comes on with soreness, pain, distension, and flatulency in the stomach and intestines, succeeded quickly by a severe and frequent vomiting, and purging of bilious matter, heat, thirst, a hurried respiration, and frequent but weak and fluttering pulse. When the disease is not violent, these symptoms, after continuing for a day or two, cease gradually, leaving the patient in a debilitated and exhausted state; but where the disease proceeds with much violence, there arises great depression of strength, with cold clammy sweats, considerable anxiety, a hurried and short respiration, and hiccups, with a sinking and irregularity of the pulse, which quickly terminate in death; an event that not unfrequently happens within the space of twenty-four hours.

The appearances generally observed on dissection are, a quantity of bilious matter in the primæ viæ; the ducts of the liver relaxed and distended; and several of the viscera have been found displaced, probably by the violent vomiting. In the early period of the disease, when the strength is not much exhausted, the object is to lessen the irritation, and facilitate the discharge of the bile, by tepid demulcent liquids, frequently exhibited. It will likewise be useful to procure a determination to the surface by fomentations to the abdomen, the pediluvium, or even the warm bath. But where the symptoms are urgent, and the patient appears rapidly sinking from the continued vomiting, violent pain, &c. it is necessary to give opium freely, but in a small bulk; from one to three grains, or even more, in a table spoonful of linseed infusion, or with an effervescing saline draught; which must be repeated at short intervals, every hour perhaps, till relief be obtained. Sometimes, where the stomach could not be got to retain the opium, it has answered in the form of clyster; or a liniment containing it may be rubbed into the abdomen; or a blister, applied over the stomach, may lessen the irritability of that organ. Afterwards the bile may be allowed to evacuate itself downwards; or mild aperients, or clysters, given, if necessary, to promote its discharge. When the urgent symptoms are relieved, the strength must be restored by gentle tonics, as the aromatic bitters, calumba, and the like, with a light nutritious diet: strong toast and water is the best drink, or a little burnt brandy may be added if there is much languor. Exposure to cold must be carefully avoided particularly keeping the abdomen and the feet warm; and great attention is necessary to regulate the bowels, and procure a regular discharge of bile, lest a relapse should happen. It will also be proper to examine the state of the abdomen, whether pressure give pain at any part, because inflammation in the primæ viæ is very liable to supervene, often in an insidious manner; should that be the case, leeches, blistering the part and other suitable means, must be promptly resorted to.

CHOLE'RICA. (From χολερα, the cholera.) Medicines which relieve the cholera.

CHOLESTERIC ACID. "When the fat matter of the human biliary calculi is treated with nitric acid, which Chevreuil proposed to call cholesterine, there is formed a peculiar acid, which is called the cholesteric. To obtain it, the cholesterine is heated with its weight of concentrated nitric acid, by which it is speedily attacked and dissolved. There is disengaged at the same time, much oxyde of azot; and the liquor on cooling, and especially on the addition of water, lets fall a yellow matter, which is the cholesteric acid impure, or impregnated with nitric acid. It may be purified by repeated washings in boiling water. However, after having washed it, it is better to effect its fusion in the midst of hot water; to add to it a small quantity of carbonate of lead; to let the whole boil for some hours, decanting and renewing the water from time to time; then to put the remaining dried mass in contact with alkohol, and to evaporate the alkoholic solution. The residuum now obtained is the purest possible cholesteric acid.

This acid has an orange-yellow colour when it is in mass; but it appears in white needles, when dissolved in alkohol, and left to spontaneous evaporation. Its taste is very feeble, and slightly styptic; its taste resembles that of butter; and its specific gravity is intermediate between that of alkohol and water. It fuses at 58° C. and is not decomposed till the temperature be raised much above that of boiling water. It then affords oil, water, carbonic acid, and carburetted hydrogen, but no trace of ammonia. It is very soluble in alkohol, sulphuric and acetic æther, in the volatile oils of lavender, rosemary, turpentine, bergamot, &c. It is, on the other hand, insoluble in the fixed oils of olives, sweet almonds, and castor oil. It is equally so in the vegetable acids, and almost entirely insoluble in water, which takes up merely enough to make it redden litmus. Both in the cold, and with heat, nitric acid dissolves without altering it. Concentrated sulphuric acid acting on it for a considerable time, only carbonizes it.

It appears that the cholesteric acid is capable of uniting with the greater part of the salifiable bases. All the resulting salts are coloured, some yellow, others orange, and others red. The cholesterates of potassa, soda, ammonia, and probably of morphia, are very soluble and deliquescent; almost all the others are insoluble, or nearly so. There is none of them which cannot be decomposed by all the mineral acids, except the carbonic, and by the greater part of the vegetable acids; so that on pouring one of these acids into a solution of the cholesterate, the cholesteric acid is instantly separated in flocks. The soluble cholesterates form precipitates in all the metallic solutions, whose base has the property of forming an insoluble or slightly soluble salt with cholesteric acid.

Pelletier and Caventou found the cholesterate of barytes to consist of 100 of acid, and 56.259 base; whence the prime equivalent of the former appears to be about 17.35. Yet they observed, on the other hand, that on treating the cholesterate of lead with sulphuric acid, they obtained as much sulphate of lead as of cholesterate. From this experiment, the equivalent of the dry acid would seem to be 5; hence we may imagine, that when the cholesteric acid unites to the oxide of lead, and in general to all the oxides which have a slight affinity for oxygen, there takes place something similar to what happens in the reaction of oxide of lead and oxalic acid."—*Journ. de Phar.* iii. 292.

CHOLESTERINE. The name given by Chevreuil to the pearly substance of human biliary calculi. It consists of 72 carbon, 6.66 oxygen, and 21.33 hydrogen, by Berard.

CHOLICE'LE. (From χολη, bile, and χηλη, a tumour.) A swelling formed by the bile accumulated in the gall-bladder.

CHOLOLITHUS. (From χολη, bile, and λιθος, a stone, gall-stone.) A name of a genus of disease in the Class, *Cæliaca*; Order, *Splanchnica*, of Good's Nosology, characterised by pain about the region of the liver, catenating with pain at the pit of the stomach; the pulse unchanged; sickness; dyspepsy; inactivity; bilious concretion in the gall-bladder, or bile ducts. It has two species, *Chololithus quiescens*, the quiescent gall-stone, and *Cimeans*, the passing of gall-stones.

CHOLOLITHICUS. Of or belonging to gall-stone.

CHOLO'MA. (From χωλος, lame, or maimed.) 1. A halting, or lameness in the leg.

2. Galen says that, in Hippocrates, it signifies any distortion of a limb.

CHONDRO. Some muscles have this word forming a part of their name, because they are connected with a particular cartilage.

CHONDROGLO'SSUS. (From χονδρον, a cartilage, and γλωσση, the tongue.) A muscle so named from its insertion, which is in the basis or cartilaginous part of the tongue. See *Hyoglossus*.

CHONDRO'LOGY. (*Chondrologia*; from χονδρος, a cartilage, and λογος, a discourse.) A discourse on cartilages.

CHONDRO-PHARYNGÆUS. (From χονδρος, a cartilage, and φαρυγξ, the upper part of the fauces.) A muscle so named because it rises in the cartilaginous part of the tongue, and is inserted in the pharynx.

CHO'NDROS. Χονδρος. 1. A cartilage.

2. A food of the ancients, the same as alica.

3. Any grumous concretion.

CHONDROSYNDE'SMUS. (From χονδρος, a cartilage, and συνδεω, to tie together.) A cartilaginous ligament.

CHO'NDRUS. A cartilage.

CHO'NE. Χωνη. The infundibulum.

CHO'RA. Χωρα. A region. Galen, in his book De Usu Partium, expresses by it particularly the cavities of the eyes; but, in others of his writings, he intimates by it any void space.

CHO'RDA. (From χορδη, which properly signifies an intestine, or gut, of which a chord may be made.) 1. A cord, or assemblage of fibres.

2. A tendon.

3. A painful tension of the penis in the venereal disease.

4. Sometimes the intestines are called chordæ.

CHORDA MAGNA. A name of the *tendo Achillis*.

CHORDA TYMPANI. A branch of the seventh pair of nerves. The portio dura of the seventh pair of nerves, having entered the tympanum, sends a small branch to the stapes, and another more considerable one, which runs across the tympanum from behind forwards, passes between the long leg of the incus and the handle of the malleus, then goes out at the same place where the tendon of the anterior muscle of the malleus enters. It is called chorda tympani, because it crosses the tympanum as a cord crosses the bottom of a drum. Dr. Monro thinks, that the chorda tympani is formed by the second branch of the fifth pair, as well as by the portio dura of the seventh.

Chorda tendinea. The tendinous and cord-like substances which connect the *carneæ columnæ* of the ventricles of the heart to the auricular valves.

Chorda willisii. The small fibres which cross the sinuses of the dura mater. They are so termed, because Willis first described them.

Chorda′psus. (From *χορδη*, a cord, and *απτω*, to knit.) A sort of painful colic, where the intestines appear to be twisted into knots.

CHORDEE′. (*Chordé.* French.) A spasmodic contraction of the penis, that sometimes attends gonorrhœa, and is often followed by a hæmorrhage.

CHO′REA. (*Χορεια*; from *χορος*, a chorus, which of old accompanied dancing. It is called St. Vitus's dance, because some devotees of St. Vitus exercised themselves so long in dancing, that their interlects were disordered, and could only be restored by dancing again at the anniversary of St. Vitus.) *Chorea Sancti Viti. Synclonus chorea* of Good. St. Vitus's dance. Convulsive motions of the limbs, as if the person were dancing. It is a genus of disease, arranged by Cullen in the class *Neuroses;* and order *Spasmi.* These convulsive motions, most generally, are confined to one side, and affect principally the arm and leg. When any motion is attempted to be made, various fibres of other muscles act which ought not; and thus a contrary effect is produced from what the patient intended. It is chiefly incident to young persons of both sexes, and makes its attack between the age of ten and fifteen, occurring but seldom after that of puberty.

By some practitioners it has been considered rather as a paralytic affection than as a convulsive disorder, and has been thought to arise from a relaxation of the muscles, which, being unable to perform their functions in moving the limbs, shake them irregularly by jerks. Chorea Sancti Viti is occasioned by various irritations, as teething, worms, offensive smells, poisons, &c. It arises likewise in consequence of violent affections of the mind, as horror, fear, and anger. In many cases it is produced by general weakness; and, in a few, it takes place from sympathy, at seeing the disease in others.

The fits are sometimes preceded by a coldness of the feet and limbs, or a kind of tingling sensation, that ascends like cold air up the spine, and there is a flatulent pain in the left hypochondrium, with obstinate costiveness. At other times, the accession begins with yawning, stretching, anxiety about the heart, palpitations, nausea, difficulty of swallowing, noise in the ears, giddiness, and pains in the head and teeth; and then come on the convulsive motions.

These discover themselves at first by a kind of lameness, or instability of one of the legs, which the person draws after him in an odd and ridiculous manner; nor can he hold the arm of the same side still for a moment: for if he lays it on his breast, or any other part of his body, it is forced quickly from thence by an involuntary motion. If he is desirous of drinking, he uses many singular gesticulations before he can carry the cup to his head, and it is forced in various directions, till at length he gets it to his mouth; when he pours the liquor down his throat in great haste, as if he meant to afford amusement to the bystanders. Sometimes various attempts at running and leaping take place, and at others, the head and trunk of the body are affected with convulsive motions. In many instances, the mind is affected with some degree of fatuity, and often shows the same causeless emotions (such as weeping and laughing) which occur in hysteria. When this disease arises in children, it usually ceases about the age of puberty; and in adults, is often carried off by a change from the former mode of living. Unless it passes into some other disease, such as epilepsy, it is hardly attended with danger.

The leading indications in the treatment of this complaint are, 1. To obviate the several exciting causes; 2. To correct any faulty state of the constitution, which may appear to give a predisposition; 3. To use those means, which experience has shown best calculated to allay irregular muscular action. Among the sources of irritation, the most common is the state of the bowels; and the steady, but moderate, use of active cathartics has often a great effect upon the disease, improving the appetite and strength at the same time. Senna, scammony, jalap, &c. may be exhibited according to circumstances, often in conjunction with calomel, particularly where the liver is torpid. The general debility usually attending indicates the employment of tonics, as the cinchona, chalybeates, or sulphate of zinc, which is particulary useful; and with these cold bathing, not too long continued, may be advantageously conjoined; also requiring the patient to use muscular exertion, as much as they can readily, will assist materially in the cure. Sometimes in violent cases, and in irritable constitutions, the occasional exhibition of opium, or other sedative, may be required, taking care, however, that the bowels are not confined thereby. Occasionally too, where the above means are not successful, the more powerful antispasmodics may be tried, as æther, camphor, musk, &c. Electricity also has been by some recommended.

CHO′RION. (From *χωρεω*, to escape: because it always escapes from the uterus with the fœtus.) Shaggy chorion. The external membrane of the fœtus in utero.

CHO′ROID. (*Choroidea;* from *χοριον*, the chorion, and *ειδος*, resemblance.) Resembling the chorion, a membrane of the fœtal ovum.

Choroid membrane. *Membrana choroides.* The second tunic of the eye, lying immediately under the sclerotica, to which it is connected by vessels. The true knowledge of this membrane is necessary to a perfect idea of the iris and uvea. The tunica choroidea commences at the optic nerve, and passes forwards, with the sclerotic coat, to the beginning of the cornea transparens, where it adheres very firmly to the sclerotic membrane, by means of a cellular membrane, in the form of a white fringe, called the *ciliary circle.* It then recedes from the sclerotica and cornea and ciliary circle, directly downwards and inwards, forming a round disk, which is variously coloured; hence, blue, black eyes, &c. This coloured portion, reflected inwards, is termed the *iris*, and its posterior surface is termed *uvea.* The choroid membrane is highly vascular, and its external vessels are disposed like stars, and termed *vasa vorticosa.* The internal surface of this membrane is covered with a black pigment, called the pigment of the choroid membrane.

Choroid plexus. *Plexus choroideus.* A plexus of blood vessels, situated in the lateral ventricles of the brain.

Choroid tunic. See *Choroid membrane.*

Chri′sis. (From *χριω*, to anoint.) An inunction, or anointing of any part.

Christmas rose. See *Helleborus niger.*

Chris′tum. (From *χριω*, to anoint.) An unguent, or ointment of any kind.

CHRO'MAS. A chromate, or salt, formed by the union of chromic acid, with salifiable bases; as chromate of lead, &c.

CHROMATI'SMUS. (From χρωματιζω, to colour.) The morbid discoloration of any of the secretions, as of the urine, or blood.

CHRO'MIC ACID. *Acidum chromicum.* "This acid was extracted from the red lead ore of Siberia, by treating this ore with carbonate of potassa, and separating the alkali by means of a more powerful acid. In this state it is a red or orange-coloured powder, of a peculiar rough metallic taste, which is more sensible in it than in any other metallic acid. If this powder be exposed to the action of light and heat, it loses its acidity, and is converted into green oxide of chrome, giving out pure oxygen gas. The chromic acid is the first that has been found to de-oxygenate itself easily by the action of heat, and afford oxygen gas by this simple operation. It appears that several of its properties are owing to the weak adhesion of a part at least of its oxygen. The green oxide of chrome cannot be brought back to the state of an acid, unless its oxygen be restored by treating it with some other acid.

The chromic acid is soluble in *water*, and crystallises, by cooling and evaporation, in longish prisms of a ruby red. Its taste is acrid and styptic. Its specific gravity is not exactly known; but it always exceeds that of water. It powerfully reddens the tincture of turnsole.

Its action on *combustible substances* is little known. If it be strongly heated with charcoal, it grows black, and passes to the metallic state without melting.

Of the *acids*, the action of the muriatic on it is the most remarkable. If this be distilled with the chromic acid, by a gentle heat, it is readily converted into chlorine. It likewise imparts to it by mixture the property of dissolving gold; in which the chromic resembles the nitric acid. This is owing to the weak adhesion of its oxygen, and it is the only one of the metallic acids that possesses this property.

The extraction of chromic acid from the French ore, is performed by igniting it with its own weight of nitre in a crucible. The residue is lixiviated with water, which being then filtered, contains the chromate of potassa. On pouring into this a little nitric acid and muriate of barytes, an instantaneous precipitate of the chromate of barytes takes place. After having procured a certain quantity of this salt, it must be put in its moist state into a capsule, and dissolved in the smallest possible quantity of weak nitric acid. The barytes is to be then precipitated by very dilute sulphuric acid, taking care not to add an excess of it. When the liquid is found by trial to contain neither sulphuric acid nor barytes, it must be filtered. It now consists of water, with nitric and chromic acids. The whole is to be evaporated to dryness, conducting the heat at the end so as not to endanger the decomposition of the chromic acid, which will remain in the capsule under the form of a reddish matter. It must be kept in a glass phial well corked.

Chromic acid, heated with a powerful acid, becomes *chromic oxide;* while the latter, heated with the hydrate of an alkali, becomes chromic acid. As the solution of the oxide is green, and that of the acid yellow, these transmutations become very remarkable to the eye. From Berzelius's experiments on the combinations of the chromic acid with barytes, and oxide of lead, its prime equivalent seems to be 6.5; consisting of 3.5 chromium, and 3.0 oxygen.

It readily unites with *alkalies*, and is the only acid that has the property of colouring its salts, whence the name of chromic has been given it. If two parts of the red lead ore of Siberia in fine powder be boiled with one of an alkali saturated with carbonic acid, in forty parts of water, a carbonate of lead will be precipitated, and the *chromate* remain dissolved. The solutions are of a lemon colour, and afford crystals of a somewhat deeper hue. Those of *chromate of ammonia* are in yellow laminæ, having the metallic lustre of gold.

The *chromate of barytes* is very little soluble, and that of lime still less. They are both of a pale yellow, and when heated give out oxygen gas, as do the alkaline chromates.

If the chromic acid be mixed with filings of tin and the muriatic acid, it becomes at first yellowish-brown, and afterwards assumes a bluish-green colour, which preserves the same shade after desiccation. Æther alone gives it the same dark colour. With a solution of nitrate of mercury, it gives a precipitate of a dark cinnabar colour. With a solution of nitrate of silver, it gives a precipitate, which, the moment it is formed, appears of a beautiful carmine colour, but becomes purple by exposure to the light. This combination, exposed to the heat of the blowpipe, melts before the charcoal is inflamed, and assumes a blackish and metallic appearance. If it be then pulverized, the powder is still purple; but after the blue flame of the lamp is brought into contact with this powder, it assumes a green colour, and the silver appears in globules disseminated through its substance.

With nitrate of copper it gives a chesnut-red precipitate. With the solution of sulphate of zinc, muriate of bismuth, muriate of antimony, nitrate of nickel, and muriate of platina, it produces yellowish precipitates, when the solutions do not contain an excess of acid. With muriate of gold it produces a greenish precipitate.

When melted with borax, or glass, or acid of phosphorus, it communicates to it a beautiful emerald-green colour.

If paper be impregnated with it, and exposed to the sun a few days, it acquires a green colour, which remains permanent in the dark.

A slip of iron, or tin, put into its solution, imparts to it the same colour.

The aqueous solution of tannin produces a flocculent precipitate of a brown fawn colour.

Sulphuric acid, when cold, produces no effect on it; but when warm it makes it assume a bluish-green colour."—*Ure's Dict.*

CHROMIUM. (*Chromium, ii.* n.; from χρωμα, colour: because it is remarkable for giving colour to its combinations.) The name of a metal which may be extracted either from the native chromate of lead or of iron. The latter being cheapest and most abundant, is usually employed.

The brown chromate of iron is not acted upon by nitric acid, but most readily by nitrate of potassa, with the aid of a red heat. A chromate of potassa, soluble in water, is thus formed. The iron oxide thrown out of combination may be removed from the residual part of the ore by a short digestion in dilute muriatic acid. A second fusion with ¼ of nitre, will give rise to a new portion of chromate of potassa. Having decomposed the whole of the ore, we saturate the alkaline excess with nitric acid, evaporate and crystallise. The pure crystals, dissolved in water, are to be added to a solution of neutral nitrate of mercury; whence, by complex affinity, red chromate of mercury precipitates. Moderate ignition expels the mercury from the chromate, and the remaining chromic acid may be reduced to the metallic state, by being exposed in contact of the charcoal from sugar, to a violent heat.

Chromium thus procured, is a porous mass of agglutinated grains. It is very brittle, and of a greyish-white, intermediate between tin and steel. It is sometimes obtained in needleform crystals, which cross each other in all directions. Its sp. gravity is 5.9. It is susceptible of a feeble magnetism. It resists all the acids except nitromuriatic, which, at a boiling heat, oxidises it and forms a muriate. Thenard describes only one oxide of chromium; but there are probably two, besides the acid already described.

1. The *protoxide* is green, infusible, indecomposable by heat, reducible by voltaic electricity, and not acted on by oxygen or air. When heated to dull redness with the half of its weight of potassium or sodium, it forms a brown matter, which, cooled and exposed to the air, burns with flame, and is transformed into chromate of potassa or soda, of a canary-yellow colour. It is this oxide which is obtained by calcining the chromate of mercury in a small earthen retort for about ¾ of an hour. The beak of the retort is to be surrounded with a tube of wet linen, and plunged into water, to facilitate the condensation of the mercury. The oxide, newly precipitated from acids, has a dark-green colour, and is easily redissolved; but exposure to a dull red heat ignites it, and renders it denser, insoluble, and of a light green colour. This change arises solely from the closer aggregation of the particles, for the weight is not altered.

2. The *deutoxide* is procured by exposing the protonitrate to heat, till the fumes of nitrous gas cease to issue. A brilliant brown powder, insoluble in acids, and scarcely soluble in alkalies, remains. Muriatic acid digested on it exhales chlorine, showing the increased proportion of oxygen in this oxide.

3. The *tritoxide* has been already described among the acids. It may be directly procured, by adding nitrate of lead to the above nitrochromate of potassa, and digesting the beautiful orange precipitate of chromate of lead with moderately strong muriatic acid, till its power of action be exhausted. The fluid produced is to be passed through a filter, and a little oxide of silver very gradually added, till the whole solution becomes of a deep red tint. This liquor, by slow evaporation, deposits small ruby-red crystals, which are the hydrated chromic acid. The prime equivalent of chromic acid deduced from the chromates of barytes and lead by Berzelius, is 6.544, if we suppose them to be neutral salts. According to this chemist, the acid contains double the oxygen that the green oxide does. But if these chromates be regarded as subsalts, then the acid prime would be 13.088, consisting of 6 oxygen = 7.088 metal; while the protoxide would consist of 3 oxygen + 7.088 metal; and the deutoxide of an intermediate proportion.

CHRO′NIC. (*Chronicus*; from χρονος, time.) A term applied to diseases which are of long continuance, and mostly without fever. It is used in opposition to the term acute. See *Acute*.

CHRU′PSIA. (From χροα, colour, and οψις, sight.) *Visus coloratus.* A disease of the eyes, in which the person perceives objects of a different colour from their natural one.

CHRYSA′NTHEMUM. (From χρυσος, gold, and ανθεμον, a flower.) 1. The name of a genus of plants in the Linnæan system. Class, *Syngenesia*; Order, *Polygamia*. Sun-flower, or marigold.

2. Many herbs are so called, the flowers of which are of a bright yellow colour.

CHRYSANTHEMUM LEUCANTHEMUM. The systematic name of the great ox-eye daisy. Maudlin-wort. *Bellis-major; Buphthalmum majus; Leucanthemum vulgare; Bellidioides; Consolida media; Oculus bovis.* The *Chrysanthemum;—foliis amplexicaulibus, oblongis, supernè serratis, infernè dentatis,* of Linnæus. The flowers and herb were formerly esteemed in asthmatic and phthisical diseases, but have now deservedly fallen into disuse.

CHRY′SE. (From χρυσος, gold.) The name of a yellow plaster.

CHRYSELE′CTRUM. (From χρυσος, gold, and ηλεκτρον, amber.) Amber, of a golden yellow colour.

CHRYSI′PPEA. (From *Chrysippus*, its discoverer.) An herb enumerated by Pliny.

CHRYSI′TIS. (From χρυσος, gold.) 1. Litharge.

2. The yellow foam of lead.

3. The herb yarrow, from the golden colour of its flower.

CHRYSOBA′LANUS. (From χρυσος, gold, and βαλανος, a nut; so named because of its colour, which, before it is dried, is yellow.) The nutmeg.

CHRYSOBERYL. Cymophane of Haüy. A mineral of an asparagus green colour and vitreous lustre, found in the Brazil, and Ceylon.

CHRYSOCO′LLA. (From χρυσος, gold, and κολλη, cement.) Gold solder; Borax.

CHRYSO′COMA. (From χρυσος, gold, and κομη, hair; so called from its golden, hair-like appearance.) The herb milfoil, or yarrow. See *Achillea millefolium.*

CHRYSOGO′NIA. (From χρυσος, gold, and γινομαι, to become.) A tincture of gold.

CHRYSOLA′CHANON. (From χρυσος, gold, and λαχανον, a pot-herb; so named from its having a yellow leaf.) The herb orach; a species of atriplex.

CHRYSOLITE. (Peridot of Haüy. Topaz of the ancients, while our topaz is their chrysolite. The hardest of all gems of a pistachio-green colour. It comes from Egypt and Bohemia.

CHRYSOSPLE′NIUM. (From χρυσος, gold, and ασπλενιον, spleenwort.) The name of a genus of plants in the Linnæan system. Class, *Decandria*; Order, *Digynia*. Golden saxifrage.

CHRYSOPRASE. A variety of calcedony.

CHRYSU′LCUS. (From χρυσος, gold, and ελκω, to take away.) The aqua regia which has the property of dissolving gold.

CHUSITE. A yellowish-green translucent mineral, found by Saussure in the cavities of porphyries, in the environs of Limbourg.

CHYAZIC ACID. See *Prussic acid.*

CHYLA′RIA. (From χυλος, chyle.) A discharge of a whitish mucous urine, of the colour and consistence of chyle.

CHYLE. *Chylus.* The milk-like liquor observed some hours after eating, in the lacteal vessels of the mesentery, and in the thoracic duct. It is separated by digestion from the chyme, and is that fluid substance from which the blood is formed. See *Digestion.*

"The chyle may be studied under two different forms:

1st, When it is mixed with chyme in the small intestine.

2d, Under the liquid form, circulating in the chyliferous vessels, and the thoracic duct.

No person having particularly engaged in the examination of the chyle during its stay in the small intestine, our knowledge on this point is little. The liquid chyle contained in the chyliferous vessels has been examined with great care.

In order to procure it, the best manner consists in giving food to an animal, and, when the digestion is supposed to be in full activity, to strangle it, or cut the spinal marrow behind the occipital bone. The whole length of the breast is cut open; the hand is thrust in so as to pass a ligature which embraces the aorta, the œsophagus, and the thoracic duct, the nearest to the neck possible; the ribs of the left side are then twisted or broken, and the thoracic duct is seen, closely adhering to the œsophagus. The upper part is detached, and carefully wiped to absorb the blood; it is cut, and the chyle flows into the vessel intended to receive it.

The ancients were acquainted with the existence of the chyle, but their ideas of it were very inexact: it was observed anew at the beginning of the seventeenth century; and being, in certain conditions, of an opaque white, it was compared to milk: the vessels that contain it were even named *lacteal vessels*, a very improper expression, since there is very little other similarity between chyle and milk except the colour.

It is only in modern times, and by the labours of Dupuytren, Vauquelin, Emmert, and Marcet, that positive notions concerning the chyle have been acquired.

We shall give the observations of these learned men, with the addition of our own.

If the animal from which the chyle is extracted has eaten animal or vegetable substances of a fatty nature, the liquid drawn from the thoracic duct is of a milky white, a little heavier than distilled water, of a strong spermatic odour, of a salt taste, slightly adhering to the tongue, and sensibly alcaline.

Chyle, very soon after it has passed out of the vessel that contained it, becomes firm, and almost solid: after some time it separates into three parts; the one solid that remains at the bottom, another liquid at the top, and a third that forms a very thin layer at the surface of the liquids. The chyle, at the same time, assumes a vivid rose colour.

When the chyle proceeds from food that contains no fat substance, it presents the same sort of properties, but instead of being opaque white, it is opaline, and almost transparent; the layer which forms at the top is less marked than in the former sort of chyle.

Chyle never takes the hue of the colouring substances mixed in the food, as many authors have pretended.

Animals that were made to eat indigo, saffron, and madder, furnished a chyle the colour of which had no relation to that of the substances.

Of the three substances into which the chyle separates when abandoned to itself, that of the surface, of an opaque white colour, is a fatty body; the solid part is formed of fibrin and a little colouring matter; the liquid is like the serum of the blood.

The proportion of these three parts is variable according to the nature of the food. There are species, of chyle, such as that of sugar, which contain very little fibrin; others, such as that of flesh, contain more. The same thing happens with the fat matter, which is very abundant when the food contains grease or oil, whilst there is scarcely any seen when the food is nearly deprived of fatty bodies.

The absorption of the chyle has been attributed to the capillarity of the lacteal radicles, to the compression of the chyle by the sides of the small intestine, &c. Latterly it has been pretended that it takes place by virtue of the proper sensibility of the absorbing mouths, and of the insensible organic contractility that they are supposed to possess. It first enters the threads of the lacteal vessels, it then traverses the mesenteric glands, it arrives at the thoracic duct, and at last enters the subclavian vein.

The causes that determine its motion are the contractility proper to the chyliferous vessels, the unknown cause of its absorption, the pressure of the abdominal muscles, particularly in the motions of respiration, and, perhaps, the pulsation of the arteries of the abdomen.

If we wish to have a correct idea of the velocity with which the chyle flows into the thoracic duct, we must open this canal in a living animal, at the place where it opens into the subclavian vein. We find that this rapidity is not very great, and that it increases every time that the animal compresses the viscera of the abdomen, by the abdominal muscles; a similar effect is produced by compressing the belly with the hand.

However, the rapidity of the circulation of the chyle appears to me to be in proportion to the quantity formed in the small intestine; this last is in proportion to the quantity of the chyme: so that if the food is in great abundance, and of easy digestion, the chyle will flow quickly; if, on the contrary, the food is in small quantity, or, which is the same thing, if it is of difficult digestion, as less chyle will be formed, so its progress will be more slow.

It would be difficult to appreciate the quantity of chyle that would be formed during a given digestion, though it ought to be considerable. In a dog of ordinary size that had eaten animal food at discretion, an incision into the thoracic duct of of the neck (the dog being alive) gave about half an ounce of liquid in five minutes, and the running was not suspended during the whole continuance of the formation of the chyle, that is, during several hours.

It is not known whether there is any variation in the rapidity of the motion of the chyle during the same digestion; but supposing it uniform, there would enter six ounces of chyle per hour into the venous system. We may presume that the proportion of chyle is more considerable in man, whose chyliferous organs are more voluminous, and in whom the digestion is, in general, more rapid than in the dog." *Magendie's Phisiology.*

The chyle is mixed with the albuminous and gelatinous lymph in the thoracic duct, which receives them from the lymphatics.

The uses of the chyle are, 1. To supply the matter from which the blood and other fluids of our body are prepared; from which fluids the solid parts are formed. 2. By its acescent nature, it somewhat restrains the putrescent tendency of the blood: hence the dreadful putridity of the humours from starving; and thus milk is an excellent remedy against scurvy. 3. By its very copious aqueous latex, it prevents the thickening of the fluids, and thus renders them fit for the various secretions. 4. The chyle secreted in the breasts of puerperal women, under the name of milk, forms the most excellent nutriment of all aliments for new-born infants.

CHYLIFICA'TION. (*Chylificatio;* from *chylus*, and *fio*, to become.) *Chylifactio.* The process carried on in the small intestines, and principally in the duodenum, by which the chyle is separated from the chyme.

CHYLI′SMA. (From χυλος, juice.) An expressed juice.

CHYLOPOIE′TIC. (*Chylopoieticus;* from χυλος, chyle, and ποιεω, to make.) Chylopoietic. Any thing connected with the formation of chyle; thus chylopoietic viscera, chylopoietic vessels, &c.

CHYLO′SIS. (From χυλος, juice.) Chylification, or the changing the food into chyle.

CHYLOSTA′GMA. (From χυλος, juice, and ςαζω, to distil.) The distillation or expression of any juice, or humid part from the rest.

CHYLOSTAGMA DIAPHORETICUM. A name given by Mindererus to a distillation of Venice treacle and mithridate.

CHYLUS. (Χυλος, *succus,* from χυω, juice.) See *Chyle.*

CHYME. (*Chymus;* from χυμος, which signifies humour or juice.) The ingested mass of food that passes from the stomach into the duodenum, and from which the chyle is prepared in the small intestines by the admixture of the bile, &c. See *Digestion.*

CHY′MIA. Chemistry.

CHYMIA′TER. A chemical physician.

CHYMIA′TRIA. (From χυμια, chemistry, and ιαομαι, to heal.) The art of curing diseases by the application of chemistry to the uses of medicine.

CHYMO′SIS. See *Chemosis.*

CHY′NLEN RADIX. A cylindrical root of the thickness of a goose-quill, brought from China. It has a bitterish taste, and imparts a yellow tinge to the saliva. The Chinese hold it in great estimation as a stomachic, infused in wine.

CHY′SIS. (From χυω, to pour out.) Fusion, or the reduction of solid bodies into fluid by heat.

CHY′TLON. (From χυω, to pour out.) An anointing with oil and water.

CIBA′LIS. (From *cibus,* food.) Of or belonging to food.

CIBALIS FISTULA. An obsolete term for the œsophagus.

CIBA′TIO. (From *cibus,* food.) The taking of food.

CI′BUR. An obsolete term for sulphur.

CICATRISANT. (*Cicatrisans;* from *cicatrico,* to skin over.) Such applications as dispose wounds and ulcers to dry up and heal, and to be covered with a skin.

CICA′TRIX. (From *cicatrico,* to heal up or skin over.) A seam or scar upon the skin after the healing of a sore or ulcer.

Cicely, sweet. See *Scandix odorata.*

CI′CER. (A plant so called. The *Cicerones* had their name from this pulse, as the *Pisones* had from the pisum or pea, and the *Lentuli* from the lens or lentil.) 1. The name of a genus of plants in the Linnæan system. Class, *Diadelphia;* Order, *Decandria.* The vetch.

2. The pharmacopœial name of the common cich or ciches.

CICER ARIETINUM. The systematic name of the *cicer* plant. *Erebinthus; Cicer—foliis serratis,* of Linnæus. The seeds have been employed medicinally, but are now fallen into disuse. In some places they are toasted, and used as coffee; and in others, ground into a flour for bread. The colour of the arillus of the seed is sometimes white, red, or black; hence the distinction into *cicer album, rubrum,* and *nigrum.*

CI′CERA. (From *cicer,* the vetch.) A small pill of the size of a vetch.

CICERA TARTARI. Small pills composed of turpentine and cream of tartar, of the size of a vetch.

CICHO′RIUM. (Originally, according to Pliny, an Egyptian name, and adopted by the Greeks. It is written sometimes Κιχορειον: whence Horace has *cichoreæ, levesque malvæ:* sometimes Κιχοριον, or Κιχωριον. It is supposed by some to have this name, παρα το δια των χωριων κιειν, from its creeping through the fields. Others derive it from κιχεω, *invenio;* on account of its being so readily found, or so common.) Succory. 1. The name of a genus of plants in the Linnæan system. Class, *Syngenesia,* Order, *Polygamia æqualis.*

2. The pharmacopœial name of the wild cichory. See *Cichorium intybus.*

CICHORIUM ENDIVIA. The systematic name of the endive. *Endivia; Endiva; Cichorium;—floribus solitariis, penduncula*tis, *foliis integris; crenatis,* of Linnæus, is an extremely wholesome salad, possessing bitter and anodyne qualities.

CICHORIUM INTYBUS. The systematic name of the wild succory. *Cichorium; Cichoreum; Cichorium sylvestre vel officinarum, Cichorium;—floribus geminis, sessilibus; foliis runcinatis,* of Linnæus. It belongs to the same family with the garden endive, and by some botanists has been supposed to be the same plant in its uncultivated state; but the endive commonly used as salad is an annual, or at most a biennial plant, and its parent is now known to be the *cichorium endivia.* Wild succory or cichory, abounds with a milky juice, of a penetrating bitterish taste, and of no remarkable smell, or particular flavour: the roots are more bitter than the leaves or stalks, and these much more so than the flowers. By culture in gardens, and by blanching, it loses its bitterness, and may be eaten early in the spring in salads. The roots, if gathered before the stem shoots up, are also eatable, and when dried may be made into bread. The roots and leaves of this plant are stated by Lewis to be very useful aperients, acting mildly and without irritation, tending rather to abate than to increase heat, and which may therefore be given with safety in hectic and inflammatory cases. Taken freely, they keep the belly open, or produce a gentle diarrhœa; and when thus continued for some time, they have often proved salutary in the beginning obstructions of the viscera, in jaundices, cachexies, hypochondriacal and other chronical disorders. A decoction of this herb, with others of the like kind, in whey, and rendered purgative by a suitable addition of polychrest salt, was found an useful remedy in cases of biliary calculi, and promises advantage in many complaints requiring what have been termed attenuants and resolvents. The virtues of succory, like those of dandelion, reside in its milky juice; and we are warranted, says Dr. Woodville, in asserting, that the expressed juice of both these plants, taken in large doses frequently repeated, has been found an efficacious remedy in phthisis pulmonalis, as well as the various other affections above-mentioned. The milky juice may be extracted by boiling in water, or by pressure. The wild and the garden sorts are used indifferently. If the root is cut into small pieces, dried, and roasted, it resembles coffee, and is sometimes a good substitute for it.

CI′CHORY. See *Cichorium intybus.*

Cichory, wild. See *Cichorium intybus.*

CICINDE′LA. (A dim. of *candela:* i. e. a little candle; so called from its light.) The glow-worm. By some thought to be anodyne, lithontriptic, though probably neither. Not used in the present day.

CICI′NUM OLEUM. (From κικι, the ricinus.)

An oil, obtained by boiling the bruised seeds of the *Jatropha curcas* of Linnæus. It is somewhat similar in its properties to castor oil.

CI′CLA. A name for the white beet.

CICU′TA. (*Quasi cæcuta*, blind; because it destroys the sight of those who use it. Cicuta signifies also the internode, or space between two joints of a reed; or the hollow stem of any plant which the shepherds used for making their rural pipes. *Est mihi disparibus septem conjuncta cicutis fistula.* Virgil.) Hemlock. 1. The name of a genus of plants in the Linnæan system. Class, *Pentandria*; Order, *Digynia*.

2. The name, in most pharmacopœias, of the common hemlock. See *Conium*.

CICUTA AQUATICA. See *Cicuta virosa*.

CICUTA VIROSA. The systematic name of the *Cicuta aquatica*; *Cicutaria virosa*; *Sium majus alterum angustifolium*; *Sium erucæ folio*; long-leaved water hemlock and cow-bane. This plant, *Cicuta—umbellis oppositifoliis; petiolis marginatis obtusis*, of Linnæus, is seldom employed medicinally in the present day. It is an active poison, and often eaten by mistake for the wild smallage, the *Apium graveolens*, of Linnæus; when it produces tremors, vertigo, a violent burning at the stomach, epilepsy, convulsions, spasms of the jaw, a flowing of blood from the ears, tumefaction of the abdomen, and death.

CICUTA′RIA. (From *cicuta*, hemlock.) Bastard hemlock. See *Chærophyllum sylvestre*.

CICUTARIA AQUATICA. See *Phellandrium aquaticum*.

CICUTARIA VIROSA. See *Cicuta virosa*.

CIDO′NIUM. See *Pyrus cydonia*.

CILIA. (The plural of *cilium*.) A species of pubescence of plants which consists of hairs on the margin of a leaf or petal, giving it a fringed appearance.

CI′LIAR. (*Ciliaris*; from *cilium*, the eyelid.) Belonging to the eyelid.

CILIAR LIGAMENT. *Ligamentum ciliare.* The circular portion that divides the choroid membrane from the iris, and which adheres to the sclerotic membrane. It appears like a white circular ring. See *Choroid membrane*.

CILIARE LIGAMENTUM. See *Choroid membrane*.

CILIARIS MUSCULUS. That part of the musculus orbicularis palpebrarum which lies nearest the cilia, considered by Riolan as a distinct muscle.

CILIATUS. Bordered, fringed: applied to leaves, corolla, petals, &c.: hence *folium ciliatum*, *anthodium ciliatum*, and *petala ciliata*. See *Leaf*, *Corolla*, *Anthodium*, *Petalum*.

CI′LIUM. (From *cilleo*, to move about.) The eyelid or eyelash. See also *Cilia*.

CILIARY PROCESSES. The white folds at the margin of the uvea in the eye, covered with a black matter, which proceed from the uvea to the crystalline lens, upon which they lie.

CI′LLO. (From *cilium*, the eyelid.) One who is affected with a spasm or trembling of the eyelids.

CILLO′SIS. (From *cilium*, the eyelid.) A spasmodic trembling of the eyelids.

Cimeter-shaped. See *Leaf*.

CIMEX. (From κειμαι, to inhabit; so called because they infest houses.) The name of a genus of insects in the Linnæan system. The wall-louse or bug.

CIMEX DOMESTICUS. Six or seven are given inwardly to cure the ague, just before the fits come on, and have the same effect with every thing nauseous and disgusting.

CIMO′LIA ALBA. (From Κιμωλος, Cimolus, an island in the Cretan sea, where it is procured.) See *Cimolite*.

CIMOLIA PURPURESCENS. Fullers-earth.

CIMOLITE. Cimolian earth. The *Cimolia* of Pliny. An earth of a greyish white colour, which consists of silex, alumina, oxide of iron and water.

CI′NA CINÆ. See *Cinchona*.

CI′NÆ SEMEN. See *Artemisia santonica*.

CI′NARA. (From κινεω, to move; *quasi movet ad venerem vel urinam.*) Artichoke. 1. The name of a genus of plants in the Linnæan system. Class, *Syngenesia*; Order, *Polygamia æqualis*.

2. The pharmacopœial name for the common artichoke. See *Cinara scolymus*.

CINARA SCOLYMUS. The systematic name of the artichoke, called in the pharmacopœias *Alcocalum*; *Agriocinara*; *Articocalus*; *Artischocas lævis*; *Costus nigra*; *Carduus sativus non spinosus*; *Cinara hortensis*; *Scolymus sativus*; *Carduus domesticus capite majore*; *Carduus altilis*. The *Cinara—foliis subspinosis pinnatis indivisique calycinis squamis ovatis*, of Linnæus. A native of the southern parts of Europe, but cultivated here for culinary purposes. The leaves are bitter, and afford, by expression, a considerable quantity of juice, which, when strained, and mixed with an equal quantity of white wine, has been given successfully in dropsies, in the dose of 3 or 4 table-spoonfuls night and morning, but it is very uncertain in its operation.

CINCHO′NA. (Geoffroy states that the use of this bark was first learned from the following circumstance:—Some cinchona trees being thrown by the winds into a pool of water, lay there till the water became so bitter, that every body refused to drink it. However, one of the neighbouring inhabitants being seized with a violent paroxysm of fever, and finding no other water to quench his thirst, was forced to drink of this, by which he was perfectly cured. He afterwards related the circumstance to others, and prevailed upon some of his friends, who were ill of fevers, to make use of the same remedy, with whom it proved equally successful. The use of this excellent remedy, however, was very little known till about the year 1638, when a signal cure having been performed by it on the Spanish viceroy's lady, the Countess del Cinchon, at Lima, it came into general use, and hence it was distinguished by the appellation of *cortex cinchonæ*, and *pulvis comitissæ*, or the Countess's powder. On the recovery of the Countess, she distributed a large quantity of the bark to the Jesuits, in whose hands it acquired still greater reputation, and by them it was first introduced into Europe, and thence called *cortex*, or *pulvis jesuiticus*, *pulvis patrum*; and also Cardinal del Lugo's powder, because that charitable prelate bought a large quantity of it at great expence for the use of the religious poor at Rome.) 1. The name of a genus of plants in the Linnæan system. Class, *Pentandria*; Order, *Monogynia*. Cinchona, or Peruvian bark-tree.

2. The pharmacopœial name of several kinds of barks; called also *Cortex*. *Cortex china*; *China*; *Chinchina*; *Kina kina*, *Kinkina*; *Quina quina*, *Quinquina*; the trees affording which, grow wild in the hilly parts of Peru; the bark is stripped from the branches, trunk and root, and dried. Three kinds of it are now in use.

1. *Cortex cinchonæ cordifoliæ.*—The plant which affords this species is the *Cinchona cor-*

difolia of Zea; the *Cinchona officinalis*, of Linnæus; the *Cinchona macrocarpa*, of Willdenow. Heart-leaved cinchona. The bark of this tree is called *yellow bark*, because it approaches more to that colour than either of the others does. It is in flat pieces, not convoluted like the pale, nor dark-coloured like the red; externally smooth, internally of a light cinnamon colour, friable and fibrous; has no peculiar odour different from the others, but a taste incomparably more bitter, with some degree of astringency.

2. *Cortex cinchonæ lancifoliæ.*—This species is obtained from the *Cinchona lancifolia* of Zea. Lance-leaved cinchona. This is the *quilled bark*, which comes in small quilled twigs, breaking close and smooth, friable between the teeth, covered with a rough coat of a brownish colour, internally smooth, and of a light brown; its taste is bitter, and slightly astringent; flavour slightly aromatic, with some degree of mustiness.

3. *Cortex cinchonæ oblongifolia.*—This kind is procured from *Cinchona oblongifolia* of Zea. Oblong-leaved cinchona. This is the *red bark*: it is in large thick pieces, externally covered with a brown rugged coat, internally more smooth and compact, but fibrous, of a dark red colour; taste and smell similar to that of the *cinchonæ lancifoliæ cortex*, but the taste rather stronger.

From the general analysis of bark, it appears to consist, besides the woody matter which composes the greater part of it, of gum, resin, gallic acid, of very small portions of tannin and essential oil, and of several salts having principally lime for their basis. Seguin also supposed the existence of gelatin in it, but without sufficient proof. Cold water infused on pale bark for some hours, acquires a bitter taste, with some share of its odour; when assisted by a moderate heat, the water takes up more of the active matter; by decoction, a fluid, deep coloured, of a bitter styptic taste, is obtained, which, when cold, deposits a precipitate of resinous matter and gallic acid. By long decoction, the virtues of the bark are nearly destroyed, owing to the oxygenation of its active matter. Magnesia enables water to dissolve a larger portion of the principles of bark, as does lime, though in an inferior degree. Alkohol is the most powerful solvent of its active matter. Brandy and other spirits and wines, afford also strong solutions, in proportion to the quantity of alkohol they contain. A saturated solution of ammonia is also a powerful solvent; vinegar is less so even than water. By distillation, water is slightly impregnated with the flavour of bark; it is doubtful whether any essential oil can be obtained.

The action of menstrua on the red bark is nearly the same, the solutions only being considerably stronger, or containing a larger quantity of resinous matter, and of the astringent principle.

The analysis of the yellow bark, shows that its active principles are more concentrated than in either of the others, affording to water, alkohol, &c. tinctures, much stronger both in bitterness, and astringency, especially in the former principle.

Vauquelin made infusions of all the varieties of cinchona he could procure, using the same quantities of the barks and water, and leaving the powders infused for the same time. He observed, 1. That certain infusions were precipitated abundantly by infusion of galls, by solution of glue and tartar emetic. 2. That some were precipitated by glue, but not by the two other reagents; and, 3. That others were, on the contrary by nutgalls, and tartar emetic, without being affected by glue. 4. And that there were some which yielded no precipitate by nutgalls, tannin, or emetic tartar. The cinchonas that furnished the first infusion were of excellent quality; those that afforded the fourth were not febrifuge; while those that gave the second and third were febrifuge, but in a smaller degree than the first. Besides mucilage, kinate of lime, and woody fibre, he obtained in his analyses a resinous substance, which appears not to be identic in all the species of bark. It is very bitter, very soluble in alkohol, in acids, and alkalies; scarcely soluble in cold water, but more soluble in hot. It is this body which gives to infusions of cinchona the property of yielding precipitates by emetic tartar, galls, gelatin; and in it the febrifuge virtue seems to reside. It is this substance in part which falls down on cooling decoctions of cinchona, and from concentrated infusions. A table of precipitations by glue, tannin, and tartar emetic, from infusions of different barks, has been given by Vauquelin.

Pelletier and Caventou analysed the *Cinchona condaminæa*, grey bark, and found it composed of, 1. cinchonina, united to kinic acid; 2. green fatty matter; 3. red colouring matter, slightly soluble; 4 tannin; 5. yellow colouring matter; 6. kinite of lime; 7. gum; 8. starch; 9. lignine.

The red bark has been considered as superior to the pale, the yellow is represented, apparently with justice, as being more active than either of the others.

The effects of Peruvian bark, are those of a powerful and permanent tonic, so slow in its operation, that its stimulating property is scarcely perceptible by any alteration in the state of the pulse, or of the temperature of the body. In a large dose, it occasions nausea and headache; in some habits it operates as a laxative; in others it occasions costiveness. It is one of those medicines, the efficacy of which, in removing disease, is much greater than could be expected, *à priori*, from its effects on the system in a healthy state.

Intermittent fever is the disease, for the cure of which bark was introduced into practice, and there is still no remedy which equals it in power. The disputes respecting the mode of administering it are now settled. It is given as early as possible, after clearing the stomach and bowels, in the dose of from one scruple to a drachm every second or third hour, during the interval of the paroxysm; and it may even be given during the hot fit, but it is then more apt to excite nausea.

In remittent fever it is given with equal freedom, even though the remission of the fever may be obscure.

In some forms of continued fever which are connected with debility, as in typhus, cynanche maligna, confluent small-pox, &c. it is regarded as one of the most valuable remedies. It may be prejudicial, however, in those diseases where the brain, or its membranes are inflamed, or where there is much irritation, marked by subsultus tendinum, and convulsive motions of the extremities; and in pure typhus it appears to be less useful in the beginning of the disease than in the convalescent stage.

Even in fevers of an opposite type, where there are marks of inflammatory action, particularly in acute rheumatism, bark has been found useful after blood-letting. In erysipelas, in gangrene, in extensive suppuration and venereal ulceration, the free use of bark is of the greatest advantage.

In the various forms of passive hæmorrhagy, in many other diseases of chronic debility, dyspepsia, hypochondriasis paralysis, rickets, scrofula, dropsy, and in a variety of spasmodic affections, epilepsy, chorea, and hysteria it is administered as a powerful and permanent tonic, either alone, or combined with other remedies suited to the particular case.

The officinal preparations of bark are an infusion, decoction, an extract, a resinous extract, a simple tincture, an ammoniated and a compound tincture. The usual dose is half a drachm of the powder. The only inconvenience of a larger dose is its sitting uneasy on the stomach. It may therefore, if necessary, be frequently repeated, and in urgent cases may be taken to the extent of an ounce, or even two ounces in twenty-four hours.

The powder is more effectual than any of the preparations; it is given in wine, in any spirituous liquor; or, if it excite nausea, combined with an aromatic. The cold infusion is the least powerful, but most grateful; the decoction contains much more of the active matter of the bark, and is the preparation generally used when the powder is rejected; its dose is from two to four ounces. The spirituous tincture, though containing still more of the bark, cannot be extensively used on account of the menstruum, but is principally employed, occasionally, and in small doses of two or three drachms, as a stomachic. The extract is a preparation of considerable power, when properly prepared, and is adapted to those cases where the remedy requires to be continued for some time. It is then given in the form of pill, in doses of from five to fifteen grains.

Bark is likewise sometimes given in the form of enema; one scruple of the extract, or two drachms of the powder, being diffused in four ounces of starch mucilage. The decoction is also sometimes applied as a fomentation to ulcers.

CINCHONA CARIBÆA. The systematic name of the Caribæan bark-tree. It grows in Jamaica, where it is called the sea-side beech. According to Dr. Wright, the bark of this tree is not less efficacious than that of the cinchona of Peru, for which it will prove an useful substitute; but by the experiments of Dr. Skeete, it appears to have less astringent power.

CINCHONA CONDAMINŒA. See *Cinchona* and *Cinchonina.*

CINCHONA CORDIFOLIA. See *Cinchona.*

CINCHONA FLAVA. See *Cinchona.*

CINCHONA FLORIBUNDA. The systematic name of the plant which affords the Saint Lucé bark. *Cinchona—floribus paniculatis glabris, capsulis turbinatis lævibus, foliis ellipticis acuminatis glabris*, of Linnæus. It has an adstringent, bitter taste, somewhat like gentian. It is recommended in intermittents, putrid dysentery, and dyspepsia: it should always be joined with some aromatic. Dr. Withering considers this bark as greatly inferior to that of the other species of this genus. In its recent state it is considerably emetic and cathartic, properties which in some degree it retains on being dried; so that the stomach does not bear this bark in large doses, and in small ones its effects are not such as to give it any peculiar recommendation.

CINCHONA LANCIFOLIA. See *Cinchona.*

CINCHONA OBLONGIFOLIA. See *Cinchona.*

CINCHONA OFFICINALIS. The name of the officinal Peruvian bark. See *Cinchona.*

CINCHONA RUBRA. See *Cinchona.*

CINCHONA SANCTA FE′. Several species of cinchona have been lately discovered at Sancta Fé, yielding barks both of the pale and red kind; and which, from their sensible qualities, are likely upon trial to become equally useful with those produced in the kingdom of Peru.

CINCHONIA. See *Cinchonina.*

CINCHONINA. *Cinchonia; Quinia; Quinina.* Cinchonine or Quinine is the salifiable base, or vegetable alkali, discovered in the Cinchona condaminœa, by Pelletier and Caventou. The person however, who first recognized its existence, though he did not ascertain its alkaline nature, or study its combinations with acids, was Gornis of Lisbon.

The following process for extracting cinchonina is that of Henry, the younger, which the above chemists approve. A kilogramme of bark reduced into a fine powder, is to be acted on twice with heat, by a dilute sulphuric acid, consisting of 50 or 60 grammes, diluted with 8 kilogrammes of water for each time. The filtered decoctions are very bitter, have a reddish colour, which assumes on cooling a yellowish tint. To discolour (blanch) these liquors, and saturate the acid, either pulverized quicklime or magnesia may be employed. The liquors, entirely deprived of colour, are to be passed through a cloth, and the precipitate which forms is to be washed with a small quantity of water, to separate the excess of lime (if this earth has been used.) The deposit on the cloth, well drained and almost completely deprived of moisture for twelve hours, after having been put three successive times to digest in alkohol of 36° (0.837,) will furnish, by distilling of the liquid alkohol, a brown viscid matter, becoming brittle on cooling. It is to be acted on with water sharpened with sulphuric acid, and the refrigerated liquor will afford about thirty grammes of white crystals, entirely soluble in alkohol, scarcely soluble in cold water, but more in boiling water, particularly if this be slightly acidulated. They consist of pure sulphate of cinchonina. They ought to be brilliant, crystallised in parallelopipeds, very hard, and of a glassy-white. It should burn without leaving any residuum. Other processes have been given, of which a full account will be found in the 12th volume of the Journal of Science, p. 325. From a solution of the above salt, the cinchonina may be easily obtained by the addition of any alkali. The cinchonina falls down, and may be afterwards dissolved in alkohol, and crystallised by evaporation. Its form is a rhomboidal prism, of 108° and 72°, terminated by a bevelment. It has but little taste, requiring 7000 parts of water for its solution; but when dissolved in alkohol, or an acid, it has the bitter taste of bark. When heated it does not fuse before decomposition. It consists of oxygen, hydrogen, and carbon, the latter being predominant. It dissolves in only very small quantities in the oils, and in sulphuric ether.

The sulphate is composed of cinchonina	100
Sulphuric acid - - -	13

whence the prime equivalent would appear to be 38.5. The muriate is more soluble. It consists of

Cinchonina - -	100
Muriatic acid - -	7.9

The nitrate is uncrystallisable. Gallic, oxalic, and tartaric acids, form neutral salts with cinchonina, which are soluble only with excess of acid. Hence infusion of nut-galls gives, with a decoction of good cinchona, an abundant precipitate of gallate of cinchonina.

Robiquet gives as the composition of a subsulphate of cinchonina of the first crystallisation.

Sulphuric acid - - -	11.3
Cinchonina - - -	79.0

The alkaline base found in yellow barks is called *Quinina.* It is extracted in exactly the same way. Red bark contains a mixture of these two alkalies. The febrifuge virtue of the sulphates is considered to be very great.

CINCI′NNUS. The hair on the temples.

CINCLE'SIS. (From κιγκλιζω, to move.) *Cinclismus.* An involuntary nictitation or winking. *Vogel.*

CINERA'RIUM. (From *cinis*, ashes.) The ash-hole of a chemical instrument.

CI'NERES. (Plural of *cinis*, ashes.) Ashes.

CINERES CLAVELLATA. See *Potassa impura.*

CINERES RUSSICI. See *Potassa impura.*

CINERI'TIOUS. (*Cineritius*; from *cinis*, ashes.) Of the colour of ashes. A name applied to the cortical substance of the brain, from its resemblance to an ash-colour.

CINERI'TIUM. (From *cinis*, ashes.) A cupel or test; so named from its being commonly made of the ashes of vegetables or bones.

CINE'RULAM. A name for spodium.

CINETICA. (Κινητικος, having the power of motion.) The name of an order in the class *Neuroses* of Good's Nosology. Diseases affecting the muscles, and embracing *Entasia, Clonus*, and *Synclonus.*

CINE'TUS. The diaphragm.

CINGULA'RIA. (From *cingulum*, a girdle; because it grows in that shape.) The lycopodium.

CI'NGULUM. (From *cingo*, to bind.) A girdle or belt about the loins.

CINGULUM MERCURIALE. A mercurial girdle, called also *cingulum sapientiæ*, and *singulum stultitiæ*. It was an invention of Rulandus's: different directions are given for making it, but the following is one of the neatest:—"Take three drachms of quicksilver; shake it with two ounces of lemon-juice until the globules disappear; then separate the juice, and mix with the extinguished quicksilver, half the white of an egg; gum-dragon, finely powdered, a scruple; and spread the whole on a belt of flannel."

CINGULUM SANCTI JOHANNIS. A name of the artemisia.

CINIFICA'TUM. A name for calcinatum.

CINIS. (*Cinis, eris.* m., in the plural *cineres.*) The ash which remains after burning any thing.

CI'NNABAR. (*Cinnabaris, ris.* f. Pliny says the Indians call by this name a mixture of the blood of the dragon and elephant, and also many substances which resemble it in colour, particularly the minium; but it now denotes the red sulphuret of mercury.)

1. An ore of mercury, consisting of that mineral united to sulphur. A native sulphuret of mercury. See *Hydrargyri sulphuretum rubrum.*

2. An artificial compound of mercury and sulphur, called factitious cinnabar, red sulphuret of mercury, and vermilion. See *Hydrargyri sulphuretum rubrum.*

CINNABARIS FACTITIA. Factitious cinnabar. See *Hydrargyri sulphuretum rubrum.*

CINNABARIS GRÆCORUM. The sanguis draconis and cinnabar.

CINNABARIS NATIVA. Native cinnabar. See *Hydrargyri sulphuretum rubrum.*

CINNAMO'MUM. (From *kinamon*, Arabian.) Cinnamon. See *Laurus cinnamomum.*

CINNAMON. 1. The name of a tree. See *Laurus cinnamomum.*

2. The name of a stone, which is a rare mineral found in the sand of rivers in Ceylon, of a blood and hyacinth red, passing into orange yellow.

CINQUEFOIL. See *Potentilla reptans.*

CI'ON. (Κιων, a column; from κιω, to go.)

1. The uvula was formerly so named from its pyramidal shape.

2. An enlargement of the uvula.

CIO'NIS. (From κιων, the uvula.) An enlargement and painful swelling of the uvula.

CIPOLIN. A marble from Rome and Autun.

CIRCÆ'A. (From *Circe*, the enchantress: so named from the opinion, that it was used by Circe in her enchanted preparations.) 1. The name of a genus of plants in the Linnæan system. Class, *Diandria;* Order, *Monogynia.* Enchanter's nightshade.

2. The name in some pharmacopœias for the *Circæa lutetiana*, which is now fallen wholly into disuse.

CIRCOCE'LE. (Κιρσοκηλη; from κιρσος, *varix*, or a dilatation of a vein, and κηλη, a tumour.) *Varicocele.* A morbid or varicose distention and enlargement of the spermatic veins; it is frequently mistaken for a descent of a small portion of omentum. The uneasiness which it occasions is a kind of pain in the back, generally relieved by suspension of the scrotum; and whether considered on account of the pain, or on account of the wasting of the testicle, which now and then follows, it may truly be called a disease. It has been resembled to a collection of earthworms. It is most frequently confined to that part of the spermatic process, which is below the opening in the abdominal tendon; and the vessels generally become rather larger as they approach the testes. There is one sure method of distinguishing between a circocele and omental hernia; place the patient in an horizontal posture, and empty the swelling by pressure upon the scrotum; then put the fingers firmly upon the upper part of the abdominal ring, and desire the patient to rise; if it is a hernia, the tumour cannot re-appear, as long as the pressure is continued at the ring: but if a circocele, the swelling returns with increased size, on account of the return of blood into the abdomen being prevented by the pressure.

CI'RCOS. (From κιρκος, a circle.) A ring. It is sometimes used for the sphincter muscle which is round like a ring.

CIRCULA'TION. (*Circulatio*; from *circulo*, to compass about.) *Circulatio sanguinis.* Circulation of the blood. A vital action performed by the heart in the following manner: the blood is returned by the descending and ascending venæ cavæ into the right auricle of the heart, which, when distended, contracts, and sends its blood into the right ventricle; from the right ventricle it is propelled through the pulmonary artery to circulate through, and undergo a change in the lungs, being prevented from returning into the right auricle by the closing of the valves, which are situated there for that purpose. Having undergone this change in the lungs, it is brought to the left auricle of the heart by the four pulmonary veins, and from thence it is evacuated into the left ventricle. The left ventricle, when distended, contracts and throws the blood through the aorta to every part of the body, to be returned by the veins into the two venæ cavæ. It is prevented from passing back from the left ventricle into the auricle by a valvular apparatus; and the pulmonary artery and aorta at their origin are also furnished with similar organs, to prevent its returning into the ventricles. This is a brief outline of the circulation, the particulars of which we shall now describe.

"The best informed physiologists avow that the circulation of the venous blood is still very little understood. We shall describe here only its most apparent phenomena, leaving the most delicate questions until we treat of the relation of the flowing of the blood in the veins, with that in the arteries. We will then speak of the cause that determines the entrance of the blood into the venous radicles.

To have a general, but just idea of the course of the blood in the veins, we must consider that the sum of the small veins forms a cavity much larger than that of the larger but less numerous veins, into which they pass; that these bear the same relation to the trunks in which *they* terminate: consequently, the blood which flows in the veins from branches towards the trunks, passes always from a larger to a smaller cavity; now, the following principle of hydro-dynamics may here be perfectly applied:

When a liquid flows in a tube which it fills completely, the quantity of this liquid which traverses the different sections of the tube in a given time ought to be every where the same: consequently, when the tube increases, the velocity diminishes: when the tube diminishes, the velocity increases in rapidity.

Experience confirms this principle, and its just application to the current of venous blood. If a very small vein is cut, the blood flows from it very slowly; it flows quicker from a larger vein, and it flows with considerable rapidity from an open venous trunk.

Generally there are several veins to transport the blood that has traversed an organ towards the larger trunks. On account of their anastomoses, the compressure or ligature of one or several of these veins does not prevent or diminish the quantity of blood that returns to the heart; it merely acquires a greater rapidity in the veins which remain free.

This happens when a ligature is placed on the arm for the purpose of bleeding. In the ordinary state, the blood, which is carried to the fore-arm and the hand, returns to the heart by four deep veins, and at least as many superficial ones; but as soon as the ligature is tightened, the blood passes no longer by the subcutaneous veins, and it traverses with difficulty those which are deeper seated. If one of the veins is then opened at the bend of the arm, it passes out in form of a continued jet, which continues as long as the ligature remains firm, and stops as soon as it is removed.

Except in particular cases, the veins are not much distended by the blood; however, those in which it moves with the greatest rapidity are much more so: the small veins are scarcely distended at all. For a reason very easy to be understood, all the circumstances that accelerate the rapidity of the blood in a vein, produce also an augmentation in the distention of the vessel.

The introduction of blood into the veins taking place in a continued manner, every cause which arrests its course produces distention of the vein, and the stagnation of a greater or less quantity of blood in its cavity, below the obstacle.

The sides of the veins seem to have but a small influence upon the motion of the blood; they easily give way when the quantity augments, and return to their usual form when it diminishes; but their contraction is limited; it is not sufficiently strong to expel the blood completely from the vein, and therefore those of dead bodies always contain some.

A great number of veins, such as those of the bones, of the sinuses of the *dura mater*, of the testicles, of the liver, &c., the sides of which adhere to an inflexible canal, can have evidently no influence upon the motion of the blood that flows in their cavity.

However, it is to the elasticity of the sides of the veins, and not to a contraction similar to that of the muscles that we must attribute the faculty which they possess of diminishing the size when the column of blood diminishes: this diminution is also much more marked in those that have the thickest sides, such as the superficial veins.

If the veins themselves have very little influence upon the motion of the blood, many other accessary causes exert a very evident effect. Every continued or alternate pressure upon a vein, when strong enough to flatten it, may prevent the passage of the blood; if it is not so strong, it will oppose the dilatation of the vein by the blood, and consequently favour its motion. The constant pressure which the skin of the members exert upon the veins that are below it, renders the flow of the blood more easy and rapid in these vessels. We cannot doubt this, for all the circumstances that diminish the contractility of the tissue of the skin, are sooner or later followed by a considerable dilatation of the veins, and in certain cases by varix; we know also that mechanical compression, exerted by a proper bandage, reduces the veins again to their ordinary dimensions, and also regulates the motion of the blood within them.

In the abdomen, the veins are subject to the alternate pressure of the diaphragm, and of the abdominal muscles, and this cause is equally favourable to the flow of the venous blood in this part.

The veins of the brain support also a considerable pressure, which must produce the same result.

Whenever the blood runs in the direction of its weight, it flows with greater facility; the contrary takes place when it flows against the direction of its gravity.

We must not neglect to notice the relations of these accessory causes with the disposition of the veins. Where they are very marked, the veins present no valves, and their sides are very thin, as is seen in the abdomen, the chest, the cavity of the skull, &c.; where these have less influence, the veins present valves, and have thicker sides; lastly, where they are very weak, as in the subcutaneous veins, the valves are numerous, and the sides have a considerable thickness.

We must take care, however, not to confound among the circumstances favourable to the motion of the blood in the veins, causes which act in another manner.

For example, it is generally known that the contraction of the muscles of the fore-arm and the hand, during bleeding, accelerate the motion of the blood which passes through the opening of the vein; physiologists say that the contraction of the muscles compresses the deep veins, and expels the blood from them, which then passes into the superficial veins. Were it thus, the acceleration would be only instantaneous, or at least of short duration, while it generally continues as long as the contraction. We shall see, farther on, how this phenomenon ought to be explained.

When the feet are plunged some time in hot water, the subcutaneous veins swell, which is generally attributed to the rarefaction of the blood; though the true cause is the augmentation of the quantity of blood in the feet, but particularly at the skin, an augmentation which ought naturally to accelerate the motion of the blood in the veins, since they are in a given time traversed by a greater quantity of blood.

After what has preceded, we can easily suppose that the venous blood must be frequently stopped or hindered in its course, either by the veins suffering too strong a pressure in the different positions of the body, or by other bodies pressing upon it, &c.: hence the necessity of the numerous anastomoses that exist not only in the small veins, but among the large, and even among the largest trunks. By these frequent communications, one or several of the veins being compressed in such a way, that they cannot permit the passage of the blood, this fluid turns and arrives at the heart by other directions:—one of the uses of the azygos vein appears to be to establish an easy communication between the superior and inferior vena cava. Its principal utility, however, seems to consist in its being the common termination of most of the intercostal veins.

There is no obscurity in the action of the valves of the veins; they are real valves, which prevent the return of the blood towards the venous radicles, and which do this so much better in proportion as they are large, that is to say, more suitably disposed to stop entirely the cavity of the vein.

The friction of the blood against the sides of the veins; its adhesion to the sesame sides, and the want of fluidity, must modify the motion of the blood in the veins, and tend to retard it; but in the present state of physiology and hydrodynamics, it is impossible to assign the precise effect of each of these particular causes.

We ought to perceive, by what has been said upon the motion of the venous blood, that it must undergo great modifications, according to an infinity of circumstances.

At any rate, the venous blood of every part of the body arrives at the right auricle of the heart by the trunks that we have already named; viz. two very large, the venæ cavæ, and one very small, the coronary vein.

The blood probably flows in each of these veins with different rapidity: what is certain, is, that the three columns of liquid make an effort to pass into the auricle, and that the effort must be considerable. If it is contracted, this effort has no effect; but as soon as it dilates, the blood enters its cavity, fills it completely, and even distends the sides a little; it would immediately enter the ventricle, if it did not contract itself at this instant. The blood then confines itself to filling up exactly the cavity of the auricle; but this very soon contracts, compresses the blood, which escapes into the place where there is least compression. Now it has only two issues: 1st, by the vena cava; 2dly, by the opening which conducts into the ventricle. The columns of blood which are coming to the auricle present a certain resistance to its passage into the cavæ or coronary veins. On the contrary, it finds every facility to enter the ventricle, since the latter dilates itself with force, tends to produce a vacuum, and consequently draws on the blood instead of repulsing it.

However, all the blood that passes out of the auricle does not enter the ventricle; it has been long observed that, at each contraction of the auricle, a certain quantity of blood flows back into the superior and inferior venæ cavæ; the undulation produced by this cause is sometimes felt as far as the external iliac veins, and into the jugulars; it has a sensible influence, as we will see, upon the flowing of the blood in several organs, and particularly in the brain.

The quantity of blood which flows back in this manner, varies according to the facility with which this liquid enters the ventricle. If, at the instant of its dilatation, the ventricle still contains much blood, which has not passed into the pulmonary artery, it can only receive a small quantity of that of the auricle, and then the reflux will be of greater extent.

This happens when the flowing of the blood in the pulmonary artery is retarded, either by obstacles in the lungs, or by the want of sufficient force in the ventricle. This reflux, of which we speak, is the cause of the beating which is seen in the veins of certain sick persons, and which bears the name of *venous pulse.* Nothing similar can take place in the coronary vein, for its opening is furnished with a valve, which shuts on the instant of the contraction of the auricle.

The instant in which the auricle ceases to contract, the ventricle enters into contraction, the blood it contains is strongly pressed, and tends to escape in every direction: it would return so much more easily into the auricle, that, as we have already frequently said, it dilates just at this instant; but the tricuspid valve which shuts the *auriculo-ventricular* opening prevents this reflux. Being raised by the liquid introduced below it, and which tends to pass into the auricle, it gives way until it has become perpendicular to the axis of the ventricle; its three divisions then shut almost completely the opening, and as the tendons of the *columnæ carneæ* do not permit them to go farther, the valve resists the effort of the blood, and thus prevents it from passing into the auricle.

It is not the same with the blood which during the dilatation of the ventricle corresponded to the auricular surface of the valve; it is evident that in the motion of the ventricle it is carried forward into the auricle, where it mixes with that which comes from the *venæ cavæ* and coronary veins.

Not being able to overcome the resistance of the tricuspid valve, the blood of the ventricle has no other issue than the pulmonary artery, into which it enters by raising the three sigmoid valves that supported the column of blood contained in the artery during the dilatation of the ventricle.

Suppose the artery full of blood, and left to itself, the liquid will be pressed in the whole extent of the vessel by the sides which tend to contract upon the cavity; the blood being thus pressed will endeavour to escape in every direction: now it has only two ways to pass, by the cardiac orifice, and by the numerous small vessels that terminate the artery in the tissue of the lungs.

The orifice of the pulmonary artery in the heart being very large, the blood would easily pass into the ventricle, if there were not a particular apparatus at this orifice intended to prevent this; the three sigmoid valves. Being pressed against the sides of the artery, at the instant that the ventricle sends a wave of blood that way, these folds become perpendicular to its axis; as soon as the blood tends to flow back into the ventricle, they place themselves so as to shut up the cavity of this vessel completely.

On account of the bag-like form of the sigmoid valves, they are swelled by the blood that enters into their cavity, and their margin tends to assume a circular figure. Now, three circular portions, placed upon each other, necessarily leave a space between them.

When the valves, therefore, of the pulmonary artery are lowered by the blood, there ought to remain an opening by which this liquid may flow back into the ventricle.

If each valve were alone, it would undoubtedly take a semicircular form; but there are three of them: being pressed by the blood, they lie all close together: and as they cannot extend as far as their fibres permit them, they press upon each other, on account of the small space in which they are contained, and which does not permit their extending themselves. The valves then assume the figure of three triangles, whose summit is in the centre of the artery, and the sides are in *juxta position*, so as completely to intercept the cavity of the artery. Perhaps the *knots* or *buttons*, which are upon the summit of some of the triangles, are intended to shut more perfectly the centre of the artery.

Finding no passage into the ventricle, the blood will pass into the radicles of the pulmonary veins, with which the small arteries that terminate the pulmonary artery form a continuation, and this passage will continue as long as the sides of the artery press the contained blood with sufficient force; and, except in the trunk and the principal branches, this effect continues until the whole of the blood is expelled.

We might suppose the smallness of the vessels that terminate the pulmonary artery an obstacle to the flowing of the blood: that might be if they were not numerous, or if the capacity of the whole were less, or even equal to that of the trunk; but as they are innumerable, and their capacity is much greater than that of the trunk, there is no difficulty in the motion. It is true that the distension or subsidence of the lungs, renders this passage more or less easy.

In order that this flowing may take place with facility, the force of contraction of the different divisions of the artery ought to be every where in relation to their size; if, on the contrary, that of the small were greater than that of the large, as soon as the first had expelled the blood by which they were filled, they would not be sufficiently distended by the blood coming from the second, and the flowing of the blood would be retarded: now, what takes place is quite the contrary of this supposition. If the pulmonary artery of a living animal were tied immediately above the heart, almost all the blood contained in the artery at the instant of the ligature, would pass quickly into the pulmonary veins, and arrive at the heart.

This is what happens when the blood contained in the pulmonary artery is exposed to the single action of this vessel; but in the common state at each contraction of the right ventricle, a certain quantity of blood is thrown with force into the artery; the valves are immediately raised; the artery, and almost all its divisions, are so much more distended, in proportion as the heart is more forcibly contracted, and as the quantity of blood injected into the artery is greater. The ventricle dilates immediately after its contraction, and at this instant the sides of the artery contract also; the sigmoid valves descend and shut the pulmonary artery, until they are raised by a new contraction of the ventricle.

Such is the second cause of the motion of the blood in the artery that goes towards the lungs; we see it is intermittent; let us endeavour to appreciate its effects: for which purpose let us consider the most apparent phenomena of the flow of the blood in the pulmonary artery.

It has been just observed, that in the instant the ventricle injects the blood into the artery, the trunk, and all the divisions of a certain size, undergo an evident dilatation. This phenomenon is called the *pulsation* of the artery. The pulsation is very sensible near the heart; it becomes feeble in proportion to its distance from it; when the artery, by being divided, has become very small, it ceases.

Another phenomenon, which is only the consequence of the preceding, is observed when the artery is opened.

If it be near the heart, and in a place where the beating is sensible, the blood spouts out by jerks; if the opening be made far from the heart, and in a small division, the jet is continued and uniform; lastly, if one of the very small vessels that terminate the artery be opened, the blood flows, but without forming any jet: it flows uniformly in a sheet.

We see at first in these phenomena a new application of the principle of hydro-dynamics, as already mentioned, with regard to the influence of the size of the tube upon the liquid that flows in it: the greater the tube is, the rapidity is the less. This capacity of the vessel increasing according as it advances towards the lungs, the quickness of the blood necessarily diminishes.

With regard to the pulsation of the artery, and the jet of blood that escapes from it when it is open, we see plainly that these two effects depend on the contraction of the right ventricle, and the introduction of a certain quantity of blood into the artery, which takes place by this means while flowing through the small vessels that terminate the artery, and that give commencement to the pulmonary veins; the venous blood changes its nature by the effect of the contact of the air; it acquires the qualities of arterial blood: it is this change in the properties of the blood which essentially constitutes respiration.

At the instant in which the venous blood traverses the small vessels of the pulmonary lobules, it assumes a scarlet colour; its odour becomes stronger, and its taste more distinct, its temperature rises about a degree; a part of its serum disappears in the form of vapour in the tissue of the lobules, and mixes with the air. Its tendency to coagulate augments considerably, which is expressed by saying that its *plasticity* becomes stronger, its specific gravity diminishes, as well as its capacity for caloric. The venous blood, having acquired these characters, now becomes arterial blood, and enters the radicles of the pulmonary veins, which have their origin, like the veins properly so called, in the tissue of the lungs; that is, they form at first an infinite number of radicles, which appear to be the continuation of the pulmonary artery. These radicles unite to form thicker roots, which become still thicker. Lastly, they all terminate in four vessels, which open, after a short passage, into the left auricle. The pulmonary veins are different from the other veins, in their not anastomosing after they have acquired a certain thickness: a similar disposition has been seen in the divisions of the artery which is distributed to the lungs.

The pulmonary veins have no valves, and their structure is similar to that of the other veins; their middle membrane is, however, a little thicker, and it appears to possess more elasticity. The blood passes into the radicles of the pulmonary veins, and very soon reaches the trunk of these veins: in this passage it presents a gradually accelerated motion, in proportion as it passes from the small veins into the larger: finally, it does not at all flow by jerks, and it appears nearly equally rapid in the four pulmonary veins. From the pulmonary veins the left auricle receives the blood.

The mechanism by which the blood traverses the left auricle and ventricle is the same as that by which the venous blood traverses the right cavities.

When the left auricle dilates, the blood of the four pulmonary veins enters and fills it; when it contracts, part of the blood passes into the ventricle, and part flows back into the pulmonary veins; when the ventricle dilates, it receives the blood which comes from the auricle, and a small quantity of that of the *aorta;* when it contracts, the mitral valve is raised, it shuts the *auriculo-ventricular* opening, and the blood, not being able to return into the auricle, it enters into the aorta by raising the three sigmoid valves, which were shut during the dilatation of the ventricle.

It is necessary to remark, however, that the fleshy columns having no existence in the auricle, their influence cannot exist as in the right, and the arterial ventricle being much thicker than the venous, it compresses the blood with a much greater force than the right, which was indispensable on account of the distance to which it has to send this liquid.

Course of the blood in the aorta, and its divisions.—Notwithstanding the differences which exist between this and the pulmonary artery, the phenomena of the motion of the blood are nearly the same in both: thus a ligature being applied upon this vessel, near the heart, in a living animal, it contracts in its whole length, and, except a small quantity that remains in the principal arteries, the blood passes immediately into the veins.

Some authors doubt the fact of the contraction of the arteries; the following experiment may be made to convince them: uncover the carotid artery of a living animal the length of several inches; take the transverse dimension of the vessel with compasses, tie it at two different points at the same time, and you may then have any length whatever of artery full of blood; make a small opening in the sides of this portion of the artery, you will immediately see almost the whole of the blood pass out, and it will even spout to a certain distance. Then measure the breadth with the compasses, and there will be no doubt of the artery being much contracted, if the rapid expulsion of the blood has not already convinced you. This experiment also proves that the force with which the artery contracts is sufficient to expel the blood that it contains.

Passage of the blood of the arteries into the veins.—When, in the dead body, an injection is thrown into an artery, it immediately returns by the corresponding vein: the same thing takes place, and with still more facility, if the injection is thrown into the artery of a living animal. In cold-blooded animals, the blood can be seen, by the aid of a microscope, passing from the arteries into the veins. The communication between these vessels is then direct, and very easy; it is natural to suppose that the heart, after having forced the blood to the last arterial twigs, continues to make it move into the venous radicles, and even into the veins. Harvey, and a great number of celebrated anatomists, thought so. Lately, Bichât has been strongly against this doctrine: he has limited the influence of the blood; he pretends that it ceases entirely in the place where the arterial is changed into venous blood, that is, in the numerous small vessels that terminate the arteries and commence the veins. In this place, according to him, the *action of the small vessels alone* is the cause of the motion of the blood.

Remarks on the Movements of the Heart.—A. The right auricle and ventricle, and the left auricle and ventricle, the action of which we have studied separately, in reality form only one organ, which is the heart.

The auricles contract and dilate together; the same thing takes place with the ventricles, whose movements are simultaneous.

When the contraction of the heart is spoken of, that of the ventricle is understood. Their contraction is called *systole*, their dilatation *diastole*.

B. Every time that the ventricles contract, the whole of the heart is rapidly carried forward, and the point of this organ strikes the left lateral side of the chest, opposite the internal of the sixth and seventh true ribs.

C. The number of the pulsations of the heart is considerable; it is generally greater in proportion as the person is younger.

At birth it is from 130 to 140 in a minute.
At one year ...... 120 to 130.
At two years ...... 100 to 110.
At three years .... 90 to 100.
At seven years ... 85 to 90.
At fourteen years 80 to 85.
At adult age ...... 75 to 80.
At first old age ... 65 to 75.
At confirmed old age 60 to 65.

But these numbers vary according to an infinity of circumstances, sex, temperament, individual disposition, &c.

The affections of the mind have a great influence upon the rapidity of the contractions of the heart; every one knows that even a slight emotion immediately modifies the contractions, and generally accelerates them. In this respect great changes take place also by diseases.

D. Many researches have been made to determine with what force the ventricles contract. In order to appreciate that of the left ventricle, an experiment has been made, which consists in crossing the legs, and placing upon one knee the ham of the other leg, with a weight of 55 pounds appended to the extremity of the foot. This considerable weight, though placed at the extremity of such a long lever, is raised at each contraction of the ventricle, on account of the tendency to straighten the accidental curvature of the popliteal artery, when the legs are crossed in this manner.

This experiment shows that the force of contraction of the heart is very great; but it cannot give the exact value of it. Mechanical physiologists have made great efforts to express it in numbers. Borelli compares the force which keeps up the circulation to that which would be necessary to raise 180,000 pounds; Hales believes it to be 51 pounds 5 ounces; and Keil reduces it to from 15 to 8 ounces. Where shall we find the truth in these contradictions?

It seems impossible to know exactly the force developed by the heart in its contraction; it very probably varies according to numerous causes, such as age, the volume of the organ, the size of the individual; the particular disposition, the quantity of blood, the state of the nervous system, the action of the organs, the state of health or of sickness, &c.

All that has been said of the force of the heart relates only to its contraction, its dilatation having been considered as a passive state, a sort of repose of the fibres; however, when the ventricles dilate, it is with a very great force, for example, capable of raising a weight of twenty pounds, as may be observed in animals recently dead. When the heart of a living animal is taken hold of by the hand, however small it may be, it is impossible by any effort to prevent the dilatation of the ventricles. The dilatation of the heart, then, cannot be considered as a state of inaction or repose.

E. The heart moves from the first days of existence of the embryo to the instant of death by decrepitude.

Why does it move? This question has been asked by ancient and modern philosophers and physiologists. The *wherefore* of phenomena is not easy to be given in physiology; almost always what is taken for such is only in other terms the expression of the phenomena; but it is remarkable how easily we deceive ourselves in this respect: one of the strongest proofs of it is afforded by the different explanations of the motion of the heart.

The ancients said that there was a *pulsific virtue* in the heart, a *concentrated fire*, that gave motion to this organ. Descartes imagined that *an explosion as sudden as that of gunpowder* took place in the heart. The motion of the heart was afterwards attributed to the *animal spirits*, to the *nervous fluid*, to the *soul*, to the *process of the nervous system*, to the *archea:* Haller considered it as an effect of irritability. Lately, Legallois has endeavoured to prove, by experiments, that the principle or cause of the motion of the heart has its seat in the spinal marrow.

Remarks upon the circular Motion of the Blood, or the Circulation.—We now know all the links of the circular chain that the sanguiferous system represents: we know how the blood is carried from the lungs towards all the other parts of the body, and how it returns from these parts to the heart. Let us examine these phenomena in a general manner, in order to show the most important.

A. The quantity of blood contained in the system is very considerable. It has been estimated by several authors at from 24 to 30 pounds. This value cannot be at all exact, for the quantity of blood varies according to numerous causes.

The relation of the mass of the arterial with that of the venous blood, is somewhat better known. This last, contained in vessels larger than that of the arteries, is necessarily in greater quantity, though we cannot say exactly how much greater its mass is than that of the arterial blood.

B. The circulatory path of the blood being continuous, and the capacity of the canal variable, the rapidity of this fluid must be variable also; for the same quantity must pass through all the points in a given time: observation confirms this. The rapidity is great in the trunk, and the principal divisions of the pulmonary artery and aorta: it diminishes much in the secondary divisions; it diminishes still more at the instant of the passage from the arteries into the veins; it continues to augment in proportion as the blood passes from the roots of the veins into larger roots, and lastly into the large veins; but the rapidity is never so great in the venæ cavæ as in the aorta. In the trunks and the principal arterial divisions, the course of the blood is not only continued under the influence of the contraction of the arteries, but, besides, it flows in jerks by the effect of the contraction of the ventricles. This jerking manifests itself in the arteries by a simple dilatation in those that are straight, and by a dilatation and tendency to straighten in those which are flexuous.

The pulse is formed by the first of these phenomena, to which the second is sometimes joined. It is not easy to study, in man or in the animals, except where the arteries are laid close upon a bone, because they do not then retire from under the finger when it is placed upon them, as happens to arteries in soft parts.

In general, the pulse makes known the principal modification of the contraction of the left ventricle, its quickness, its intensity, its weakness, its regularity, its irregularity. The quantity of the blood is also known by the pulse. If it is great, the artery is round, thick, and resisting. If the blood is in small quantity, the artery is small and easily flattened. Certain dispositions in the arteries have an influence also upon the pulse, and may render it different in the principal arteries.

C. The beating of the arteries is necessarily felt in the organs which are next them, and so much more in proportion as the arteries are more voluminous, and as the organs give way with less facility. The jerk which they undergo is generally considered as favourable to their action, though no positive proof of it exists.

In this respect none of the organs ought to be more affected than the brain. The four cerebral arteries unite in circles at the base of the skull, and raise the brain at each contraction of the ventricle, as it is easy to be convinced of by laying bare the brain of an animal, or by observing this organ in wounds of the head. Probably, the numerous angular bendings of the internal carotid arteries, and of the vertebrals before their entrance into the skull, are useful for moderating this shaking; these bendings must also necessarily retard the course of the blood in these vessels.

When the arteries penetrate in a voluminous state into the parenchyma of the organs, as the liver, the kidneys, &c., the organ must also receive a jerk at each contraction of the heart. The organs into which the vessels enter, after being divided and subdivided, can suffer nothing similar.

D. From the lungs to the left auricle the blood is of the same nature; however, it sometimes happens that it is not the same in the four pulmonary veins. For instance, if the lungs are so changed that the air cannot penetrate into the lobules, the blood which traverses them will not be changed from venous to arterial blood; it will arrive at the heart without having undergone this change; but in its passage through the left cavities it will be intimately mixed with that of the lungs opposite. The blood is necessarily homogeneous from the left ventricle to the last divisions of the aorta; but, being arrived at these small divisions, its elements separate; at least there exists a great number of parts, such as the serous membranes, the cellular tissue, the tendons, the aponeuroses, the fibrous membranes, &c., into which the red part of the blood is never seen to penetrate, and the capillaries of which contain only serum.

This separation of the elements of the blood takes place only in a state of health; when the parts that I have mentioned become diseased, it often happens that their small vessels contain blood, possessed of all its characteristic properties.

There have been endeavours to explain this particular analysis of the blood by the small vessels. Boerhaave, who admitted several sorts of globules of different sizes in the blood, said, that globules of a certain largeness could only pass into vessels of an appropriate size: we have seen that globules, such as they were admitted by Boerhaave, do not exist.

Bichât believed that there existed in the small vessels a particular sensibility, by which they admitted only the part of the blood suitable to them. We have already frequently contested ideas of this kind; neither can they be admitted here, for the most irritating liquids introduced into the arteries pass immediately into the veins, without any opposition to their passage by the capillaries.

E. The elements of the blood separate in traversing the small vessels; sometimes the serum escapes, and spreads upon the surface of the membrane: sometimes the fatty matter is deposited in cells; here the mucus, there the fibrine; elsewhere are the foreign substances, which were accidentally mixed with the arterial blood. In losing these different elements, the blood assumes the qualities of venous blood. At the same time that the arterial blood supplies these losses, the small veins absorb the substances with which they are in contact. In the intestinal canal, for example, they absorb the drinks; on the other hand, the lymphatic trunks pour the lymph and the chyle into the venous system: it is certain, then, that the venous blood cannot be homogeneous, and that its composition must be variable in the different veins; but, having reached the heart, by the motions of the right auricle and ventricle, and the disposition of the fleshy columns, the elements all mix together, and when they are completely mixed, they pass into the pulmonary artery.

F. A general law of the economy is, that no organ continues to act without receiving arterial blood; from this results, that all the other functions are dependent on the circulation; but the circulation, in its turn, cannot continue without the respiration by which the arterial blood is formed, and without the action of the nervous system, which has a great influence upon the rapidity of the flowing of the blood, and upon its distribution in the organs. Indeed, under the action of the nervous system, the motions of the heart, and consequently the general quickness of the course of the blood, are quickened or retarded. Thus, when the organs act voluntarily or involuntarily, we learn from observation, that they receive a greater quantity of blood without the motion of the general circulation being accelerated on that account; and if their action predominates, the arteries which are directed there, increase considerably. If, on the contrary, the action diminishes, or ceases entirely, the arteries become smaller, and permit only a small quantity to reach the organ. These phenomena are manifest in the muscles: the circulation becomes more rapid in them when they contract; if they are often contracted, the volume of their arteries increases; if they are paralysed, the arteries become very small, and the pulse is scarcely felt.

The circulation, then, may be influenced by the nervous system in three ways: 1st, By modifying the motions of the heart; 2dly, By modifying the capillaries of the organs, so as to accelerate the flowing of the blood in them; 3dly, By producing the same effects in the lungs, that is, by rendering the course of the blood more or less easy through this organ.

The acceleration of the motions of the heart becomes sensible to us by the manner in which the point of this organ strikes the walls of the chest. The difficulty of the capillary circulation is discovered by a feeling of numbness and a particular prickling; and when the pulmonary circulation is difficult, we are informed of it by an oppression or sense of suffocation, more or less strong.

Probably the distribution of the filaments of the great sympathetic on the sides of the arteries, has some important use; but this use is entirely unknown; we have received no light on the point by any experiment."—*Magendie's Elements of Physiology.*

Circula'tor. (From *circulo*, to compass about.) A wandering practiser in medicine. A quack; a mountebank.

Circulato'rium. (From *circulo*, to move round.) A chemical digesting vessel in which the fluid performs a circulatory motion.

CIRCULUS. (Dim. of *circus*, a circle.) 1. A circle or ring.

2. Any part of the body which is round or annular, as *circulus oculi.*

3. A round chemical instrument sometimes called abbreviatorium by the old chemists.

Circulus arteriosus iridis. The artery which runs round the iris and forms a circle, is so termed.

Circulus quadruplex. A bandage.

Circumcaula'lis. A name of the adnata of the eye.

CIRCUMCI'SION. (*Circumcisio*, from *circumcido*, to cut about.) The cutting off the prepuce from the glans penis; an ancient custom, still practised among the Jews and rendered necessary by the heat of the climate in which it was first practised, to prevent collections and a vitiated state of the sebaceous secretion from the odoriferous glands of the part.

CIRCUMFLE'XUS. (*Circumflexus*, sc. *musculus.*) A muscle of the palate. *Tensor palati* of Innes. *Circumflexus palati mollis* of Albinus. *Spheno-salpingo-staphilinus, seu staphilinus externus* of Winslow. *Musculus tubæ novæ* of Valsalva. *Palato-salpingeus* of Douglas. *Pterigo-staphylinus* of Cowper, and *Petrosalpingo-staphilin* of Dumas. It arises from the spinous process of the sphenoid bone, behind the foramen ovale, which transmits the third branch of the fifth pair of nerves, and from the Eustachian tube, not far from its osseous part; it then runs down along the pterygoideus internus, passes over the hook of the internal plate of the pterygoid process by a round tendon, which soon spreads into a broad membrane. It is inserted into the velum pendulum palati, and the semilunar edge of the os palati, and extends as far as the suture which joins the two bones. Generally some of its posterior fibres join with the constrictor pharyngis superior, and palato-pharyngæus. Its use is to stretch the velum, to draw it downwards, and to the side towards the hook. It hath little effect upon the tube, being chiefly connected to its osseous part.

CIRCUMGYRA'TIO. (From *circumgyro*, to turn round.) Circumgyration, or the turning a limb round in its socket.

Circumli'tio. (From *circumlino*, to anoint all over.) A medicine used as a general unction or liniment to the part.

CIRCUMOSSA'LIS. (From *circum*, about, and *os*, a bone.) Surrounding a bone as the periosteum does; or surrounded by a bone.

CIRCUMSCISUS. Circumscised. Applied to a membranous capsule, separating into two parts by a complete circular fissure.

CI'RCUS. (Κιρκος; from *carka*, a Caldean word, to surround.) 1. A circle or ring.

2. A circular bandage.

Cirne'sis. (From κιρναω, to mix.) An union of separate things.

CIRRUS. (From κερας, a horn, because it has the appearance of a horn.) *Cirrhus.* A clasper or tendril. One of the *fulcra* or props of plants. A long, cylindrical, slender, spiral body, issuing from various parts of plants.

From their *origin*, Cirri are distinguished into,

1. *Foliar*, when they are a continuation of the midrib of a simple leaf; as in *Fumaria claviculata, Mimosa scandens*, and *Gloriosa superba.*

2. *Petiolar*, when terminating the common petiole of a compound leaf; as in *Pisum sativum.* This is sometimes distinguished by the number of leaflets which grow under it: hence *cirri diphylli, tetraphylli*, and *polyphylli.*

3. *Peduncular*, when they proceed from the peduncle; as in *Vitis vinifera.*

4. *Axillary*, which arise from the stem or branches in the axillæ of the leaves; as in *Passiflora incarnata.*

5. *Subaxillary*, when they originate below the leaf.

6. *Lateral*, when at the side of it; as in *Bryonia.*

From the division of its apex, a Cirrus is,

1. *Simple*, consisting of one undivided piece; as in *Momordica balsaminea, Passiflora quadrangularis*, and *Bryonia dioica.*

2. *Compound*, consisting of a stalk variously branched or divided.

3. *Bifid*, when it has two divisions; as in *Vitis vinifera, Lathyrus palustris, Ervum tetraspermum*, &c.

4. *Trifid*, when there are three; as in *Bignonia unguis*, and *Lathyrus hirsutus.*

5. *Multifid*, or *branched* when the divisions are more numerous; as in *Lathyrus latifolius*, and *Cobea scandens.*

From its *convolution* into,

1. *Convolute*, when all the gyrations are regular in the same direction; as in *Hedera quinquefolia.*

2. *Revolute*, winding itself irregularly, sometimes on one side, sometimes on the other; as in *Passiflora incarnata.*

CIRROSUS. Having a cirrus or tendril. Applied to a leaf tipped with a tendril; as in *Gloriosa* and *Hagellaria*, two Indian plants.

Ci′rsium arvense. (From κιρσος, a vein or swelling of a vein, which this herb was supposed to heal.) The common way thistle, or *Serratula arvensis* of Linnæus.

Cirsoce′le. See *Circocele.*

CIRSOI′DES. (From κιρσος, a varix, and ειδος, likeness.) Resembling a varix: an epithet applied by Rufus Ephesius to the upper part of the brain.

CI′RSOS. (Κιρσος; from κιρσοω, to dilate.) A preternatural distention of any part of a vein. See *Varix.*

Ci′ssa. (From κισσα, a gluttonous bird.) A depraved appetite, proceeding from previous gluttony and voracity.

CISSA′MPELOS. (From κισσος, ivy, and αμπελος, the vine.) The name of a genus of plants in the Linnæan system. Class, *Diœcia*; Order, *Monadelphia.* The wild wine with leaves like ivy.

Cissampelos pareira. The systematic name of the *Pareira brava; Pareyra; Ambutua; Butua; Overo butua.* The root of this plant, *Cissampelos—foliis peltatis cordatis emarginatis*, of Linnæus; a native of South America and the West Indies, has no remarkable smell, but to the taste it manifests a notable sweetness of the liquorice kind, together with a considerable bitterness, and a slight roughness covered by the sweet matter. The facts adduced on the utility of the *radix pareiræ bravæ* in nephritic and calculous complaints, are principally by foreigners, and no remarkable instances of its efficacy are recorded by English practitioners.

Cissa′rus. See *Cistus Creticus.*

Cissi′num. (From κισσος, ivy.) The name of a plaster mentioned by Ægineta.

CI′STA. (From κειμαι, to lie.) A cyst.

CISTE′RNA. (From *cista*, a cyst.) The fourth ventricle of the brain is so called from its cavity; also the lacteal vessels in the breasts of women.

Ci′sthorus. See *Cistus Creticus.*

CISTIC. See *Cystic.*

Cistic oxyde. See *Calculus.*

CI′STUS. (Κιστος, the derivation of which is uncertain; perhaps from *kis*, Heb.) The name of a genus of plants in the Linnæan system. Class, *Polyandria*; Order, *Monogynia.* The Cistus.

Cistus creticus. The systematic name of the plant from which the ladanum of the shops is obtained, called also *Cistus ladanifera; Cisthorus; Cissarus; Dorycinium. Cistus—arborescens extipulatus, foliis spatulato-ovatis petiolatis enerviis scabris, calycinis lanceolatis* of Linnæus. The resinous juice called ladanum exudes upon the leaves of this plant in Candia, where the inhabitants collect it by lightly rubbing the leaves with leather, and afterwards scraping it off, and forming it into irregular masses for exportation. Three sorts of ladanum have been described by authors, but only two are to be met with in the shops. The best, which is very rare, is in dark-coloured masses, of the consistence of a soft plaster, and growing still softer on being handled; the other is in long rolls, coiled up, much harder than the preceding, and not so dark. The first has commonly a small, and the last a large admixture of fine sand, without which they cannot be collected pure, independently of designed abuses: the dust blown on the plant by winds, from the loose sands among which it grows, being retained by the tenacious juice. The soft kind has an agreeable smell, and a lightly pungent bitterish taste: the hard is much weaker. Ladanum was formerly much employed internally as a pectoral and adstringent in catarrhal affections, dysenteries, and several other diseases; at present, however, it is wholly confined to external use, and is an ingredient in the stomachic plaster, *emplastrum ladani.*

Cistus humilis. A name most probably of the *Lichen caninus* of Linnæus.

Cistus ladanifera. See *Cistus creticus.*

Cistus ledon. See *Ledum palustre.*

CITE′SIUS (Citois,) Francis, of Poitiers, in France, who, after graduating at Montpelier in 1596, and practising a few years in his native city, went to Paris, and acquired great celebrity, being made physician to Cardinal Richelieu. He published a treatise on the Colica Pictonum, which was much esteemed, noticing its termination in paralysis of the extremities. He also gave an account of a girl who had fasted for three years; in which case he appears to have been imposed upon. In another publication he advocates repeated bleeding, as well as purging, in small-pox, and other fevers of an inflammatory type. He died in 1652, at the advanced age of 80.

Ci′tharus. (From κιθαρα, a harp.) The breast is sometimes so named from its shape.

CITRA′GO. (From *citrus*, a citron; so called from its citron-like smell.) *Citraria.* Baum. See *Melissa.*

CI′TRAS. (*Citras atis.* fœm.: from *citrus*, the lemon.) A citrate. A salt formed by the union of the citric acid, or acid of lemons, with the salifiable bases; as *citrate of ammonia, citrate of potassa.*

CITRATE. See *Citras.*

Ci′trea. See *Citrus medica.*

CI′TREUM. (From *citrus.*) The citron-tree. See *Citrus medica.*

CI′TRIC ACID. *Acidum citricum.* "The juice of lemons or limes, has all the characters of an acid of considerable strength; but on account of the mucilaginous matter with which it is mixed, it is very soon altered by spontaneous decomposition. Various methods have been contrived to prevent this effect from taking place, in order that this wholsesome and agreeable acid might be preserved for use in long voyages, or other domestic occasions. The juice may be kept in bottles under a thin stratum of oil, which indeed prevents, or greatly retards, its total decomposition; though the original fresh taste soon gives place to one which is much less grateful. In the East Indies it is evaporated to the consistence of a thick extract. If this operation be carefully performed by a very gentle heat, it is found to be very effectual. When the juice is thus heated, the mucilage thickens, and separates in the form of flocks, part of which subside, and part rise to the surface: these must be taken out. The vapours which arise are not acid. If the evaporation be not carried so far as to deprive the liquid of its fluidity, it may be long preserved in well closed bottles; in which, after some weeks' standing, a farther portion of mucilage is separated, without any perceptible change in the acid.

Of all the methods of preserving lemon-juice, that of concentrating it by frost appears to be the best, though in the warmer climates it cannot conveniently be practised. Lemon-juice, exposed to the air in a temperature between 50° and 60°, deposits in a few hours a white semi-transparent mucilaginous matter, which leaves the fluid, after decantation and filtration, much less alterable than before. This mucilage is not of a gummy nature, but resembles the gluten of wheat in its properties: it is not soluble in water when dried. More mucilage is separated from lemon-juice by standing in closed vessels. If this depurated lemon-juice be exposed to a degree of cold of about seven or eight degrees below the freezing point, the aqueous part will freeze, and the ice may be taken away as it forms; and if the process be continued until the ice begins to exhibit signs of acidity, the remaining acid will be found to be reduced to about one-eighth of its original quantity, at the same time that its acidity will be eight times as intense, as is proved by its requiring eight times the quantity of alkali to saturate an equal portion of it. This concentrated acid may be kept for use, or, if preferred, it may be made into a dry lemonade, by adding six times its weight of fine loaf sugar in powder.

The above processes may be used when the acid of lemons is wanted for domestic purposes, because they leave it in possession of the oils, or other principles, on which its flavour peculiarly depends; but in chemical researches, where the acid itself is required to be had in the utmost purity, a more elaborate process must be used. Boiling lemon-juice is to be saturated with powdered chalk, the weight of which is to be noted, and the powder must be stirred up from the bottom, or the vessel shaken from time to time. The neutral saline compound is scarcely more soluble in water than selenite; it therefore falls to the bottom, while the mucilage remains suspended in the watery fluid, which must be decanted off; the remaining precipitate must then be washed with warm water until it comes off clear. To the powder thus edulcorated, a quantity of sulphuric acid, equal the chalk in weight, and diluted with ten parts of water, must be added, and the mixture boiled a few minutes. The sulphuric acid combines with the earth, and forms sulphate of lime, which remains behind when the cold liquor is filtered, while the disengaged acid of lemons remains dissolved in the fluid. This last must be evaporated to the consistence of a thin syrup, which yields the pure citric acid in little needle-like crystals. It is necessary that the sulphuric acid should be rather in excess, because the presence of a small quantity of lime will prevent the crystallisation. This excess is allowed for above.

Its taste is extremely sharp, so as to appear caustic. It is among the vegetable acids the one which most powerfully resists decomposition by fire.

In a dry and warm air it seems to effloresce; but it absorbs moisture when the air is damp, and at length loses its crystalline form. A hundred parts of this acid are soluble in seventy-five of water at 60°. Though it is less alterable than most other solutions of vegetable acids, it will undergo decomposition when long kept.

It is not altered by any combustible substance; charcoal alone appears to be capable of whitening it. The most powerful acids decompose it less easily than they do other vegetable acids; the sulphuric evidently converts it into acetic acid. The nitric acid likewise, if employed in large quantity, and heated on it a long time, converts the greater part of it into acetic acid, and a small portion into oxalic.

The *citrate of lime* has been mentioned already, in treating of the mode of purifying the acid.

The *citrate of potassa* is very soluble and deliquescent.

The *citrate of soda* has a dull saline taste; dissolves in less than twice its weight of water; crystallises in six-sided prisms with flat summits; effloresces slightly, but does not fall to powder; boils up, swells, and is reduced to a coal on the fire. Lime water decomposes it, but does not render the solution turbid, notwithstanding the little solubility of citrate of lime.

Citrate of ammonia is very soluble; does not crystallise unless its solution be greatly concentrated; and forms elongated prisms.

Citrate of magnesia does not crystallise. When its solution had been boiled down, and it had stood some days, on being slightly shaken it fixed in one white opaque mass, which remained soft, separating from the sides of the vessel, contracting its dimensions, and rising in the middle like a kind of mushroom.

All the citrates are decomposed by the powerful acids, which do not form a precipitate with them, as with the oxalates and tartrates. The oxalic and tartaric acids decompose them, and form crystallised or insoluble precipitates in their solutions. All afford traces of acetic acid, or a product of the same nature, on being exposed to distillation: this character exists particularly in the metallic citrates. Placed on burning coals they melt, swell up, emit an empyreumatic smell of acetic acid, and leave a light coal. All of them, if dissolved in water, and left to stand for a time, undergo decomposition, deposit a flocculent mucus which grows black, and leaves their bases combined with carbonic acid, one of the products of the decomposition. Before they are completely decomposed, they appear to pass to the state of acetates.

The affinities of the citric acid are arranged by Vauquelin in the following order: barytes, lime, potassa, soda, strontian, magnesia, ammonia, alumina. Those for zircone, glucine, and the metallic oxides, are not ascertained.

The citric acid is found in many fruits united with the malic acid.

Citric acid being more costly than tartaric, may be occasionally *adulterated* with it. This fraud is discovered, by adding slowly to the acid dissolved in water a solution of subcarbonate of potassa, which will give a white pulverulent precipitate of tartar, if the citric be contaminated with the tartaric acid. When one part of citric acid is dissolved in 19 of water, the solution may be used as a substitute for lemon-juice. If before solution the crystals be triturated with a little sugar and a few drops of the oil of lemons, the resemblance to the native juice will be complete. It is an antidote against sea scurvy; but the admixture of mucilage and other vegetable matter in the recent fruit of the lemon, has been supposed to render it preferable to the pure acid of the chemist."—*Ure's Chem. Dict.*

CITRINA'TIO. Complete digestion.

CITRI'NULA. (A diminutive of *citrus.*) A small citron or lemon.

CITRON. See *Citrus medica.*

Citrul, Sicilian. See *Cucurbita citrullus.*

CITRU'LLUS. See *Cucurbita citrullus.*

CI'TRUS. 1. The name of a genus of plants in the Linnæan system. Class, *Polyadelphia;* Order, *Icosandria.*

2. The name of the lemon. See *Citrus medica.*

CITRUS AURANTIUM. The systematic name of the orange tree and fruit. *Aurantium; Aurantium Hispalense; Aurantium Chinense; Malus aurantia major; Malus aurantia; Aurantium vulgare; Malus aurantia vulgaris; Mala aurea; Chrysomelia; Nerantia; Martianum pomum; Poma aurantia.* The China and Seville orange are both only varieties of the same species: *Citrus:—petiolis alatis, foliis acuminatis,* of Linnæus. The latter is specified in our pharmacopœias; and the *flowers, leaves, yellow rind* and *juice,* are made use of for different medical purposes.

The flowers, *flores naphæ,* are highly odoriferous, and are used as a perfume; they are bitter to the taste; they give their taste and smell both to water and to spirit, but most perfectly to rectified spirit of wine. The water which is distilled from these flowers, is called *aqua florum naphæ.* In distillation, they yield a small quantity of essential oil, which is called *oleum* vel *essentia neroli:* they are brought from Italy and France. Orange flowers were, at one time, said to be an useful remedy in convulsive diseases; but experience has not confirmed the virtues attributed to them.

The *leaves* have a bitterish taste, and yield, by distillation, an essential oil; indeed, by rubbing them between the fingers and the thumb, they manifest considerable fragrance. They have been applied for the same purposes as the flowers, but without success.

The *yellow rind* of the fruit, freed from the white fungous part, has a grateful aromatic flavour, and a warm, bitterish taste. Infused in boiling water, it gives out nearly all its smell and taste; cold water extracts the bitter, but very little of the flavour. In distillation, a light, fragrant, essential oil rises, without the bitter. Its qualities are those of an aromatic and bitter. It has been employed to restore the tone of the stomach, and is a very common addition to combinations of bitters, used in dyspepsia. It has likewise been given in intermittents, in doses of a drachm, twice or thrice a day. It is also much celebrated as a powerful remedy, in menorrhagia, and immoderate uterine evacuations.

The *juice* of Seville oranges is a grateful acid, which, by allaying heat, quenching thirst, promoting various excretions, and diminishing the action of the sanguiferous system, proves extremely useful in both ardent and putrid fevers; though the China orange juice, as impregnated with a larger proportion of sugar, becomes more agreeable, and may be taken in larger quantities. The Seville orange juice is particularly serviceable as an antiscorbutic, and alone will prevent or cure scurvy in the most apparently desperate circumstances. In dyspepsia, from putrid bile in the stomach, both lemon and orange juice are highly useful.

CITRUS MEDICA. The systematic name of the lemon-tree. *Limon; Limonia mala; Malus medica; Malus limonia acida; Citrea malus; Citrus.* The tree which affords the lemon, is the *Citrus:—petiolis linearibus,* of Linnæus: a native of the upper part of Asia, but cultivated in Spain, Portugal, and France. The juice, which is much more acid than that of the orange, possesses similar virtues. It is always preferred where a strong vegetable acid is required. Saturated with the fixed vegetable alkali, it forms the citrate of potassa, which is in frequent extemporaneous use in febrile diseases, and by promoting the secretions, especially that of the skin, proves of considerable service in abating the violence of fever. This medicine is also often employed to restrain vomiting. As an antiscorbutic, lemon juice has been often taken on board ships destined for long voyages; but even when well depurated of its mucilaginous parts, it is found to spoil by long keeping. To preserve it in purity for a considerable length of time, it is necessary that it should be brought to a highly concentrated state, and for this purpose it has been recommended to expose the juice to a degree of cold sufficient to congeal the aqueous and mucilaginous parts. After a crust of ice is formed, the juice is poured into another vessel; and, by repeating this process several times, the remaining juice, it has been said, has been concentrated to eight times its original strength, and kept without suffering any material change for several years. Whytt found the juice of lemon to allay hysterical palpitations of the heart, after various other medicines had been experienced ineffectual; and this juice, or that of oranges, taken to the quantity of four or six ounces in a day, has sometimes been found a remedy in the jaundice. The exterior rind of the lemon is a very grateful aromatic bitter, not so hot as orange peel, and yielding in distillation [illegible] less quantity of oil, which is extremely light, almost colourless, and generally brought from the southern parts of Europe, under the name of Essence of Lemons. The lemon-peel, though less warm, is similar in its qualities to that of the orange, and is employed with the same intentions. The pharmacopœias direct a syrup of the juice *syrupus limonis,* and the peel enters into some vinous and aqueous bitter infusions; it is also ordered to be candied; and the essential oil is an ingredient in some formulæ.

The citron-tree is also considered as belonging to the same species, the *Citrus medica* of Linnæus. Its fruit is called *Cedromela,* which is larger and less succulent than the lemon; but in all other respects the citron and lemon trees agree. The citron juice, when sweetened with sugar, is called by the Italians *Agro di cedro.* The *Citrus mella rosa* of Lamarck, is another variety of the *Citrus medica* of Linnæus. It was produced, at first, casually, by an Italian's grafting a citron on a stock of a bergamot pear-tree; whence the fruit produced by this union participated both of the citron-tree and the pear-tree. The essence prepared from this fruit is called essence of bergamote and essentia de cedra.

CI'TTA. A voracious appetite.

CITTO'SIS. See *Chlorosis.*

CIVET-CAT. See *Zibethum.*

CIVE'TTA. (From *sebet,* Arabian.) *Zibethum.* Civet; an unctuous odoriferous drug used by perfumers, collected betwixt the anus and the organs of generation of a fierce carnivorous quadruped met with in China and the East and West Indies, called a civet-cat, the *Viverra Zibethum* of Linnæus, but bearing a greater resemblance to a fox or marten than a cat.

Several of these animals have been brought into Holland, and afford a considerable branch of commerce, particularly at Amsterdam. The civet is squeezed out in summer every other day, in winter twice a-week: the quantity procured at once is from two scruples to a drachm or more. The juice thus collected is much purer and finer than that which the animal sheds against shrubs or stones in its native climates.

Good civet is of a clear yellowish or brownish colour, not fluid, nor hard, but about the consistence of butter or honey, and uniform throughout; of a very strong smell; quite offensive when undiluted; but agreeable when only a small portion of civet is mixed with a large one of other substances.

Civet unites with oils, but not with alkohol. Its nature is therefore not resinous.

CLAP. See *Gonorrhœa.*

CLA'RET. (*Claretum;* from *clareo*, to be clear.) A French wine, that may be given with great advantage, as a tonic and antiseptic, where red port wine disagrees with the patient; and in typhoid fevers of children and delicate females, it is far preferable, as a common drink.

CLARE'TUM. 1. The wine called *claret.* See *Claret.*

2. A wine impregnated with spices and sugar, called by some *Vinum Hippocraticum.*

3. A *Claretum purgatorium*, composed of a vinous infusion of glass of antimony with cinnamon water and sugar, is mentioned by Schroeder.

CLARIFICA'TIO. The depuration of any thing, or process of freeing a fluid from heterogeneous matter, or feculencies.

CLASS. (*Classis;* from καλεω, *congrego*, a class being nothing more than a multitude assembled apart.) The name of a primary division of bodies in natural history.

CLARY. See *Salvia.*

CLA'SIS. (From κλάω, to break.) *Clasma.* A fracture.

CLAU'STRUM. (From *claudo*, to shut.) *Cleithrum gutturis.* Any aperture which has a power of contracting itself, or closing its orifice by any means; as the passage of the throat.

Claustrum virginitatis. The hymen.

CLAUSU'RA. (From *claudo*, to shut.) An imperforation of any canal or cavity in the body. Thus *clausura uteri* is a preternatural imperforation of the uterus; *clausura tubarum Fallopiarum*, a morbid imperforation of the Fallopian tubes, mentioned by Ruysch as one cause of infecundity.

Clava rugosa. See *Acorus calamus.*

CLAVARIA. (From *clava*, a club.) The name of a genus of plants, Class, *Cryptogamia;* Order, *Fungi.* Club-shaped fungus.

Clavaria coralloides. The systematic name of the *Fungus coralloides* of old writers; called also *crotelus.* It was once used as a strengthener and astringent.

CLAVA'TIO. (From *clava*, a club.) A sort of articulation without motion, where the parts are, as it were, driven in with a hammer, like the teeth in the sockets. See *Gomphosis.*

CLAVATUS. Clubbed. Applied to parts of plants, as the stigma of the Genipi.

Clavellatus. (From *clavus*, a wedge. The name cineres clavellati originated from the little wedges or billets, into which the wood was cut to burn for potassa.) See *Potassa impura.*

CLA'VICLE. (*Clavicula*, diminutive of *clavis;* so called from its resemblance to an ancient key.) Collar-bone. The clavicle is placed at the root of the neck, and at the upper part of the breast. It extends across, from the tip of the shoulder to the upper part of the sternum; it is a round bone, a little flattened towards the end, which joins the scapula; it is curved like an Italic *S*, having one curve turned out towards the breast: it is useful as an arch, supporting the shoulders, preventing them from falling forwards upon the breast, and making the hands strong antagonists to each other; which, without this steadying, they could not have been.

1. The thoracic end, that next the sternum, or what may be called the inner head of the clavicle, is round and flat, or button-like; and it is received into a suitable hollow on the upper piece of the sternum. It is not only like other joints surrounded by a capsule or purse; it is further provided with a small moveable cartilage, which, like a friction wheel in machinery, saves the parts and facilitates the motions, and moves continually as the clavicle moves.

2. But the outward end of the clavicle is flattened, as it approaches the scapula, and the edge of that flatness is turned to the edge of the flattened acromion, so that they touch but in one single point. This outer end of the clavicle, and the corresponding point of the acromion, are flattened and covered with a crust of cartilage; but the motion here is very slight and quite insensible: they are tied firmly by strong ligaments; and we may consider this as almost a fixed point, for there is little motion of the scapula upon the clavicle: but there is much motion of the clavicle upon the breast, for the clavicle serves as a shaft, or axis, firmly tied to the scapula, upon which the scapula moves and turns, being connected with the trunk only by this single point, viz. the articulation of the clavicle with the breast-bone.

CLAVI'CULA. See *Clavicle.*

CLAVI'CULUS. See *Clavicle.*

CLA'VIS. (From *claudo*, to shut.) The clavicle.

CLA'VUS. (A nail.) 1. A corn called *clavus*, from its resemblance to the head of a nail; *Ecphyma clavus* of Good. A roundish, horny, cutaneous extuberance, with a central nucleus, sensible at its base; found chiefly on the toes from the pressure of tight shoes.

2. A painful and often an intermitting affection of the head, and mostly a severe pulsating pain in the forehead, which may be covered by one's thumb, giving a sensation like as if a nail were driven into the part. When connected with hysterics, it is called *Clavus hystericus.*

3. An artificial palate.

4. Diseased uterus.

Clavus hystericus. See *Clavus.*

Clavus oculorum. A staphyloma, or tumour on the eyelids.

CLAY. *Argilla.* Argillaceous earth, of which there are many kinds, and being opaque and non-crystallised bodies, of dull fracture, afford no good principle for determining their species; yet as they are extensively distributed in nature, and are used in many arts, they deserve particular attention. The argillaceous minerals are all sufficiently soft to be scratched by iron; they have a dull or even earthy fracture; they exhale, when breathed on, a peculiar smell called argillaceous. The clays form with water a plastic paste, possessing considerable tenacity, which hardens with heat, so as to strike fire with steel. Marles and chalks also soften in water, but their paste is not tenacious, nor does it acquire a siliceous hardness in the fire. The affinity of the clays for moisture is manifested by their sticking to the tongue, and by the intense heat necessary to make them perfectly dry. The odour ascribed to clays breathed upon, is due to the oxide of iron mixed with them. Absolutely pure clays emit no smell.

1. *Porcelain earth*, the kaolin of the Chinese.—This mineral is friable, meagre to the touch, and, when pure, forms with difficulty a paste with water.

2. *Potters' clay*, or *plastic clay.*—The clays of this variety are compact, smooth, and almost unctuous to the touch, and may be polished by the finger when they are dry. They have a great affinity to water, form a tenacious paste, and adhere strongly to the tongue.

3. *Loam.*—This is an impure potters' clay mixed with mica and iron ochre.

4. *Variegated clay.*—Is striped or spotted with white, red, or yellow colours.

5. *Slate clay.*—Colour, grey, or greyish-yellow.

6. *Claystone.*—Colour, grey, of various shades, sometimes red, and spotted or striped.

7. *Adhesive slate.*—Colour, light greenish-grey.

8. *Polishing slate* of Werner.—Colour, cream-yellow, in alternate stripes.

9. *Common clay* may be considered to be the same as *loam.*

CLAY, PURE. See *Alumina.*

CLAY-SLATE. Argillaceous slate. Argillite of Kirwan. A mineral which is extensively distributed, forming a part of both primitive and transition mountains of slate, is found in many countries.

CLEAVAGE. This term is applied to the mechanical division of crystals, by showing the direction in which their *laminæ* can separate, enables us to determine the mutual inclination of these *laminæ:* Werner called it *durchgang*, but he attended only to the number of directions in which this mechanical division of the plates, or cleavage, could be effected. In the interior of many minerals, the direction of the cleavage may be frequently seen, without using any mechanical violence.

CLEAVERS. See *Galium aparine.*

CLEGHORN, GEORGE, was born near Edinburg in 1716; and after studying in that city, went at the age of twenty to Minorca, as a regimental surgeon. During the thirteen years that he spent there, he sedulously studied the natural productions of the island. In 1750, coming to London, he published his "Treatise on the Diseases of Minorca," which displays great observation and ability. He then went to Dublin, and gave lectures on anatomy with such success, that he was soon after appointed public professor; and in 1774, an honorary member of the College of Physicians there. He died in 1789.

CLEI′DION. *Clidion.* The epithet of a pastil, described by Galen and Paulus Ægineta; and it is the name also of an epithem described by Aëtius.

CLEIDO′MA. (From κλειδοω, to close.) A pastil, or troch. Also the clavicle.

CLEIDOMASTOIDE′US. (From κλεις, the clavicle, and μαστοειδης, the mastoid process.) See *Sterno-cleido-mastoideus.*

CLEISA′GRA. (From κλεις, the clavicle, and αγρα, a prey.) The gout in the articulation of the clavicles.

CLEI′THRON. (From κλειδω, to shut.) See *Claustrum.*

CLE′MATIS. (From κλημα, a tendril; so named from its climbing up trees, or any thing it can fasten upon with its tendrils.) The name of a genus of plants in the Linnæan system. Class, *Polyandria;* Order, *Polygynia.*

CLEMATIS RECTA. The systematic name of the upright virgin's-bower. *Flammula Jovis. Clematis—foliis pinnatis, foliolis ovato lanceolatis integerrimis, caule erecto, floribus pentapetalis tetrapetalisque* of Linnæus. More praises have been bestowed upon the virtue which the leaves of this plant are said to possess, when exhibited internally, as antivenereal, by foreign physicians than its trials in this country can justify. The powdered leaves are sometimes applied externally to ulcers, as an escharotic.

CLEMATIS VITALBA. The systematic name of the traveller's-joy. *Vitalba; Atragene; Viorna; Clematis arthragene* of Theophrastus. This plant is common in our hedges, and is the *Clematis—foliis pinnatis, foliolis cordatis scandentibus* of Linnæus. Its leaves, when fresh, produce a warmth on the tongue, and if the chewing is continued, blisters arise. The same effect follows their being rubbed on the skin. The plant has been administered internally to cure lues venerea, scrofula, and rheumatism. In France, the young sprouts are eaten, when boiled, as hoptops are in this country.

CLEMATI′TIS. The same as clematis.

CLEO′NIS COLLYRIUM. The name of a collyrium described by Celsus.

CLEONIS GLUTEN. An astringent formula of myrrh, frankincense, and white of egg mixed together.

CLE′PSYDRA. (From κλεπτω, to conceal, and υδωρ, water.) Properly, an instrument to measure time by the dropping of water through a hole, from one vessel to another; but it is used to express a chemical vessel, perforated in the same manner. It is also an instrument mentioned by Paracelsus, contrived to convey suffumigations to the uterus in hysterical cases.

CLEYER, ANDREW, was born at Cassel, in the beginning of the 17th century. After studying medicine, he went as physician to Batavia, where he resided many years. He transmitted several interesting communications to the Imperial Academy, of which he had been chosen a member, particularly "An Account of Hydatids found in a Human Stomach," and "Of the Custom of the Indians of taking Opium;" also descriptions and drawings of the plants indigenous in Java, especially the moxa, ginseng, and tea-plant. He likewise published, in 1680, a curious specimen of Chinese medicine.

CLI′BANUS. (Quasi καλιβανος; from καλυπτω, to conceal.) A portable furnace, or still, in which the materials to be wrought on are shut up.

CLIFTON, FRANCIS, after studying at Oxford, came to London, and was admitted Fellow of the College of physicians, as well as of the Royal Society, about the year 1730. Two years after he published on "The State of Physic, ancient and modern, with a Plan for improving it;" in which a law is proposed, to compel practitioners to send to a public institution descriptions of the several cases which come under their care. He was also author of "A plain and sure Way of practising Physic;" and translated some parts of Hippocrates into English, with notes.

Clima′cter. (From κλιμαζω, to proceed gradually.) The progression of the life of man. It is usually divided into periods of seven years.

Climacteric. See *Septenary.*

CLIMATE. The prevailing constitution of the atmosphere, relative to heat, wind and moisture, peculiar to any region. This depends chiefly on the latitude of the place, its elevation above the level of the sea, and its insular or continental position. Springs which issue from a considerable depth, and caves about 50 feet under the surface, preserve a uniform temperature through all the vicissitudes of the season. This is the mean temperature of that country.

It appears very probable, that the climates of European countries were more severe in ancient times than they are at present. Cæsar says, that the vine could not be cultivated in Gaul, on account of its winter-cold. The rein-deer, now found only in the zone of Lapland, was then an inhabitant of the Pyrenees. The Tiber was frequently frozen over, and the ground about Rome covered with snow for several weeks together, which almost never happens in our times. The Rhine and the Danube, in the reign of Augustus, were generally frozen over, for several months of winter. The barbarians who overran the Roman empire a few centuries afterwards, transported their armies and waggons across the ice of these rivers. The improvement that is continually taking place in the climate of America, proves, that the power of man extends to phenomena, which, from the magnitude and variety of their causes, seemed entirely beyond his controul. At Guiana, in South America, within five degrees of the line, the inhabitants living amid immense forests, a century ago, were obliged to alleviate the severity of the cold by evening fires. Even the duration of the rainy season has been shortened by the clearing of the country, and the warmth is so increased, that a fire now would be deemed an annoyance. It thunders continually in the woods, rarely in the cultivated parts.

Drainage of the ground, and removal of forests, however, cannot be reckoned among the sources of the increased warmth of the Italian winters. Chemical writers have omitted to notice an astronomical cause of the progressive amelioration of the climates of the northern hemisphere. In consequence of the apogee portion of the terrestrial orbit being contained between our vernal and autumnal equinox, our summer half of the year, or the interval which elapses between the sun's crossing the equator in spring, and in autumn, is about *seven* days longer than our winter half year. Hence also, one reason for the relative coldness of the southern hemisphere.

CLI′MAX. (From κλιμαζω, to proceed.) A name of some antidotes, which, in regular proportion, increased or diminished the ingredients of which it was composed, e. g. ℞. *Chamædryos* ℥jjj. *Centaurii* ℥jj. *Hyperici* ℥j.

Climbing birthwort. See *Aristolochia clematitis.*

Climbing stem. See *Caulis.*

CLI′NICAL. (*Clinicus*; from κλινη, a bed.) Any thing concerning a bed: thus clinical lectures, notes, a clinical physician, &c.; which mean lectures given at the bedside, observations taken from patients when in bed, a physician who visits his patients in their bed, &c.

CLINKSTONE. A stone of an imperfectly slaty nature, which rings like metal, when struck with a hammer.

CLI′NOID. (*Clinoideus*; from κλινη, a bed, and ειδος, resemblance.) Resembling a bed. The four processes surrounding the sella turcica of the sphenoid bone are so called, of which two are anterior, and two posterior.

Clinomastoide′us. A corruption of cleidomastoideus. See *Sterno-cleido-mastoideus.*

CLINOMETER. An instrument for measuring the dip of mineral strata.

Cli′ssus. A chemical term denoting mineral compound spirits; but antimony is considered as the basis clyssi. See *Clyssus.*

Clito′ridis musculus. See *Erector clitoridis.*

CLI′TORIS. (From κλειω, to enclose, or hide; because it is hid by the labia pudendorum.) *Columella.* A small glandiform body, like a penis in miniature, and, like it, covered with a prepuce, or fore-skin. It is situated above the nymphæ, and before the opening of the urinary passage of women. Anatomy has discovered, that the clitoris is composed, like the penis, of a cavernous substance, and of a glans, which has no perforation, but is like that of the penis, exquisitely sensible. The clitoris is the principal seat of pleasure: during coition it is distended with blood, and after the venereal orgasm it becomes flaccid and falls. Instances have occurred where the clitoris was so enlarged as to enable the female to have venereal commerce with others; and, in Paris, this fact was made a public exhibition of to the faculty. Women thus formed appear to partake, in their general form, less of the female character, and are termed hermaphrodites. The clitoris in children is larger, in proportion, than in full-grown women: it often projects beyond the external labia at birth.

CLITORI′SMUS. (From κλειτορις; the clitoris.) An enlargement of the clitoris.

CLO′NIC. (From κλονεω, to move to and fro.) See *Convulsion.*

Clono′des. (From κλονεω, to agitate.) A strong unequal pulse.

CLONUS. (From κλονεω, to agitate.) The name of a genus of disease in the Class, *Neuroses*; Order, *Lenetica*, of Good's Nosology. Clonic spasm, comprising six species: *Clonus singultus, sternutatio, palpitatio, nictitatio, subsultus*, and *pandiculatio.*

CLOVE. See *Eugenia caryophyllata.*

Clove bark. See *Myrtus caryophyllata.*

Clove gilliflower. See *Dianthus caryophyllus.*

Clove pink. See *Dianthus caryophyllus.*

Cloven leaf. See *Leaf.*

CLOWES, William, an eminent English surgeon of the 16th century, received his education under George Keble, whose skill he strongly commends. After serving for some time professionally in the navy, he settled in London, and was made surgeon to Christ's and St. Bartholomew's hospitals, and appears to have had considerable practice. In 1586, he was sent to the Low-countries, to the assistance of the army under the Earl of Leicester; and on his return was appointed surgeon to the Queen. His works are in the English language, but evince much learning, as well as skill in his profession. The first which he published was on the lues venerea, in 1585; in which he notices the increasing frequency of that disease, and states that in five years he had cured above a thousand patients labouring under it at St. Bartholomew's hospital. But his most celebrated publication appeared three years after, on the method of treating wounds of various kinds, the result of extensive experience, sanctioned by references to the most approved writers. He appears to have possessed an enlarged understanding, and was very severe on all quacks and impostors; and he may justly be reckoned among the restorers and improvers of surgery in modern times.

CLUNE'SIA. (From *clunes*, the buttocks.) An inflammation of the buttocks.

CLU'PEA. The name of a genus of fishes, in the Linnæan system.

Clupea alosa. The Linnæan name for the shad or chad, the flesh of which is by some commended as a restorative.

Clupea encrasicolus. The anchovy, a little fish found in great abundance, about the island of Gorgona, near Leghorn. It is prepared for sale, by salting and pickling. It is supposed the ancient Greeks and Romans prepared a kind of garum for the table from this fish. Its principal use is, as a sauce for seasoning.

CLU'SIA. (So called in memory of Charles Clusius, an eminent botanist.) The name of a genus of plants in the Linnæan system. Class, *Polygamia;* Order, *Monœcia.* Balsam-tree.

CLUSTER. See *Racemus.*

CLU'TIA. (Named after Cluyt, and sometimes spelt *cluytia.*) The name of a genus of plants in the Linnæan system. Class, *Diœcia;* Order, *Gynandria.*

Clutia elutheria. The systematic name of the tree which is by some supposed to afford the cascarilla bark.

Cluy'tia. See *Clutia.*

CLY'DON. Κλυδων. A fluctuation and flatulency in the stomach.

CLYPEA'LIS. (From *clypeus*, a shield.) Formed like a shield.

CLY'SMUS. (From κλυζω, to wash.) *Clysma.* A glyster.

Cly'ssus. *Clissus.* A term anciently used by the chemists for medicines made by the reunion of different principles, as oil, salt, and spirit, by long digestion; but it is not now practised, and the term is almost lost.

Clyssus antimonii. *Clyssus mineralis.* A weak acid of sulphur.

Cly'ster. (*Clysterium.* From κλυζω, to cleanse.) A glyster. See *Enema.*

Cne'mia. (From κνημη, the tibia.) Any part connected with the tibia.

Cnemodactylæ'us. (From κνημη, the tibia, and δακτυλος, a finger, or toe.) A muscle, the origin of which is in the tibia, and insertion in the toes. See *Extensor longus digitorum pedis.*

CNE'SIS. (From κναω, to scratch.) *Cnismos.* A painful itching.

Cnicilæ'on. (From κνικος, cnicus, and ελαιον, oil.) Oil made of the seeds of cnicus. Its virtues are the same with those of the ricinus, but in an inferior degree.

CNI'CUS. (From κναω, to scratch.) The plant used by Hippocrates by this name, is supposed to be the carthamus; but modern botanists exclude it from the species of this plant.

Cnicus cernuus. The systematic name of the nodding cnicus, the tender stalks of which are, when boiled and peeled, eaten by the Siberians as a food.

Cnicus lanatus. *Chamælim verum.* The distaff thistle. Formerly used as a depuration, but now forgotten.

Cnicus oleraceus. Round-leaved meadow thistle. The leaves of this plant, are boiled in the northern parts of Europe, and eaten as we do cabbage.

Cnicus sylvestris. See *Centaurea benedicta.*

Cnidia grana. See *Daphne mezereum.*

Cnidii cocci. See *Daphne mezereum.*

Cnidii grana. See *Daphne mezereum.*

Cnido'sis. (From κνιδη, the nettle.)

1. An itching sensation, such as is perceived from the nettle.

2. A dry ophthalmy.

Cnipo'tes. An itching.

Cni'smos. See *Cnesis.*

Cny'ma. (From κναω, to scrape, or grate.) In Hippocrates it signifies a rasure, puncture, or vellication: also the same as cnesis.

Coadunatæ. (From *coadunare*, to join or gather together.) The name of an order of plants, in Linnæus's Fragments, of a Natural Method.

COA'GULABLE. Possessing the property of coagulation. See *Albumen.*

Coagulable lymph. See *Albumen.*

COAGULA'NT. (*Coagulans;* from *coagulo*, to incrassate, or curdle.) Having the power of coagulating the blood or juices flowing from it.

COAGULA'TION. (*Coagulatio;* from *con*, and *ago*, to drive together.) The separation of the coagulable particles, contained in any fluid, from the more thin and not coagulable particles: thus, when milk curdles, the coagulable particles form the curd; and when acids are thrown into any fluid containing coagulable particles, they form what is called a *coagulum.*

COA'GULUM. A term applied frequently to blood and other fluids, when they assume a jelly-like consistency.

Coagulum aluminis. This is made by beating the white of eggs with a little alum, until it forms a coagulum. It is recommended as an efficacious application to relaxations of the conjunctive membrane of the eye.

COAK. Charred coal.

COAL. A combustible mineral, of which there are many species.

Coalte'rnæ febres. (From *con*, and *alternus*, alternate.) Fevers mentioned by Bellini, which he describes as two fevers affecting the same patient, and the paroxysm of one approaching as that of the other subsides.

COARCTA'TIO. (From *coarcto*, to straighten.) The contraction, or diminution of any thing. Formerly applied to the pulse: it meant a lessening in number.

COARCTATUS. Crowded. A panicle is so called, which is dense or crowded; as in *Phleum paniculatum*, the inflorescence of which, looks, at first sight, like a cylindrical spike; but when bent to either side, separates into branched lobes, constituting a real panicle.

Coarticula'tio. (From *con*, and *articulatio*, an articulation.) That sort of articulation which has manifest motion.

COBALT. A brittle, somewhat soft, but difficultly fusible metal, of a reddish-grey colour, of little lustre, and a sp. gr. of 8.6. Its melting point is said to be 130° Wedgewood. It is generally associated in its ores with nickel, arsenic, iron, and copper; and the cobalt of commerce usually contains a proportion of these metals. To separate them, calcine with four parts of nitre, and wash away, with hot water, the soluble arseniate of potassa. Dissolve the residuum in dilute nitric acid, and immerse a plate of iron in the solution, to precipitate the copper. Filter the liquid and evaporate to dryness. Digest the mass with water of ammonia, which will dissolve only the oxides of nickel and cobalt. Having expelled the excess of alkali by a gentle heat from the clear ammoniacal solution, add cautiously water of potassa, which will precipitate the oxide of nickel.

Filter immediately, and boil the liquid, which will throw down the pure oxide of cobalt. It is reduced to the metallic state by ignition in contact with lamp-black and oil. Laugier treats the above ammoniacal solution with oxalic acid. He then redissolves the precipitated oxalates of nickel and cobalt in concentrated water of ammonia, and exposes the solution to the air. As the ammonia exhales, oxalate of nickel, mixed with ammonia, is deposited. The nickel is entirely separated from the liquid by repeated crystallisations. There remains a combination of oxalate of cobalt and ammonia, which is easily reduced by charcoal to the metallic state. The small quantity of cobalt remaining in the precipitated salt of nickel, is separated by digestion in water of ammonia.

Cobalt is susceptible of magnetism, but in a lower degree than steel and nickel.

Oxygen combines with cobalt in two proportions; forming the dark blue protoxide, and the black deutoxide. The first dissolves in acids without effervescence. It is procured by igniting gently in a retort the oxide precipitated by potassa from the nitric solution. Proust says, the first oxide consists of 100 metal + 19.8 oxygen; and Rothoff maks the composition of the deutoxide 100 + 36.77. If we call the first 18.5, and the second 37; then the prime equivalent of cobalt will be 5.4; and the two oxides will consist of

Protox.	Cobalt, 5.4	100	84.38
	Oxygen, 1.0	18.5	15.62
			100.00
Deutox.	Cobalt, 5.4	100	73
	Oxygen, 2.0	37	27
			100

The precipitated oxide of cobalt, washed and gently heated in contact with air, passes into the state of black peroxide.

When cobalt is heated in chlorine, it takes fire, and forms the chloride. The iodide, phosphuret, and sulphuret of this metal, have not been much examined.

The salts of cobalt are interesting from the remarkable changes of colour which they can exhibit.

Their solution is red in the neutral state, but green with a slight excess of acid; the alkalies occasion a blue-coloured precipitate from the salts of pure cobalt, but reddish-brown when arsenic acid is present; sulphuretted hydrogen produces no precipitate, but hydrosulphurets throw down a black powder, soluble in excess of the precipitant: tincture of galls gives a yellowish-white precipitate; oxalic acid throws down the red oxalate. Zinc does not precipitate this metal.

COBALUS. The demon of mines, which obstructed and destroyed the miners.

COBHAM. The name of a town in Surrey, in the neighbourhood of which is a weak saline purging water.

Co'bra de capello. (From *cobra*, the head, or covering, Spanish.) See *Crotalus horridus*.

Cocao, butter of. See *Butter of Cocao*.

Cocao-nut. See *Cocos nucifera*.

Cocca cnidia. See *Daphne mezereum*.

Cocca'rium. (From κοκκον, a berry.) A very small pill.

COCCINE'LLA. (Diminutive of *coccus*, a berry; from its resemblance to a berry.) See *Coccus cacti*.

Cocco-balsamum. The fruit of the *Amyris gileadensis*.

Coccogni'dia. See *Daphne mezereum*.

COCCOLITE. A mineral of a green colour, of various shades, found with granular limestone, garnet and magnetic iron-stone, in Norway, Sweden, and Spain.

CO'CCOS. See *Daphne mezereum*.

CO'CCULUS. (Diminutive of κοκκος, a berry.) 1. A little berry.

2. The name given by De Candolle, in his *Systema Naturæ*, to a new genus of plants.

3. Cocculus indicus. See *Menispermum cocculus*.

4. Cocculus palmatus. The systematic name of the plant, which affords the calumba root of the pharmacopœias. See *Calumba*.

Co'cculus Indi aromaticus. Jamaica pepper. See *Myrtus pimenta*.

CO'CCUM. A species of capsule, but separated from it by Gærtner, who defines it to be a dry seed-vessel, more or less aggregate, not solitary, the sides of which are elastic, projecting the seeds with great force; as in the *Euphorbia*.

Coccum baphicum. A name for chermes.

CO'CCUS. The name, in entomology, of a tribe of insects.

Coccus cacti. The systematic name of the cochineal animal, or insect. *Coccinella; Coccinilla; Ficus Indiæ grana; Scarabæolus hemisphæricus; Cochinelifera cochinilla; Coccus Americanus; Cochinella; Coccus Indicus; tinctorius.* Cochineal. That which is used is the female insect found on, and collected in South America from, the *Opuntia*, or Indian fig-tree. It possesses stimulating qualities, and is ordered by the College in the *tinctura cardamomi composita*, and *tinctura cinchonæ composita*; but, most probably, merely on account of the beautiful red colour which it imparts to them.

COCCYGE'US. (*Coccygeus*; from κοκκυξ: because it is inserted into the coccyx.) A muscle of the os coccygis, situated within the pelvis. *Ischio-cocigien* of Dumas. It arises tendinous and fleshy, from the spinous process of the ischium, and covers the inside of the sacroischiatic ligament; from this narrow beginning it gradually increases to form a thin fleshy belly, interspersed with tendinous fibres. It is inserted into the extremity of the os sacrum, and nearly the whole length of the os coccygis, laterally. Its use is to support and move the os coccygis forwards, and to tie it more firmly to the sacrum.

CO'CCYGIS OS. (From κοκκυξ, the cuckoo, the bill of which bird it is said to represent.) *Cauda. Ossis sacri acumen. Coccyx.* This bone is a small appendage to the point of the sacrum, terminating this inverted column with an acute point, and found in very different conditions in the several stages of life. In the child, it is merely cartilage, and we can find no point of bone: during youth, it is ossifying into distinct bones, which continue moveable upon each other till manhood: then the separate bones gradually unite with each other, so as to form one conical bone, with bulgings and marks of the pieces of which it was originally composed; but still the last bone continues to move upon the joint of the sacrum, till, in advanced years, it is at last firmly united; later in women than in men, with whom it is often fixed at twenty or twenty-five. It is not, like the os sacrum, flat, but of a roundish form, convex without, and concave inwards; forming with the sacrum the lowest part of the pelvis behind. It has no holes like the sacrum; has no communication with the spinal canal, and transmits no nerves; but points forwards to support the lower parts of the rectum; thus it contracts the lower opening of the pelvis, so as to support effectually the rectum, bladder, and womb; and yet continues so moveable in women as to recede in time of labour, allowing the head of the child to pass.

CO′CCYX. (Κοκκυξ, the cuckoo.) See *Coccygis os.* Also the part in which the os coccygis is placed.

CO′CHENILIN. *Carminium.* The name of the colouring principle of cochineal.

Co′chia. (From κοχαω, to turn or make round.) An ancient name of some officinal pills. The pill of cochia of the shops, in the present day, is the compound colocynth pill.

Co′chineal. See *Coccus cacti.*

CO′CHLEA. (From κοχαζω, to turn round.) A cavity of the internal ear, resembling the shell of a snail, in which are the *modiolus*, or *nucleus*, extending from its basis to the *apex* the *scala tympani*, *scala vestibuli*, and *spiral lamina.* See *Ear.*

Cochlea terrestris. See *Limax.*

COCHLEA′RE. (From *cochlea*, a cockle, the shell of which its bowl represents.) A spoon. *Cochleare amplum* or *magnum* is a table-spoon, calculated to hold half a fluid ounce; *cochleare medium* is a dessert or pap spoon, supposed to hold two tea-spoonfuls; and *cochleare minimum*, a tea-spoon, which holds about one fluid drachm.

COCHLEA′RIA. (From *cochleare*, a spoon; so called from its resemblance.) The name of a genus of plants in the Linnæan system. Class, *Tetradynamia*; Order, *Siliculosa.*

Cochlearia armoracia. The systematic name of the horse-radish; *Raphanus rusticanus; Armoracia; Raphanus marinus; Raphanus sylvestris; Cochlearia—foliis radicalibus lanceolatis crenatis caulinis incisis*, of Linnæus. The root of this plant has long been received into the materia medica, and is also well known at our tables. "It affects the organs both of taste and smell with a quick penetrating pungency; nevertheless it contains in certain vessels a sweet juice, which sometimes exudes in little drops upon the surface. Its pungent matter is of a very volatile kind, being totally dissipated in drying, and carried off in evaporation, or distillation by water; as the pungency exhales, the sweet matter of the root becomes more sensible, though this also is, in a great measure, dissipated or destroyed. It impregnates both water and spirit, by infusion, or by distillation, very richly with its active matters. In distillation with water, it yields a small quantity of essential oil, exceedingly penetrating and pungent."

Dr. Cullen has mentioned every thing necessary to be known respecting the medicinal virtues of horse-radish, we shall therefore transcribe all that the ingenious professor has written on this subject. "The root of this plant only is employed; and it affords one of the most acrid substances of this order (*Siliculosa*,) and therefore proves a powerful stimulant, whether externally or internally employed. Externally, it readily inflames the skin, and proves a rubefacient that may be employed with advantage in palsy and rheumatism; and if its application be long continued, it produces blisters. Taken internally, it may be so managed as to relieve hoarseness, by acting on the fauces. Received into the stomach, it stimulates this, and promotes digestion; and therefore is properly employed as a condiment with our animal food. If it be infused in water, and a portion of this infusion be taken with a large draught of warm water, it readily proves emetic, and may either be employed by itself to excite vomiting, or to assist the operation of other emetics. Infused in water, and taken into the stomach, it proves stimulant to the nervous system, and is thereby useful in palsy, and, if employed in large quantity, it proves heating to the whole body; and thereby it proves often useful in chronic rheumatism, whether arising from scurvy or other causes. Bergius has given us a particular method of exhibiting this root, which is, by cutting it down, without bruising, into small pieces; and these, if swallowed without chewing, may be taken down in large quantities, to that of a table-spoonful. And the author alleges, that, in this way, taken in the morning for a month together, this root has been extremely useful in arthritic cases; which, however, I suppose to have been of the rheumatic kind. It would seem, in this manner employed, analogous to the use of unbruised mustard-seed; it gives out in the stomach its subtle volatile parts, that stimulate considerably without inflaming. The matter of horse-radish, like the same matter of the other siliquose plants carried into the blood-vessels, passes readily into the kidneys, and proves a powerful diuretic, and is therefore useful in dropsy; and we need not say, that, in this manner, by promoting both urine and perspiration, it has been long known as one of the most powerful antiscorbutics."

Cochlearia hortensis. Lemon scurvy-grass. See *Cochlearia officinalis.*

Cochlearia officinalis. The systematic name of the lemon scurvy-grass. *Cochlearia hortensis; Cochlearia—foliis radicalibus cordato subrotundis; caulinis oblongis subsinuatis*, of Linnæus. This indigenous plant is cultivated in gardens for its medicinal qualities. Its expressed juice has been long considered as the most effectual of the scorbutic plants.

COCHLEATUS. Spiral, like the winding of a shell. Applied in botany to leaves, leguminous seeds, &c.; as *legumen cochleatum*, seen in *Medicago polymorpha*, and the seeds of the *Salsola.*

Cocho′ne. (From κοχαω, to turn round.) Galen explains this to be the juncture of the ischium, near the seat or breech; whence, says he, all the adjacent parts about the seat are called by the same name. Hesychius says, that *cochone* is the part of the spine which is adjacent to the os sacrum.

COCK. The male of the domestic fowl. See *Phasianus gallus.*

COCKBURN, William, was born in the latter part of the 17th century. After being some years physician to the navy, he settled in London; and soon distinguished himself so much, that he was admitted into the College, as well as the Royal Society, and made physician to King William. He published a "Treatise on Sea Diseases," which was often reprinted, and translated into French and German. He referred the scurvy principally to the diet of seamen, and considered fresh provisions as the chief remedy for it. He wrote also on Alvine Fluxes, on Gonorrhœa (which he contends may exist independent of syphilis,) and on the human Œconomy; which latter publication was much noticed at the time, but is since superseded by more accurate treatises.

CO′COS. (So called from the Portuguese *coco*, or *coquen*, the three holes at the end of the cocoa-nut shell, giving it the resemblance of a monkey's head. The name of a genus of plants in the Linnæan system. Class, *Monœcia*; Order, *Hexandria.*

Cocos butyracea. The systematic name of the plant which affords the palm oil; *Cocos—inermis, frondibus pennatis; foliolis simplicibus*, of Linnæus. The *oleum palmæ* is produced chiefly by bruising and dissolving the kernels of the fruit in water, without the aid of heat, by which the oil is separated, and rises to the surface, and on being washed two or three times, is rendered fit for use. When brought into this country, it is of the consistence of an ointment, and of an orange-yellow colour, with little taste, and of a strong, though not disagreeable smell. Its use is confined to external applications in pains, tumours, and sprains; but it appears to possess very little, if any, advantage over other bland oils.

Cocos nucifera. The systematic name of the plant, the fruit of which is the cocoa-nut. Within the nut is found a kernel, as pleasant as an almond, and also a large quantity of liquor resembling milk, which the Indians greedily drink before the fruit is ripe, it being then pleasant, but when the nut is matured, the liquor becomes sour. Some full-grown nuts will contain a pint or more of this milk, the frequent drinking of which seems to have no bad effects upon the Indians; yet Europeans should be cautious of making too free with it at first, for when Lionel Wafer was at a small island in the South Sea, where the tree grew in plenty, some of his men were so delighted with it, that at parting they were resolved to drink their fill, which they did; but their appetites had like to have cost them their lives, for though they were not drunk, yet they were so chilled and benumbed, that they could not stand, and were obliged to be carried aboard by those who had more prudence than themselves, and it was many days before they recovered. The shells of these nuts being hard, and capable of receiving a polish, they are often cut transversely, when, being mounted on stands, and having their edges silvered, or gilt, or otherwise ornamented, they serve the purpose of drinking-cups. The leaves of the tree are used for thatching, for brooms, baskets, and other utensils; and of the reticular web, growing at their base, the Indian women make cauls and aprons.

CO'CTION. (*Coctio*; from *coquo*, to boil.) Concoction. 1. The digestion of the food in the stomach. See *Digestion*.

2. A boiling or decoction. See *Decoction*.

3. It was formerly used in a medical sense, signifying that alteration, whatever it be, or however occasioned, which is made in the crude matter of a distemper, whereby it is either fitted for a discharge, or rendered harmless to the body. This is often brought about by nature; that is, by the vis vitæ, or the disposition or natural tendency of the matter itself, or else by proper remedies, which may so alter its bulk, figure, cohesion, or give it a particular determination, so as to prevent any farther ill effects, or drive it quite out of the body. And that time of a disease wherein this action is performing, is called its state of coction. It is now fallen into disuse.

Cocu'stu. The name for courbaril.

Coda'ga pala. See *Nerium antidysentericum*.

Codegella. A name given by the Italians to the carbuncle. See *Anthrax*.

Codoce'le. (From κωδια, a bulb, and κηλη, a tumour.) A bubo.

CŒCA'LIS. (From *cæcum*, the blind gut, through which it runs.) A vein, being a branch from the concave side of the vena mesaraica.

Cœ'la. (From κοιλος, hollow.) Applied to depression, or hollow parts on the surface of the body, as the hollow pits above, and sometimes below the eyes: the hollow parts at the bottom of the feet.

CŒ'LIA. (From κοιλος, hollow.) A cavity in any part of the body; as the belly, the womb, &c.

CŒ'LIAC. (*Cœliacus*, belonging to the belly, from κοιλια, the belly.) Appertaining to the belly.

Cœliac artery. *Arteria cœliaca.* The first branch given off from the aorta in the cavity of the abdomen. It sends branches to the diaphragm, stomach, liver, pylorus, duodenum, omentum, and spleen.

Cœliac passion. (From κοιλια, the belly.) *Cœlica chylosa; Cœlica lactea.* There are very great differences among physicians concerning the nature of this disease. Sauvages says it is a chronic flux, in which the aliment is discharged half digested. Dr. Cullen considers it as a species of diarrhœa, and mentions it in his third and fourth species, under the terms mucosa, chylosa, lactea; making the purulenta only symptomatic. See *Diarrhœa*. It is attended with great pains in the stomach, resembling the pricking of pins; rumbling and flatus in the intestines; white stools, because deprived of bile; while the patient becomes weak and lean.

CŒLIACA. *Cœliacus*; from κολαια, *alvus*, *venter*.) Dr. Good selects this name for the first class of diseases in his Nosology; diseases of the digestive function. It contains two orders, *Enterica* and *Splanchnica*.

Cœlo'ma. (From κοιλος, hollow.) An ulcer in the tunica cornea of the eye.

Cœlosto'mia. See *Coilostomia*.

CŒNOLO'GIA. (From κοινος, common, and λογος, discourse.) A consultation or common consideration of a disease, by two or more physicians.

Cœno'tes. (From κοινος, common.) The physicians of the methodic sect asserted that all diseases arose from relaxation, stricture, or a mixture of both. These were called *cænotes*, viz. what diseases have in common.

Cœru'leus lapis. The sulphate of copper. See *Cupri sulphas*.

CŒ'TE. (From κειμαι, to lie down.) A bed, or couch, for a sick person.

CO'FFEA. (From *kofuah*, a mixing together, Hebrew; so called from the pleasant potation which is made from its berry: others assert that the true name is *Caffe*, from *Caffa*, a province in South America, where the tree grows spontaneously in great abundance.) The name of a genus of plants in the Linnean system. Class, *Pentandria*; Order, *Monogynia*. The coffee-tree.

Coffea arabica. The plant which affords coffee. *Jasminum Arabicum; Choava.* Coffee is the seed of the *Coffea—floribus quinquefidis, dispermis*, of Linnæus.

The coffee-tree is cultivated in Arabia, Persia, the East Indies, the Isle of Bourbon, and several parts of America. Good Turkey coffee is by far the most salutary of all liquors drunk at meal-time. It possesses nervine and adstringent qualities, and may be drunk with advantage at all times, except when there is bile in the stomach. It is said to be a good antidote against an over-dose of opium, and to relieve obstinate spasmodic asthmas. For the latter purpose, the coffee ought to be of the best Mocco, newly burnt, and made very strong, immediately after grinding it. Sir John Pringle commonly ordered one ounce for a dose; which is to be repeated fresh, after the interval of a quarter or half an hour; and which he directed to be taken without milk or sugar.

Besides the peculiar bitter principle, which is described under the name *Caffein*, coffee contains several other vegetable products. According to Cadet, 64 parts of raw coffee consist of 8 gum, 1 resin, 1 extractive and bitter principle, 3.5 gallic acid, 0.14 albumen, 43.5 fibrous insoluble matter, and 6.86 loss. Hermann found in 1920 grains of

	Levant Coffee.	Mart. Coffee.
Resin,	74	68
Extractive,	320	310
Gum,	130	144
Fibrous matter,	1335	1386
Loss,	61	12
	1920	1920

The nature of the volatile fragrant principle developed in coffee by roasting, has not been ascertained. The Dutch in Surinam improve the flavour of their coffee by suspending bags of it, for two years, in a dry atmosphere. They never use new coffee.

If coffee be drunk warm within an hour after dinner, it is of singular use to those who have headache, from weakness in the stomach, contracted by sedentary habits, close attention, or accidental drunkenness. It is of service when the digestion is weak; and persons afflicted with the sick headache are much benefited by its use, in some instances, though this effect is by no means uniform. Coffee is often imitated by roasting rye with a few almonds.

COGAN, William, was born in Somersetshire, about the middle of the 16th century. He studied, and took the degree of bachelor in medicine at Oxford; soon after which he was appointed master of the school at Manchester, where he also practised in his profession till his death in 1607. He published a curious book, abounding in classical quotations, entitled "The Haven of Health," in which he strongly recommends temperance and exercise. There is added an account of the sweating sickness; and of a remarkable disorder, which prevailed at Oxford in July and August 1575, before he left it, by which he states, that in thirty-seven days "there died 510 persons, all men and no women."

COHE'SION. (*Cohæsio*; from *con*, and *hæreo*, to stick together.) *Vis cohæsionis*; *Vis adhæsionis*; *Vis attractionis*. That power by which the particles of bodies are held together. See *Attraction*.

Cohoba'tion. (A term invented by Paracelsus.) *Cohobatio*; *Cohobium*; *Cohoph*. The ancient chemists use this term to signify the distillation of a fluid poured afresh upon a substance of the same kind as that upon which it was before distilled, and repeating this operation several times, to make it more efficacious.

Co'hol. (*Cohol*, Hebrew.) Castellus says this word is used in Avicenna, to express dry collyria for the eyes, in fine powder.

Coi'lima. (From κοιλια, the bowels.) A sudden swelling of the belly from wind.

COILOSTO'MIA. (From κοιλος, hollow, and ϛομα, the mouth.) *Cælostomia*. A defect of speaking, from the palate, or through the nose, the voice being so obscured as to sound as if it proceeded from a cavern.

COINDICA'NTIA. (From *con*, and *indico*, to indicate.) Signs, or symptoms, are called coindicant, when, besides the usual incidental appearances, there occur others, as age, habit, season, &c.

Coi'ra. A name for catechu.

COITER, Volcher, was born at Groningen in 1534. After studying at the different universities in Italy, he attended as physician to the French army during one campaign, that he might have more opportunity for investigating human anatomy. He then settled at Nuremburg, where he continued till his death in 1576. He made considerable improvements in anatomy and surgery. He found that the brain had a motion communicated to it by the arteries; and that in some animals the organ might be removed without destroying life. He first described the corpora lutea in the ovaria; and noticed the order in which the parts of the chick are evolved. He described the frontal sinuses, and the organ of hearing, more accurately than any preceding author. He pointed out two muscles which depress the eye-brows, and two which perform the same office to the lips. He observed, that injuries to the brain are more dangerous when the dura mater remains entire; and therefore he boldly divided that membrane. He was also accustomed to pare down fungi arising from the brain. He published good plates of the cartilages, of the fœtal skeleton, and of those of various animals, &c.

CO'ITUS. (From *coeo*, to go together.) The conjunction of the male and female in the act of procreation.

CO'LA. (From κωλον, a joint.) The joints.

Colato'ria lactea. Astruc says they were formerly called glands, and are situated in the third and internal tunic of the uterus, and, that they are vesiculo-vascular bodies.

COLATO'RIUM. (From *colo*, to strain.) A strainer of any kind.

COLATU'RA. (From *colo*, to strain.) A filtered or strained liquor.

COLBATCH, John, was born in the latter part of the 17th century. He practised in London, first as a surgeon and apothecary, afterwards as a physician, and had considerable repute. He published several works: the first was "A New Light of Chirurgery," condemning the use of tents, and the injection of acrid substances into wounds; then a treatise, in which most diseases are ascribed to alkalescency, and acids strongly recommended; this in a subsequent publication he applied particularly to the gout; lastly, he highly extolled the misletoe as a remedy for epilepsy and other nervous diseases.

COLCHESTER. The name of a sea-port on the coast of Essex, near which is a mineral water, *aqua Colcestrensis*, which is of the bitter purging kind, similar to that of Epsom, but not so strong.

CO'LCHICUM. (From *Colchis*, a city of Armenia, where this plant is supposed to have been common.) 1. The name of a genus of plants in the Linnæan system. Class, *Hexandria*; Order, *Trigynia*. Meadow-saffron.

2. The pharmacopœial name of the meadow-saffron. See *Colchicum autumnale*.

Colchicum autumnale. The sytematic name of the common meadow-saffron. *Colchicum—foliis planis lanceolatis erectis*, of Linnæus. A native of England. The sensible qualities of the fresh root are very various, according to the place of growth and season of the year. In autumn it is almost inert, but in the beginning of summer highly acrid: hence some have found it to be a corrosive poison, whilst others have eaten it in considerable quantity, without experiencing any effect. When it is possessed of acrimony, this is of the same nature with that of garlic and some other plants, and is entirely destroyed by drying. The German physicians have celebrated its virtues as a diuretic, in hydrothorax, and other dropsies; and in France it continues to be a favourite remedy; but it is, nevertheless, in this country unsuccessful, or at best a very uncertain remedy. The expressed juice is used in Alsace, to destroy vermin in the heads of children. The officinal preparations of colchicum, are syrupus colchici autumnalis, Edin. Pharm. The oxymel colchici of the former London Pharmacopœia is now omitted, and the acetum colchici ordered in its room; as the honey may easily be added extemporaneously, if it be thought requisite. The active ingredient of this plant has lately been ascertained to be an alkali, possessing peculiar properties. See *Veratria.*

COLCHICUM ILLYRICUM. The plant supposed to afford the root called hermodactyl. See *Hermodactylus.*

COLCHICUM ZEYLANICUM. See *Zedoaria.*

COLCOTHAR. *Chalcitis; Colcothar vitrioli.* The brown-red oxide of iron, which remains after the distillation of the acid from sulphate of iron.

COLCOTHAR VITRIOLI. See *Colcothar.*

COLD. 1. A privation of heat. It is nothing positive, but somewhat of the negative kind. The human body contains within itself, as long as it is living, a principle of warmth: if any other body, being in contact with it, abstracts the heat with unusual rapidity, it is said to be cold; but if it carries off the heat more slowly than usual, or even communicates heat to our body, it is said to be hot.

2. A cold is a popular name also for a catarrh. See *Catarrhus.*

Cold Affusion. See *Affusion.*

COLE, WILLIAM, studied at Oxford, and took his degree there in 1666. After practising some time at Bristol, he came to London and distinguished himself by several publications on physiology and medicine, which however are too theoretical. The principal are on animal secretion, on apoplexy, on the cause of fever, on insensible perspiration, &c. He published also a case of epilepsy, cured, in his opinion by the misletoe.

CO'LES. (From καυλος, a stalk.) *Colis.* The penis.

COLEWORT. See *Brassica.*

CO'LICA. (From κωλον, colon, the name of one of the intestines.) The colic. The appellation of colic is commonly given to all pains in the abdomen, almost indiscriminately; but, from the different causes and circumstances of this disorder, it is differently denominated. When the pain is accompanied with a vomiting of bile, or with obstinate costiveness, it is called a *bilious colic;* if flatus causes the pain, that is, if attended with temporary distension, relieved by the discharge of wind, it takes the name of *flatulent* or *windy colic;* when accompanied with heat and inflammation, it takes the name of *inflammatory colic,* or *enteritis.* When this disease arises to a violent height, and is attended with obstinate costiveness, and an evacuation of fæces by the mouth, it is called *passio iliaca,* or iliac passion.

Dr. Cullen places this genus of disease in the class *neuroses* and order *spasmi;* and defines it pain of the abdomen, particularly round the umbilicus, attended with vomiting and costiveness. He enumerates seven species.

1. *Colica spasmodica,* with retraction of the navel, and spasm of the muscles of the belly.

2. *Colica pictonum.* This is called from the place where it is endemial, the Poictou, the Surinam, the Devonshire colic; from its victims, the plumbers' and the painters' colic: from its symptoms, the dry belly-ache, the nervous and spasmodic colic. It has been attributed to the poison of lead, and this is undoubtedly the cause, when it occurs to glaziers, painters, and those employed in lead works; but, though this is one, it is by no means the only cause. In Devonshire, it certainly more often arises from the early cyder, made of harsh, unripe fruit, and in the West Indies from new rum. The characteristics of this disease are, obstinate costiveness, with a vomiting of an acrid or porraceous bile, pains about the region of the navel, shooting from thence to each side with excessive violence, strong convulsive spasms in the intestines, and a tendency to a paralysis of the extremities. It is occasioned by a long-continued costiveness; by an accumulation of acrid bile; by cold applied either to the extremities, or to the belly itself; by a free use of unripe fruits, and by great irregularity in the mode of living. From its occurring frequently in Devonshire, and other cyder countries, it has been supposed to arise from an impregnation of lead received into the stomach; but this seems to be a mistake, as it is a very prevalent disease in the West Indies likewise, where no cyder is made, and where there is only a very small quantity of lead in the mills employed to extract the juice from the sugar-canes. One or other of the causes just enumerated, may justly be said always to give rise to this species of colic.

The disease comes on gradually, with a pain at the pit of the stomach, extending downwards to the intestines, accompanied with eructations, slight sickness at the stomach, thirst, anxiety, obstinate costiveness, and a quick contracted pulse. After a short time, the pains increase considerably in violence; the whole region of the belly is highly painful to the touch; the muscles of the abdomen are contracted into hard irregular knots or lumps; the intestines themselves exhibit symptoms of violent spasm, insomuch that a glister can hardly be injected, from the powerful contraction of the sphincter ani; and there is constant restlessness, with a frequent vomiting of an acrid or porraceous matter, but more particularly after taking either food or medicine.

Upon a farther increase of the symptoms, or their not being quickly alleviated, the spasms become more frequent, as well as violent; the costiveness proves invincible, and an inflammation of the intestines ensues, which soon destroys the patient by gangrene. In an advanced stage of the disease, it is no uncommon occurrence for dysuria to take place, in a very high degree.

The dry belly-ache is always attended with some degree of danger; but which is ever in proportion to the violence of the symptoms, and the duration of the disease. Even when it does not prove fatal, it is too apt to terminate in palsy, and to leave behind it contractions of the hands and feet, with an inability in their muscles to perform their office; and in this miserable state of existence, the patient lingers out many wretched years.

Dissections of this disease usually show the same morbid appearances as in common colic, only in a much higher degree; namely, irregular contractions and distentions of the intestines, often with marks of inflammation.

3. *Colica stercorea,* which happens from obstinate and long-continued costiveness.

4. *Colica accidentalis,* called also cholera sicca, from acrid undigested matters.

5. *Colica meconialis,* in infants, from a retention of meconium.

6. *Colica callosa,* with a sensation of a stricture in some part of the colon, and frequently of previous flatulence, gradually passing off; the habit costive, or fæces liquid, and in small quantity.

7. *Colica calculosa,* from calculi formed in the

intestines, attended with a fixed hardness in some part of the abdomen. It is distinguished by the previous discharge of calculi.

8. *Colica flatulentia*, may be added to these species. It is distinguished by a sudden fulness, with pain and constipation, relieved by a discharge of wind from the mouth, or anus.

The colic is distinguished from inflammation of the intestines by the pain being *wringing*, and not of a burning kind; by the *spasmodic contraction* of the abdominal muscles; by the *absence* or *trifling* degree of fever; by the *state* of the pulse, and by the *diminution* of pain upon pressure, which increases it in enteritis.

The flatulent and inflammatory colic are thus distinguished from each other:—In the flatulent colic, the pain comes on by fits, flies from one part of the bowels to another, and is much abated by a discharge of wind, either upwards or downwards; but in the inflammatory colic the pain remains equable, and fixed and settled in one spot; the vomitings are severe, and frequently bilious; the belly is obstinately bound, and the pulse quick and feverish.

The colic should be distinguished from a fit of the gravel; stones passing through the ureters; rheumatic pains in the muscles of the belly; a beginning dysentery; the blind piles; and from a stone passing through the gall-duct. Gravel in the kidneys produces often colic pains, not easily distinguishable; but when stones pass through the ureters, the testicle on that side is often retracted, the leg is benumbed, a pain shoots down the inside of the thigh; symptoms occasioned by the stone passing through the ureter over the spermatic chord, or the sacro-sciatic nerve. Rheumatic pains in the muscles of the belly rarely affect so accurately the umbilical region, but dart in various directions, to the chest, or to the pelvis, and are attended with soreness, not confined to the abdomen. A beginning dysentery differs little from colic. The pain from the blind piles is confined to the rectum: and that from a stone in the gall-duct, is felt in the pit of the stomach, occasionally shooting through the body to the back.

The treatment of this disease must vary according to its form: but the leading indications are, 1. To obviate inflammation. 2. To relax the spasm, and relieve the pain attending. 3. To remove local irritation, especially by evacuating the alvine contents. 4. By various prophylactic measures to guard against a relapse.

1. The chief danger arising from inflammation supervening, it may be prudent to anticipate this, where the habit and strength will allow, by taking away an adequate quantity of blood from the arm, or more generally by leeches to the abdomen, but especially where any sign of inflammation appears, this plan becomes necessary, followed by a hot bath, or fomentations, a blister to the abdomen, &c. as detailed under *enteritis*.

2. The means already noticed may serve to relax spasm also, though not requisite in slight cases, besides the various antispasmodic remedies, as æther, assafœtida, &c., likewise aromatics, or spirituous liquors, will often by their stimulus on the stomach afford relief in flatulent colic, though their use is sometimes hurtful; but by far the most powerful remedy is opium in adequate quantity, which is best regulated in severe attacks, by giving divided doses at short intervals till ease is obtained.

3. Local irritation may sometimes be relieved by chemical remedies, as antacids, particularly magnesia, &c.; but for the most part the evacuation of the intestines should be attempted, when the pain is relieved. To prepare for this, calomel may be given in conjunction with the opium, and when the patient has been some time at ease, this may be followed up by castor oil, sulphate of magnesia, or other mild laxative, repeated till the desired effect be produced; or where these do not presently operate, some more active cathartics, as the compound extract of colocynth, jalap, &c. should be tried. If the stomach be irritable, the effervescing saline draught may enable it to retain them; and clysters will often assist the articles taken by the mouth, particularly where there are indurated fæces. In very obstinate cases, an injection of tobacco smoke has often succeeded in procuring evacuations: also putting the feet for some time into cold water, or pouring this on the abdomen and lower extremities. Sometimes it has been necessary to remove fœcal accumulations mechanically per anum.

4. The great liability of this complaint to return renders it necessary for some time after carefully to regulate the diet, to attend to the state of the bowels, as well as of the liver, to avoid the several causes, especially cold, maintaining the functions of the skin by suitable clothing, exercise, &c. In the colica pictonum, stimulant aperients, as the peruvian balsam, mustard, &c. steadily persisted in, will mostly effect a complete cure; and mercury has been by some highly extolled; by others astringents, especially alum, though certainly somewhat objectionable, as liable to confine the bowels.

Colica accidentalis. Colic from crudities in the bowels.

Colica arteria sinistra. The lower mesenteric artery.

Colica arteria superior. The upper mesenteric artery.

Colica biliosa. Colic from excess of bile.

Colica calculosa. Colic from stony matters in the intestines.

Colica callosa. Colic from hardened and obstinate strictures.

Colica Damnoniorum. Colic peculiar to Devonshire. See *Colica*.

Colica febricosa. Colic with fever.

Colica flatulenta. Colic from wind.

Colica gravidarum. Colic in pregnant women.

Colica hysterica. Hysteric colic.

Colica lactantium. Colic peculiar to nurses.

Colica Lapsonica. Colic peculiar to Laplanders.

Colica meconialis. Colic from meconium in infants.

Colica mesenterica. Colic from diseased mesentery.

Colica nervosa. The nervous colic.

Colica pancreatica. Colic from diseased pancreas.

Colica phlogistica. Colic with inflammation.

Colica pictonum. See *Colica*.

Colica pituitosa. The spasmodic colic.

Colica plethorica. The inflammatory colic.

Colica plumbariorum. The colic of lead-workers.

Colica pulsatilis. The inflammatory colic.

Colica saturnina. The Devonshire colic. See *Colica*.

Colica scirrhosa. The colic from scirrhous tumours.

Colica spasmodica. The spasmodic colic.

Colica stercorea. Colic from retained fæces.

Colica vena. A branch of the upper mesenteric vein.

Colica vena recta. The vein of the colon.

Colica verminosa. The colic from worms.

CO′LICE. The colic.

COLIFO′RMIS. (From *cola*, a strainer, and *forma*, a likeness; so called from its having many perforations, like a strainer.) *Coliforme os.* A name formerly given to the ethmoid-bone.

Coli′phium. (From κωλον, a limb, and ιφι, strongly.) A kind of bread given to wrestlers. It was made of flour and bran together, and was thought to make men athletic.

Co′lis. See *Coles.*

COLLA′PSUS. (From *collabor*, to shrink down.) A wasting or shrinking of the body, or strength.

Collate′nna. A specific vulnerary.

Collatera′les. So Spigelius calls the erectores penis, from their collateral order of fibres.

Colle′tica. (From κολλα, glue.) Conglutinating medicines.

Colli′ciæ. (From *colligo*, to collect.) The union of the ducts, which convey the humours of the eyes from the puncta lachrymalia to the cavity of the nose.

COLLI′CULUM. (Diminutive of *collis*, a hill.) 1. A small eminence.

2. The nympha, or prominency, without the vagina of women.

COLLIGA′MEN. (From *colligo*, to tie together.) A ligament.

COLLINS, Samuel, was born in the early part of the 17th century. After studying at Cambridge and Oxford, he went to the Russian court as physician, and continued there nine years. On his return, he was made Fellow of the College of Physicians in London. He afterwards published a history of the Court of Russia, and in 1685 a system of anatomy, treating of the body of man, animals, and plants, with numerous plates. The comparative anatomy, to which Dr. Tyson greatly contributed, was much admired, though now superseded by other publications.

COLLIQUAME′NTUM. (From *colliqueo*, to melt.) A term first made use of by Dr. Harvey, in his application of it to the first rudiments of an embryo, in generation.

COLLI′QUATIVE. (*Colliquativus*, from *colliqueo*, to melt.) Any excessive evacuation is so called which melts down, as it were, the strength of the body: hence colliquative perspiration, colliquative diarrhœa, &c.

COLLI′SIO. (From *collido*, to beat together.) A contusion.

Co′llix. (From κολον, food.) A troch, or lozenge.

COLLOBO′MA. (From κολλαω, to glue together.) *Colobroma.* 1. The growing together of the eye-lids.

2. The want of any member of the body.

COLLO′DES. (From κολλα, glue.) Glutinous.

CO′LLUM. (From κωλον, a member, as being one of the chief; or diminutive of *columna*, as being the pillar and support of the head.) The neck. See *Neck.*

COLLUTION. *Collutio.* The washing of the mouth, or any other part.

COLLUTO′RIUM. (From *colluo*, to wash.) A gargarism or wash for the mouth.

COLLU′VIES. (From *colluo*, to cleanse.) Filth; Excrement. The discharge from an old ulcer.

CO′LLYRIS. (Κολλυρις. A little round cake; so called from its likeness to a cake.) A bump, or knob, which rises after a blow.

COLLY′RIUM. (From κωλυω, to check, and ῥους, a defluxion; because it stops the defluxion.) A medicine was formerly so called which was applied to check any discharge. The term is now only given to fluid applications for the eyes, or eye-waters.

Coloboma. See *Colloboma.*

Colobo′mata. In Celsus this word is expressed by curta. Both the words signify a deficiency in some part of the body, particularly the ears, lips, or alæ of the nostrils.

Coloca′sia. (From κολον, food, and καζω, to adorn; so called from its use as a food, and the custom of wearing its flowers in wreaths.) The faba Ægyptia. See *Nymphæa nelumbo.*

COLOCY′NTHIS. (From κωλον, the colon, and κινεω, to move; because of its great purging powers.) *Coloquinteda.* See *Cucumis colocynthis.*

COLO′MBO. See *Calumba.*

CO′LON. (*Colon, i.* neut.; Κωλον, quasi κοιλον; from κοιλος, hollow: so called from its capacity, or from its generally being found empty, and full of wind in dissection.) The greater portion of the large intestine is so called. It proceeds towards the liver, by the name of the *ascending portion of the colon;* and having reached the liver, forms a *transverse arch* across to the other side. The colon then descends, forming what is termed its *sigmoid flexure*, into the pelvis, where the gut is called rectum. See *Intestine.*

COLOPHO′NIA. (Κολοφωνια, the city from whence it was first brought.) Colophony. 1. The black resin which remains in the retort, after distilling the common resin with a strong fire.

2. Paracelsus seems to mean by it what is now prescribed by the name of *terebinthina cocta.*

3. The ancients, and particularly Galen, seemed to understand by it a soft kind of mastich, from *Chio*, probably the same as our *Chio* turpentine.

COLOPHONITE. Resinous garnet of Haüy and Jameson. A mineral of a blackish or yellowish brown, or orange-red colour, and a resino-adamantine lustre found in magnetic ironstone in Norway and in Ceylon.

COLOQUINTIDA. See *Cucumis colocynthis.*

COLORATUS. Coloured: applied to leaves, calyces, seeds, &c. to express any colour besides green, as in *Arum bicolor;* or to any part thereof when of another colour than green, as in *Amaranthus tricolor;* and to a *perianthium* when not of a green colour, as that of the *Gomphrena globosa:* and the seeds of *Chærophyllum aureum.*

COLO′STRUM. (From κολον, food, or κολλωμαι, to agglutinate; so called, either because it is the first food of the young, or from its being at that time peculiarly glutinous.) 1. The first milk in the breasts after delivery.

2. An emulsion made by the solution of turpentine with the yolk of an egg.

COLOT, Germain, a French surgeon of the 15th century, appears to have been the first of the profession who practised lithotomy, that operation having been previously in the hands of itinerant practitioners. He acquired great celebrity by his skill, and was much in favour with Lewis IX., who granted him a pension. Several of his descendants in succession enjoyed great reputation as lithotomists.

COLOT, Francis, the last of them, left a treatise, published in 1727, describing the method of operating with the greater apparatus, the invention whereof he ascribes to John de Romanis, an Italian physician, about two centuries before. But this has long been superseded by the lesser apparatus, which Mr. Sharp attributes to another French surgeon, Mons. Foubert.

COLOTOI′DES. (From κωλωτης, a lizard, and ειδος, likeness.) Variegated like the skin of a lizard. Hippocrates applied it to the excrements.

Coloured leaf. See *Leaf.*

COLPOCE′LE. (From κολπος, the vagina, and κηλη, a tumour.) A hernia forced into the vagina. See *Hernia vaginalis.*

COLPOPTO′SIS. (From κολπος, the vagina, and ϖιπτω, to fall down.) A bearing down of the vagina. See *Hernia vaginalis.*

COLT'S-FOOT. See *Tussilago.*

CO′LUBER. (*Quod colit umbram*, because it delighteth in the shade.) A genus of animals in the Linnæan arrangement, of which there are many species.

COLUBER BERUS. The systematic name of the viper, which possesses the power of forming a poisonous fluid in little bags near its teeth. The flesh is perfectly innocent, and often taken by the common people against the king's evil, and a variety of disorders of the skin. Experience evinces it to be an inefficacious substance.

COLUBRI′NA VIRGINIANA. See *Aristolochia serpentaria.*

COLUBRINUM LIGNUM. (*Colubrinus*; from *coluber*: so called from the snake-like contortions of its roots.) This species of snake-wood is brought from America. It is solid, ponderous, acrid, extremely bitter, and inodorous; its bark is of a ferruginous colour, covered with cineritious spots.

COLU′MBA. See *Calumba.*

COLUMBIC ACID. *Acidum Columbicum.* "The experiments of Hatchett have proved, that a peculiar mineral from Massachusetts, deposited in the British Museum, consisted of one part of oxide of iron, and somewhat more than three parts of a white coloured substance, possessing the properties of an acid. Its basis was metallic. Hence he named this Columbium, and the acid the Columbic. Dr. Wollaston, by very exact analytical comparisons, proved, that the acid of Hatchett was the oxide of the metal lately discovered in Sweden by Ekeberg, in the mineral yttrotantalite, and thence called tantalum. Dr. Wollaston's method of separating the acid from the mineral is peculiarly elegant. One part of tantalite, five parts of carbonate of potassa, and two parts of borax, are fused together in a platina crucible. The mass, after being softened in water, is acted on by muriatic acid. The iron and manganese dissolve, while the columbic acid remains at the bottom. It is in the form of a white powder, which is insoluble in nitric and sulphuric acids, but partially in muriatic. It forms with barytes an insoluble salt, of which the proportions, according to Berzelius, are 24.4 acid, and 9.75 barytes. By oxidizing a portion of the revived tantalum or columbium, Berzelius concludes the composition of the acid to be 100 metal and 5.485 oxygen."

COLUMBINE. See *Aquilegia.*

COLU′MBIUM. Hatchett describes the ore from which this metal is obtained, as being of a dark brownish-grey externally, and more inclining to an iron-grey internally; the longitudinal fracture he found lamellated, and the cross fracture had a fine grain. Its lustre was vitreous, slightly inclining, in some parts, to metallic; moderately hard and very brittle. The colour of the streak, or powder, was dark chocolate-brown. "If the oxide of columbium, described under *Columbic acid*, be mixed with charcoal, and exposed to a violent heat in a charcoal crucible, the metal columbium will be obtained. It has a dark grey colour; and when newly abraded, the lustre nearly of iron. Its sp. gr. when in agglutinated particles, was found by Dr. Wollaston to be 5.61. These metallic grains scratch glass, and are easily pulverized. Neither nitric, muriatic, nor nitro-muriatic acid, produces any change in this metal, though digested on it for several days. It has been alloyed with iron and tungsten."

COLUMBO′BE. See *Calumba.*

COLUME′LLA. (Diminutive of *columna*, a column.) 1. A column or little pillar.

2. The central column, or filament, which unites the partitions of the capsule of plants. The seeds are usually attached to it. See also *Uvula*, and *Clitoris.*

COLUMELLA′RIS. (From *columella*, a little column.) A name of the dens caninus.

COLU′MNA. A column, or pillar. Many parts of the body, which in their shape or office resemble columns, are so named; as columnæ carneæ, &c.

COLUMNA CARNEA. See *Heart.*

COLUMNA′NASI. The lowest and fleshy part of the nose, which forms a part of the septum.

COLUMNA ORIS. The uvula.

COLUMNIFERÆ. The name of an order of plants in Linnæus's Fragments of a Natural Method, consisting of plants, the stamina and pistil of which have the appearance of a pillar in the centre of the flower.

COLUMNULA. A little column. The name given by botanists to the filament which passes through the middle of the capsule of frondose mosses, to which the seeds are connected; also called *Sphrongidium.*

COLU′RIUM. (Παρα το κολλαν τον ρουν: because it prevents a defluxion.) A tent to thrust into a sore, to prevent a defluxion of humours.

CO′MA. (From κω, or κεω, to lie down.)

In pathology, a propensity to sleep. This word anciently meant any total suppression of the powers of sense; but now it means a lethargic drowsiness.

In botany, 1. A fasciculus of leaves on the top of a stem or stipe. It is said to be,

a. *Foliose*, when formed of leaves; as in *Bromelia ananas.*

b. *Frondose*, when proceeding from the frond at the apex of the stipe; as in *Palms.*

c. *Bracteal*, formed of floral leaves; as in *Lavendula stæchas.*

2. Gœrtner applies this term to the feathery crown of seeds furnished with a capsule.

COMA SOMNOLENTUM. Is when the patient continues in a profound sleep; and, when awakened, immediately relapses, without being able to keep open his eyes.

COMA VIGIL. A disease where the patients are continually inclined to sleep, but cannot.

CO′MATA. (*Comata*, the plural of *coma.*) An order of the class *Neuroses* of Cullen's Nosology, embracing diseases that are characterised by a diminution of the powers of voluntary motion, with sleep, or the senses impaired.

COMATOSE. Having a strong propensity to sleep.

COMBINATION. The intimate union of the particles of different substances by chemical attraction, so as to form a compound possessed of new and peculiar properties.

COMBUSTIBLE. Having the property of burning. See *Combustion.*

COMBU'STIO. (From *comburo*, to burn.) A burn, or scald. See *Burn.*

COMBUSTION. (*Combustio*; from *comburo*, to burn.) Burning. Among the various operations of chemistry, none acts a more conspicuous part than combustion; and in proportion to its utility in the science, the necessity of thoroughly investigating its nature and mode of action, becomes more obvious to the philosophical chemist.

Lavoisier's Theory of Combustion.

Lavoisier's theory of combustion is founded upon the absorption of oxygen by a combustible body.

Taking this for granted, it follows that combustion is only the play of affinity between oxygen, the matter of heat, and a combustible body.

When an *incombustible* body (a brick for instance) is heated, it undergoes no change, except an augmentation of bulk and temperature; and when left to itself, it soon regains its former state. But when a *combustible* body is heated to a certain degree, in the open air, it becomes on a sudden intensely hot, and at last emits a copious stream of caloric and light to the surrounding bodies. During this emission, the burning body gradually wastes away. It either disappears entirely, or its physical properties become totally altered. The principal change it suffers, is that of being no longer capable of combustion. If either of these phenomena, namely, the emission of heat and light, and the waste of substance, be wanting, we do not say that a body is undergoing combustion, or that it is burning. It follows, therefore, that every theory of combustion ought to explain the following facts:

1. Why a burning body is consumed, and its individuality destroyed.
2. Why, during the progress of this alteration, heat and light are emitted.

For the elucidation of these objects, Lavoisier's theory has laid down the following laws:

1. Combustion cannot take place without the presence of oxygen, and is more rapid in proportion to the quantity of this agent, in contact with the inflamed body.
2. In every act of combustion, the oxygen present is consumed.
3. The weight of the products of every body after combustion, corresponds with the weight of the body before combustion, *plus* that of the oxygen consumed.
4. The oxygen absorbed by the combustible body may be recovered from the compound formed, and the weight regained will be equal to the weight which disappeared during the combustion.
5. In every instance of combustion, light and heat, or fire, are liberated.
6. In a limited quantity of air, only a certain quantity of the combustible body can be burnt.
7. The air, wherein a body has been burnt, is rendered unfit for continuing combustion, or supporting animal life.

Though every case of combustion requires that light and heat should be evolved, yet this process proceeds very differently in different circumstances; hence the terms *ignition*, or glowing heat; *inflammation*, or accension; and *detonation*, or explosion.

Ignition takes place when the combustible body is not in an aëriform state.

Charcoal, pyrophorous, &c. furnish instances of this kind.

It seems as if the phenomenon of glowing was peculiar to those bodies which require a considerable quantity of caloric, to become converted into the gaseous state.

The disengagement of caloric and light is rendered more evident to the senses in the act of

Inflammation, or accension. Here the combustible substances are more easily converted into an elastic or aëriform state. Flame, therefore, consists of the inflammable matter in the act of combustion in the gaseous state. When all circumstances are favourable to the complete combustion of the products, the flame is perfect; if this is not the case, part of the combustible body, capable of being converted into the gaseous state, passes through the luminous flame unburnt, and exhibits the appearance of smoke. Soot, therefore, always indicates an imperfect combustion. Hence a common lamp smokes, an Argand's lamp yields no smoke.

This degree of combustion is very accurately exemplified in the

Flame of candles.—When a candle is first lighted, which must be done by the application of actual flame, a degree of heat is given to the wick, sufficient to destroy the affinity of its constituent parts; part of the tallow is instantly melted, volatilised, and burnt. As this is destroyed by combustion, another portion melts, rises, and supplies its place, and undergoes a like change. In this way combustion is maintained. The tallow is liquified as it comes into the vicinity of the flame, and is, by the capillary attraction of the wick, drawn up to supply the place of what is burnt; the unmelted tallow, by this means, forms a kind of cup.

The congeries of capillary tubes which form the wick is black, because the charcoal of the cotton becomes predominant, the circumambient air is defended by the flame from oxidising it; it therefore remains, for a considerable time, in its natural state; but when the wick, by the continual consumption of tallow, becomes too long to support itself in a perpendicular position, its upper extremity projects nearly out of the cone of the flame, and there forms a support for an accumulation of soot, which is produced by the imperfect combustion. A candle, in this situation, affords scarcely one-tenth of the light it can otherwise give, and tallow candles, on this account, require continual snuffing.

But if the candle be made of wax, the wick does not long occupy its place in the middle of the flame; its thinness makes it bend on one side, when its length is too great for its verticle position; its extremity comes then into contact with the air, and is completely burnt, or decomposed, except so much of it as is defended by the continual afflux of the melted wax. This small wick, therefore, performs the office of snuffing itself. The difficult fusibility of wax enables us to use a thinner wick for it than can be used for tallow, which is more fusible. But wax being a substance which contains much more oxygen than tallow, or oil, the light it affords is not so luminous.

Detonation is an instantaneous combustion, accompanied with a loud report; it takes place in general when the compounds resulting from the union of two or more bodies, occupy much more or less space than the substances did before their union; a great impulse is therefore given to the surrounding air, or else a vacuum is formed, and the air rushing in from all sides to fill it up is the cause of the report.

A mixture of oxygen and hydrogen gases detonates very loud. Gunpowder, fulminating gold, silver and mercury; oxygenated muriate of potassa; and various other explosive compounds, are capable of producing very loud detonations.

With respect to the disengagement of light and caloric.

By the older chemists, it was universally supposed that the light and heat emitted during combustion, proceeded from the inflammable body; and this opinion would indeed appear unquestionable, while the composition of the atmosphere was imperfectly known. The burning body appeared luminous and felt hot, and no other agent was supposed to be concerned; the conclusion that the light and heat were evolved from the burning substance, was, therefore, unavoidable. But when the nature of the atmosphere was ascertained, and when it became evident that part of the air was absorbed during combustion, the former conclusion fell to the ground; for when two bodies exert a mutual action on each other, it becomes *à priori* equally probable that the products may be derived from either of them; consequently, the light and heat evolved might proceed either from the one or the other. Whether they proceed from the atmosphere, or from the combustible body, they must be separated at the part where the combination takes place; that is, upon the surface of the burning body itself; and consequently it appeared luminous and heated, while the air being invisible escaped observation.

When the laws of heat became known, at least when it was ascertained that bodies contain at the same temperature, and in equal quantities, either of mass or bulk, unequal quantities of heat, the conclusion became probable, that the caloric evolved in combustion proceeded rather from the oxygen gas of the atmosphere, than from the combustible body; since the former contains a much larger quantity than the latter. The caloric evolved was therefore supposed to be derived from the *condensation* of the oxygen gas in the new combination into which it entered.

Though *approaching* to the truth, this explanation is not strictly true. It is not merely from the oxygen gas being *condensed* that the caloric is evolved, because, in many cases of combustion, the product still exists in the gaseous state, and in others, the quantity of caloric evolved bears no proportion to the degree of condensation. Philosophers ascribed this to a change of capacity; for, in different bodies, the difference in the proportion of the capacities before and after combustion, is by no means uniform; and hence the difference in the quantities of caloric extricated in various cases of combustion.

This being premised, it remains to explain the origin of the light emitted during combustion; for although we take it for granted that the caloric is evolved from the oxygen gas, we cannot infer that the light has the same origin.

It is very probable that light is a constituent part of inflammable bodies; for it is frequently evolved in combinations when the oxygen is merely *transferred* from one inflammable substance to another. In those cases it must proceed from the inflammable body. The accension of oils by the affusion of acids, the combustion of metals in the same way, furnish instances of the kind.

It seems, therefore, probable that the light is derived from the inflammable substance; and that the oxygen, combining with the bases of these substances, disengages the light.

It may be concluded then, that light enters into the composition of all combustible bodies; but as we are unable to separate the light, so as to obtain these bodies pure, we treat of them as simple bodies.

According to this theory, the combustion of phosphorous in oxygen gas, is therefore, the effect of a double affinity. The basis of the oxygen gas unites with the phosphorus, to form phosphoric acid; and the light disengaged from the phosphorus, together with the heat of the oxygen gas, produces the vivid flame.

The quantity of light emitted by different bodies is supposed to depend on the quantity contained in them, and on the proportion in which it is united to caloric.

Such is the theory of combustion of Lavoisier, modified by Gren, Leonardi, and Richter.

Thomson's Theory of Combustion.

Though the preceding theory of combustion is simple and beautiful, it appears, from what we are now going to state, to be by no means completely satisfactory.

It has misled chemists, by confining the term combustion to the act of oxygenation, and considering that all bodies, during their combustion, combine with oxygen, without at the same time recollecting that this latter effect may take place without any of the phenomena usually attendant on combustion; and that, though certainly all combustion presupposes the combination of oxygen with a base, yet this combination may be, and repeatedly is, effected where no combustion can possibly take place. Nothing can be more evident than the difference which, in numberless instances, prevails between the act of oxygenation in bodies and that of combustion, inasmuch as neither the phenomena attending on, nor the results arising from them, are the same. That a distinction therefore should be made between these processes is obvious; and it is on this account that Dr. Thomson has offered a theory, which considers this subject in a new point of view, and which bids fair to enable us to estimate the phenomena of combustion much better than has hitherto been done.

According to Dr. Thomson's theory, all the bodies concerned in combustion are either. 1. *Combustibles.*—2. *Supporters of combustion.*—3. *Incombustibles.*

I. COMBUSTIBLE BODIES are those substances which are said, in common language, to *burn*. During the combustion, they appear to emit light and heat, and, at the same time, gradually waste away. When this change has reached its *maximum*, the process of combustion is at an end.

The class of combustibles is very numerous; but all the bodies belonging to it may be subdivided into three sets, namely:

1. Simple combustibles. 2. Compound combustibles. 3. Combustible oxides, &c.

Simple Combustibles.

1. Sulphur.
2. Phosphorus.
3. Diamond, or Carbon.
4. Hydrogen gas.
5. All the metals.
6. Boron.

Compound Combustibles.

The *compound combustibles* consist of compounds, formed by the simple combustibles uniting together, and are of course much more numerous than the simple combustibles. They may be arranged under the five following heads:

1. Sulphurets.
2. Phosphurets.
3. Carburets.
4. Alloys.
5. Sulphuretted, phosphuretted, and carburetted hydrogen.

The *combustible oxides* are either simple, having a single base, or compound, having more than one base. All the simple combustible oxides are by combustion converted into acids.

The compound combustible oxides are by far the most numerous.

II. The SUPPORTERS OF COMBUSTION are bodies which are not of themselves, strictly speaking, capable of undergoing combustion, but which are absolutely necessary for the process; for no combustible body can burn unless some one or other of them be present. Whenever they are excluded, combustion ceases. All the supporters of combustion known at present are oxygen, chlorine, iodine, and the compounds which these form with each other, and with azote.

There are indeed certain substances besides these, which possess nearly the same properties; these shall be afterwards enumerated under the title of *partial supporters.*

III. The INCOMBUSTIBLE BODIES are neither capable of undergoing combustion themselves, nor of supporting the combustion of those bodies that are; they are therefore not immediately connected with combustion; though most of them appear to be the results of that process. Azot, the alkalies, earths, &c. come under this division.

Some of the alkalies and earths possess certain properties in common with combustibles, and are capable of exhibiting phenomena somewhat analogous to combustion; which will be described afterwards under the title of *semi-combustion.*

In every case of combustion, there must therefore be present a *combustible* body, and a *supporter* of combustion. During combustion, the combustible always unites with the supporter. *It is this combination which occasions the apparent waste and alteration of the combustible.* The new compound thus formed is a *product of combustion.* Every product of combustion is either, 1. *an acid*, or 2. *an oxide*, &c. It is true, indeed, that other bodies sometimes make their appearance during combustion, but these will be found, upon examination, not to be products, nor to have undergone combustion.

Thus one of the two characteristic marks which distinguish combustion, namely, the apparent *waste and alteration of the combustible body*, has been fully explained. For the explanation of it we are indebted to Lavoisier, as stated before.

But though the combination of the combustible with oxygen, or other supporter, be a constant part of combustion, yet the facility with which combustibles burn is not proportional to their apparent affinity for oxygen.

Phosphorus, for instance, burns more readily than charcoal; yet charcoal is capable of abstracting oxygen from phosphorus, and of course has a greater affinity for it. Some of the combustible oxides take fire more readily than some of the simple combustibles; alkohol, æther, and oils, are exceedingly combustible, whereas all the metals require very high temperatures when the supporter is air.

This greater combustibility of combustible oxides is probably owing to the weaker affinity by which their particles are united. Hence they are more easily separated than homogeneous particles, and of course combine more readily with oxygen; those simple combustibles which melt easily, or which are in the state of lastic fluids, are also very combustible, because the cohesion between their particles is easily overcome.

It is owing to the same inferiority in the cohesion of heterogeneous particles, that some of the compound supporters occasion combustion in circumstances when the combustibles would not be acted on by simple supporters.

Thus phosphorus burns in air at the common temperature; but it does not burn in oxygen gas, unless its temperature be raised. Thus also oils burn rapidly when mixed with nitric acid. Nitrous gas and nitrous oxide constitute exceptions to this rule.

None of the *products* of combustion are combustible, according to the definition of combustion here given. This want of combustibility is not owing to their being saturated with oxygen; for several of them are capable of combining with an *additional dose* of it. But, during this combination, no caloric or light is ever emitted; and the compound formed differs essentially from a *product* of combustion; for by this additional dose of oxygen, the *product* is converted into a *supporter. Hence we see that combustion ought not to be confounded with the combination of a body with oxygen*, as was done formerly.

Combustion, indeed, cannot take place without the combination of oxygen or other supporter; but oxygen may combine with bodies in different proportions without the phenomena of combustion; and the *product obtained* by combustion is capable of becoming converted into a *supporter* of *combustion;* for instance, if lead be melted, and kept so for some time, it becomes covered with a grey pellicle, or *oxide of lead*, a product consisting of oxygen and lead; but if this oxide is suffered to be heated longer, it absorbs an additional quantity of oxygen, and becomes converted into a yellow powder, called *yellow oxide of lead.* If this yellow oxide be again exposed to heat, it absorbs still more oxygen, and becomes converted into *red oxide of lead.* When the *supporters* thus formed by the combination of oxygen with *products*, are made to support combustion, they do not lose all their oxygen, but only the additional dose which constituted them supporters. Of course they are again reduced to their original state of products of combustion. Hence it follows, that they owe their properties as supporters, not to the *whole* of the oxygen which they contain, but to the *additional dose* which constituted them supporters. We may therefore call them *partial supporters;* indicating by the term, that part only of their oxygen is capable of supporting combustion, and not the whole.

All the partial supporters with which we are acquainted, contain a metallic basis; for metallic oxides are the only products at present known, capable of combining with an additional dose of oxygen. It is a circumstance highly deserving attention, that when metals are capable of combining with several doses of oxygen, the product, or oxide formed by combustion is seldom or never that which contains a *maximum* of oxygen.

Thus it is evident that several of the products of combustion are capable of combining with oxygen. *The incombustibility of products, therefore, is not owing to their want of affinity for oxygen*, but to some other cause.

No product of combustion is capable of *supporting* combustion. This is not occasioned by any want of affinity to combustible bodies; for several of them are capable of combining with an additional dose of their basis. But by this combination, they *lose* their properties as products, and are converted into *combustibles.* The process, therefore, differs essentially from combustion. Thus phosphoric acid, a product of combustion, is capable of combining with an additional dose of phosphorus, and forming *phosphorous* acid, a combustible body. When this last acid is heated in contact with a supporter, it undergoes combustion; but it is only the additional dose of the combustible, which burns, and the whole is converted into phosphoric acid. Hence we see that it is not the whole basis of these compounds which is combustible, but merely the additional dose. The compounds, therefore formed by the union of a product and combustible, may be termed *partial combustibles;* indicating by the name, that a part only of the base is capable of undergoing combustion. Since the products of combustion are capable of combining with oxygen, but never exhibit the phenomena of combustion, except when they are in the state of partial combustibles, combustible bodies must contain a substance which they lose in burning, and to which they owe their combustibility; for, after they have lost it, they unite to oxygen *without* exhibiting the phenomena of combustion.

Though the products of combustion are not capable of supporting combustion, they not unfrequently part with their oxygen just as supporters do, give it out to combustibles, and convert them into products; but during this process, no heat nor light is ever evolved. Water, for instance, gives out its oxygen to iron, and converts it into the *black oxide*, a product. Thus we see that the oxygen of products is capable of converting combustibles into products, just as the oxygen of supporters; but during the combination of the last only, are heat and light emitted. The oxygen of supporters then contains something which the oxygen of products wants.

Whenever the whole of the oxygen is abstracted from products, the combustibility of their base is restored as completely as before combustion; but no substance is capable of abstracting the whole of the oxygen, except a *combustible*, or a *partial combustible*. Water, for instance, is a product of combustion, whose base is hydrogen. To restore the combustibility of the hydrogen, we have only to mix water with iron or zinc filings, and an acid; the metal is oxidized, and the hydrogen gas is evolved as combustible as ever. But no substance, except a combustible, is capable of separating hydrogen gas from water, by combining with its oxygen. Thus we see that combustibles are capable of restoring the combustibility of the bases of products; but they themselves lose their combustibility by the process, and are converted into products. Combustibility, therefore, may be thrown at pleasure from one body to another.

From these facts it is obvious, that the products of combustion may be formed without combustion; but in these cases a new combustible is always evolved. The process is merely an interchange of combustibility; for the combustible is converted into a product only by means of a product. Both the oxygen and the base of the product having undergone combustion, have lost something which is essential to combustion. The process is merely a double decomposition. The product yields its oxygen to the combustible, while at the same time the combustible gives out something to the base of the product; the combustibility of that base then is restored by the loss of its oxygen, and by the restoration of something which it receives from the other combustible thus converted into a product.

There is indeed another method of forming the products of combustion without actual combustion in certain cases; but the phenomena are much more complicated. This method is to expose them to the action of some of the supporters dissolved in water; especially nitric acid. Thus most of the metallic oxides may be formed without combustion by the action of that acid on the metals. But, in that case, a new supporter is always evolved, namely, nitrous gas; ammonia, a new combustible, is also usually formed; and, not unfrequently, the *product* is converted into a *partial supporter*.

No *supporter* can be produced by combustion, or by any equivalent process. As several of the supporters consist of oxygen combined with a base, it follows as a consequence that oxygen may combine with a base without losing that ingredient, which occasions combustion. The act of combination of oxygen with a base, therefore, is by no means the same with combustion. If we take a view of the different supporters, we shall find that all of them which can be obtained artificially are procured either from other supporters, or by the agency of electricity.

I. OXYGEN GAS may be procured from nitric acid, and from several of the partial supporters, as the black oxide of manganese, the red oxides of lead and of mercury. The action of heat is always necessary; but the process is very different from combustion.

II. AIR, as far as is known at present, cannot be formed artificially. The gas, indeed, which comes over during part of the usual distillation of nitrate of potassa and sulphuric acid, to obtain nitric acid, resembles air very closely. But it is obtained from a supporter.

III. NITROUS OXIDE has hitherto been only procured from nitrous gas and nitric acid, (in nitrate of ammonia,) both of which are supporters.

IV. NITROUS GAS can only be procured by the decomposition of nitric acid, a supporter.

V. OXYMURIATIC ACID, or Chlorine, can be formed by the action of muriatic acid on the black oxide of manganese, the red oxides of lead, iron, or mercury; all of which are partial supporters.

VI. NITRIC ACID is formed spontaneously upon the surface of the earth, by processes with which we are but imperfectly acquainted; but which certainly have no resemblance to combustion. Its oxygen is probably furnished by the *air*, which is a supporter; at least, it has been observed, that nitrogen and oxygen, at high temperatures, are capable of forming nitric acid.

This formation of nitric acid by means of electricity, has been considered as a combustion, but for what reason it is not easy to say: the substance acted upon is not a combustible with a supporter, but a supporter alone. Electricity is so far from being equivalent to combustion, that it sometimes acts in a manner diametrically opposite; *unburning*, if we may use the expression, a substance which has already undergone combustion, and converting a *product* into a *combustible* and a *supporter*. Thus it decomposes water, and converts it into oxygen and hydrogen gas; therefore it must be capable of supplying the substances which the oxygen and combustible lose when they combine by combustion, and form a product.

Several of the supporters and partial supporters are capable of combining with combustibles, without undergoing decomposition, or exhibiting the phenomena of combustion. In this manner, the yellow oxide of gold combines with ammonia; the red oxide of mercury with oxalic acid; and oxymuriatic acid with ammonia. Thus also nitrate of potassa may be combined, or at least intimately mixed with several combustible bodies, as in gun-powder, fulminating powder, &c. In all these compounds, the oxygen of the supporter and the combustible retain the ingredients which render them susceptible of combustion; hence the compound is still combustible. And in consequence of the intimate combination of the component parts, the least alteration is apt to destroy the equilibrium which subsists between them; the consequence is, combustion and the formation of a new compound. Hence these compounds burn with amazing facility, not only when heated, but when triturated, or struck smartly with a hammer. They have therefore received the name of *detonating* or *fulminating* bodies. Thus we have fulminating gold, fulminating mercury, fulminating powder, &c.

Such are the properties of the combustibles, the supporters, and the products; and such the phenomena which they exhibit when made to act upon each other.

If we compare together the *supporters* and the *products*, we shall find that they resemble each other in many respects. Both of them contain oxygen, or other supporter, as an essential constituent part; both are capable of converting combustibles into products; and several of both combine with combustibles and with additional doses of oxygen. But they differ from each other in their effects on combustibles. The former only produce combustion; whereas the products convert combustibles into products without combustion. Now, as the ultimate change produced upon combustibles by both these sets of bodies is the same, and as the substance which combines with the combustibles is in both cases the same, oxygen, for instance, we must conclude that this oxygen in the supporters contains something which the oxygen of the products wants, something which separates during the passage of the oxygen from the product to the combustible, and occasions the combustion, or emission of fire, which accompanies this passage. The oxygen of supporters then contains some ingredient which the oxygen of products wants. Many circumstances concur to render it probable that this ingredient is *caloric.*

The *combustibles* and the *products* also resemble each other. Both of them contain the same or a similar base; both frequently combine with combustibles, and likewise with oxygen; but they differ essentially in the phenomena which accompany their combination with oxygen. In the one case, *fire is emitted;* in the other, not. If we recollect that no substance but a combustible is capable of restoring combustibility to the base of a product, and that at its doing so it always loses its own combustibility; and if we recollect farther, that the base of a product does not exhibit the phenomena of combustion even when it combines with oxygen, we cannot avoid concluding, that all combustibles contain an ingredient which they lose when converted into products, and that this loss contributes to the fire which makes its appearance during the conversion. Many circumstances contribute to render it probable that this ingredient is *light.*

If we suppose that the oxygen of supporters contains caloric as an essential ingredient, and that light is a component part of all combustibles, the phenomena of combustion above enumerated, numerous and intricate as they are, admit of an easy and obvious explanation. The component parts of the oxygen of supporters are two; namely, 1. a base, 2. caloric. The component parts of combustibles are likewise two; namely, 1. a base, 2. light. During combustion, the base of the oxygen combines with the base of the combustible, and forms the product; while, at the same time, the caloric of the oxygen combines with the light of the combustible, and the compound flies off in the form of fire. Thus combustion is a double decomposition; the oxygen and combustible divide themselves each into two portions, which combine in pairs; the one compound is the *product,* and the other the *fire,* which escapes.

Hence the reason that the oxygen of products is unfit for combustion. It wants its caloric. Hence the reason that combustion does not take place when oxygen combines with products, or with the base of supporters. These bodies contain no light. The caloric of the oxygen of course is not separated, and no fire appears. And this oxygen still retaining its caloric, is capable of producing combustion whenever a body is presented which contains light, and whose base has an affinity for oxygen. Hence also the reason why a combustible alone can restore combustibility to the base of a product. In all such cases, a double decomposition takes place. The oxygen of the product combines with the base of the combustible, while the light of the combustible combines with the base of the product.

But the application of this theory to all the different phenomena described above, is so obvious, that it is needless to give any more examples. Let us rather inquire, with the author, into the evidences which can be brought forward in its support.

As caloric and light are always emitted during combustion, it follows that they must have previously existed in the combustible, the supporter, or in both.

That the oxygen of the supporters contains either one or both of these substances, follows incontrovertibly from a fact already mentioned, namely, that the oxygen of products will not support combustion, while that of supporters will. Hence the oxygen of supporters must contain something which the oxygen of the products wants, and this something must be caloric, or light, or both.

That the oxygen of some of the supporters at least contains caloric, as an ingredient, has been proved, in a satisfactory manner, by the experiments of Crawford, Lavoisier, and La Place. Thus the temperature of hot-blooded animals is maintained by the decomposition of *air.* Now if the oxygen of one supporter contains caloric, the same ingredient must exist in the oxygen of every supporter, because all of them are obviously in the same state. Hence we conclude that the oxygen of every supporter contains caloric as an essential ingredient.

The light emitted during combustion must either proceed from the combustible or the supporter. That it proceeds from the combustible, must appear pretty obvious, if we recollect that the colour of the light emitted during combustion varies, and that this variation usually depends, not upon the supporter, but upon the combustible. Thus charcoal burns with a red flame, sulphur with a blue or violet, zinc with a greenish-white, &c.

The formation of combustibles in plants, obviously requires the presence and agency of light. The leaves of plants emit oxygen gas, when exposed to the sun's rays, but never in the shade, or in the dark.

Besides vegetation, we are acquainted with two other methods of *unburning* products, or of converting them into products and combustibles, by exposing them, in certain circumstances, to the agency of *fire,* or of *electricity.* The oxides of gold, mercury, &c. when heated to redness, are decomposed, oxygen gas is emitted, and the pure metal remains behind. In this case, the necessary caloric and light must be furnished by the fire; a circumstance which explains why such reductions always require a red heat. When carbonic acid is made to pass repeatedly over red-hot charcoal, it combines with a portion of charcoal, and is converted into gaseous oxide of carbon. If this gas be a combustible oxide, the base of the carbonic acid and its oxygen must have been supplied with light and caloric from the fire; but if it be a *partial combustible,* it is merely a compound of carbonic acid and charcoal: which of the two it is, remains still to be ascertained.

Electricity decomposes water, and converts it into oxygen gas and hydrogen gas; it must, therefore, supply the heat and the light which these bodies lost when converted into a product.

These facts, together with the exact correspondence of the theory given above with the phenomena of combustion, render it so probable, that Dr. Thompson has ventured to propose it as an additional step towards a full explanation of the theory of combustion. Every additional experiment has served to confirm it more and more. It even throws light upon the curious experiments of the accension of metals with sulphur, which succeed *in vacuo*, under mercury, in nitrogen gas, &c.

Dr. Thompson has noticed, that the same emission of caloric and light, or of *fire*, takes place when melted sulphur is made to combine with potassa, or with lime, in a crucible or glass tube, and likewise when melted phosphorus is made to combine with lime heated to redness. He supposes that, in all probability, barytes and strontia exhibit the same phenomenon when combined with melted sulphur or phosphorus; and perhaps some of the metals when combined with phosphorus.

The phenomena Dr. Thompson explains thus:—The sulphur and phosphorus are in the melted state, and therefore contain caloric as an ingredient; the alkalies, earths, and metals which produce the phenomenon in question, contain light as an essential ingredient. The sulphur, or phosphorus combines with the base of the metal, earth, or alkali; while at the same time, the *caloric*, to which the sulphur or phosphorus owed its fluidity, combines with the *light* of the metal, earth, or alkali; and the compound flies off under the form of *fire*.

Thus the process is exactly the same with combustion, excepting as far as regards the product. The melted sulphur, or phosphorus, acts the part of the *supporter*, while the metal, earth, or alkali, occupies the place of the *combustible*. The first furnishes caloric, the second light, while the base of each combines together. Hence we see that the base of sulphurets and phosphurets resembles the base of products in being destitute of light; the formation of these bodies exhibiting the separation of fire like *combustion*, but the product differing from a product of combustion in being destitute of oxygen, Dr. Thompson distinguishes the process by the title of *semi-combustion*; indicating by the term, that it possesses one-half of the characteristic marks of combustion, but is destitute of the other half.

The only part of this theory which requires proof is, that light is a component part of the earths and alkalies. But as potassa and lime are the only bodies of that nature, which we are certain to be capable of exhibiting the phenomena of semi-combustion, the proofs must of necessity be confined to them. That *lime* contains light as a component part, has been long known. Meyer and Pelletier observed long ago, that when water is poured upon lime, not only heat but light is emitted. Light is emitted also abundantly, when sulphuric acid is poured upon magnesia, or upon lime, potassa, or soda, freed from the water of crystallisation. In all these cases, a *semi-combustion* takes place. The water and the acid being solidified, give out *caloric*, while the lime or potassa gives out *light*.

That lime, during its burning, combines with light, and that light is a component part of lime, is demonstrated by the following experiment, for which we are indebted to Scheele.

Fluor spar (fluate of lime) has the property of phosphorescing strongly when heated, but the experiment does not succeed twice with the same specimen. After it has been once heated sufficiently, no subsequent heat will cause it to phosphoresce. Now phosphorescence is merely the emission of light; light of course is a component part of fluor spar, and heat has the property of separating it. But the phosphorescing quality of the spar may be again recovered to it, or, which is the same thing, the light which the spar had lost may be restored by the following process:—

Decompose the fluate of lime by sulphuric acid, and preserve the fluoric acid separate. Boil the sulphate of lime thus formed, with a sufficient quantity of carbonate of soda; a double decomposition takes place; sulphate of soda remains in solution, and carbonate of lime precipitates. Ignite this precipitate in a crucible, till it is reduced to lime, and combine it with the fluoric acid to which it was formerly united. The fluor spar thus regenerated, phosphoresces as at first. Hence the lime, during its ignition, must have combined with light.

That potassa contains light, may be proved in the same manner as the existence of that body in lime. Now as potassa is deprived of its carbonic acid by lime, the Doctor supposes that the process must be a double decomposition; namely, that the base of the lime combines with carbonic acid, while its light combines with the potassa.

These remarks on semi-combustion might easily be much enlarged upon: for it is obvious, that whenever a liquid combines with a solid containing light, and the product is a solid body, something analogous to semi-combustion must take place.

COMEDO. (From *comedo*, a glutton.) The comedones of old writers are a sort of worm which eats into the skin and devours the flesh.

CO'MFREY. See *Symphytum*.

COMI'SDI. The gum-arabic.

COMI'STE. The epilepsy. This name arose from the frequency of persons being seized with this disorder, while in the assemblies called Comitia.

COMITI'SSA. A countess. Some preparations are distinguished by this name; as *Pulvis Comitissæ de Cantia*, the Countess of Kent's powder. Also the Cinchona was called *Pulvis Comitissæ*.

COMMAGE'NUM. (From *Commagene*, a place in Syria, whence it was brought.) Syrian ointment, mentioned by Galen.

COMMANDUCA'TIO. (From *commanduco*, to eat.) The act of mastication, or chewing.

COMMA'NSUM. (From *commando*, to eat.) A masticatory. A medicine put into the mouth and chewed, to promote a discharge of phlegm, or saliva.

COMMENDATO'RIUS. (From *commendo*, to recommend.) An epithet of the traumatic balsam, *tinctura Benzoes composita*, from its singular virtues and usefulness.

CO'MMI. Gum. When alone it signifies gum-arabic. The *κομμι λευκον*, mentioned by Hippocrates in his De Morb. Mulieb., is gum-arabic.

COMMISSU'RA. (From *committo*, to join together.) A suture, juncture, or joint. A term applied in anatomy to the corners of the lips, where they meet together; and also to certain parts of the brain which go across and join one hemisphere to the other.

COMMISSURA ANTERIOR CEREBRI. The white nerve-like substance which crosses the anterior part of the third ventricle of the brain, immediately above the infundibulum, and between the anterior crura of the fornix; uniting one hemisphere of the brain with the other.

COMMISSURA MAGNA CEREBRI. The *corpus* *callosum* of the brain is so termed by some writers.

Commissura posterior cerebri. A white nerve-like substance, which passes from one hemisphere of the brain across to the other, immediately over the opening of the aquæduct of Sylvius, in the posterior part of the third ventricle of the brain, and above the *corpora quadrigemina.*

Commu′nicant. (From *communico*, to make partake.) A term applied by Bellini, to fevers of two kinds afflicting the same person, wherein as one goes off the other immediately succeeds.

Compa′ges. (From *compingo*, to put together.) A suture, or joint. A commissure.

COMPA′RATIVE. That which illustrates by comparing with the human body: applied to anatomy and physiology. See *Anatomy.*

Compeba. See *Piper Cubeba.*

Complete Flower. See *Flos.*

Completion. A term used by the ancient writers in various acceptations; but latterly it signifies only the same as *Plethora.*

COMPLE′XUS. (From *complector*, to comprise.) *Complexus seu biventer cervicis* of Albinus. *Dorso trachelon occipital* of Dumas. A muscle situated on the back part of the neck, that draws the head backwards, and to one side: and when both act, they draw the head directly backward. It arises from the transverse processes of the seven superior vertebræ of the back, and four inferior of the neck, by as many distinct tendinous origins; in its ascent, it receives a fleshy slip from the spinous process of the first vertebra of the back: from these different origins it runs upwards, and is every where intermixed with tendinous fibres. It is inserted, tendinous and fleshy, into the inferior edge of the protuberance in the middle of the os occipitis, and into a part of the curved line that runs forwards from that protuberance. It draws the head backwards.

Complexus minor. See *Trachelo-mastoideus.*

COMPOSITUS. Compound. The result or effect of a composition of different things; or that which arises from them. It stands opposed to simple. In botany, applied to leaves and flowers. See *Flos*, and *Folium.*

COMPOUND. See *Compositus.*

Compound affinity. See *Attraction.*

COMPRE′SSION. (*Compressio;* from *comprimo*, to press together.) A diseased state of the body, or of a part, the effect of something pressing upon it. The term is generally applied to the brain. Compression of the brain should be distinguished from concussion and inflammation. When the brain is compressed either by bone, extravasated blood, or any other fluid, there is a general insensibility, the eyes are half open, the pupils dilated and motionless, even when a candle is brought near the eye; the retina is insensible; the limbs relaxed; the breathing stertorous; the pulse slow, and, according to Abernethy, less subject to intermission than in cases of concussion. Nor is the patient ever sick, when the pressure on the brain, and the general insensibility, are considerable; for the very action of vomiting betrays an irritability in the stomach and œsophagus.

COMPRE′SSOR. (*Compressor;* from *comprimo*, to press together.) A name applied to those muscles which press together the parts on which they act.

Compressor naris. *Rinæus vel nasalis* of Douglas. *Transversalis vel myrtiformis* of Winslow. *Dilatores alarum nasi* of Cowper; and *Maxillo narinal* of Dumas. A muscle of the nose, that compresses the alæ towards the septum nasi particularly when we want to smell acutely. It also corrugates the nose, and assists in expressing certain passions. It arises, by a narrow beginning, from the root of the ala nasi externally, and spreads into a number of thin, separate fibres, which run up along the cartilage in an oblique manner towards the back of the nose, where it joins with its fellow, and is inserted into the narrow extremity of the os nasi, and nasal process of the superior maxillary bone.

COMPRESSUS. Compressed; flattened laterally: applied to leaves. See *Leaf.*

COMPTONITE. A new mineral first brought into this country by Lord Compton, and found in Drusy cavities, in ejected masses, on Mount Vesuvius.

Compu′nctio. (From *compungo*, to prick.) A puncture.

CONA′RIUM. (From κωνος: so named from its conical shape.) A cone. See *Pineal gland.*

Concau′sa. (From *con*, with, and *causa*, a cause.) A cause which co-operates with another in the production of a disease.

CONCAVUS. Hollow; depressed in the middle. Applied to leaves, petals, &c. depressed in their centre, owing, as it were, to a tightness in some part of the circumference; as in *Cyamus nelumbo*, and the petals of the *Galanthus nivalis.*

CONCENTRA′TION. (*Concentratio;* from *con*, and *centrum*, a centre.) The volatilising of part of the water of fluids, in order to improve their strength. The matter to be concentrated, therefore, must be of superior fixity to water. This operation is performed on some acids, particularly the sulphuric and phosphoric. It is also employed in solutions of alkalies and neutral salts.

CONCENTRIO. *Bulbus concentricus.* A concentric bulb, is one of the laminated kind, well illustrated in the common onion, *Allium cepa.*

CONCEPTACULUM. A former name for what is now called in botany receptaculum.

CONCE′PTION. (*Conceptio;* from *concipio*, to conceive.) The impregnation of the ovulum in the female ovarium, by the subtile prolific aura of the semen virile. In order to have a fruitful coition, it is necessary that the semen be propelled into the uterus, or vagina, so that its fecundating vapour shall be conveyed through the Fallopian tube to the ovarium: it is also necessary that there be a certain state of the ovarium of the female in order to impregnate it; which is, that the ovum shall be mature, and embraced by the fimbriæ of the Fallopian tube, to convey that vivifying principle to the ovum. See *Generation.*

CO′NCHA. (*Concha*, κογχη, a liquid measure among the Athenians.) A term applied by anatomists to several parts of the body; as the hollow of the ear, the spongy bones of the nose, &c.

Concha auriculæ. See *Auricula.*

Concha auris. The hollow part of the cartilage of the outer ear.

Concha margaritifera. The shell from which pearls are obtained. See *Margarita.*

Conchæ narium. The turbinated portion of the ethmoid bone, and the inferior spongy bones of the nose, which are covered by the Schneiderian membrane, are so termed.

CO'NCHUS. (From κογχη, a shell; so named from their likeness to a shell.) The cranium, and the cavity of the eye.

CONCI'DENS. (From *concido*, to decay.) 1. A decrease of bulk in the whole or any part of the body.

2. A diminution of a tumour.

CONCOAGULA'TIO. (From *con*, and *coagulo*, to coagulate together.) The coagulation or crystallisation of different salts, first dissolved together in the same fluid.

CONCO'CTIO. (From *concoquo*, to digest.) 1. Concoction; digestion. This term was formerly very generally used to express that operation of nature upon morbid matter which renders it fit to be separated from the healthy fluid.

2. The alteration which the food undergoes in the primæ viæ.

CONCREMA'TIO. (From *con*, and *cremo*, to burn together.) Calcination.

CONCRE'TION. (*Concretio*; from *concresco*, to grow together.)

1. The condensation of any fluid substance into a more solid consistence.

2. The growing together of parts which, in a natural state, are separate.

CONCU'RSUS. (From *concurro*, to meet together.) The congeries or collection of symptoms which constitute and distinguish the particular disease.

CONCU'SSION. (From *concutio*, to shake together.) Concussion of the brain. Various alarming symptoms, followed sometimes by the most fatal consequences, are found to attend great violence offered to the head; and upon the strictest examination, both of the living and the dead, neither fissure, fracture, nor extravasation of any kind can be discovered. The same symptoms and the same events are met with, when the head has received no injury at all *ab externo*, but has only been violently shaken; nay, when only the body, or general frame, has seemed to have sustained the violence. The symptoms attending a concussion, are generally in proportion to the degree of violence which the brain itself has sustained, and which, indeed, is cognizable only by the symptoms. If the concussion be very great, all sense and power of motion are immediately abolished, and death follows soon; but between this degree and that slight confusion (or stunning, as it is called,) which attends most violences done to the head, there are many shades. The following is Abernethy's description of the symptoms of concussion, which he is of opinion, may be divided into three stages.

The first is that state of insensibility and derangement of the bodily powers which immediately succeeds the accident. While it lasts, the patient scarcely feels any injury that may be inflicted on him. His breathing is difficult, but in general without stertor; his pulse intermitting, and his extremities cold. But such a state cannot last long; it goes off gradually, and is succeeded by another, which is considered as the *second* stage of concussion. In this, the pulse and respiration become better, and, though not regularly performed, are sufficient to maintain life, and to diffuse warmth over the extreme parts of the body. The feeling of the patient is now so far restored, that he is sensible of his skin being pinched; but he lies stupid and inattentive to slight external impressions. As the effects of concussion diminish, he becomes capable of replying to questions put to him in a loud tone of voice, especially when they refer to his chief suffering at the time, as pain in the head, &c.; otherwise he answers incoherently, and as if his attention was occupied by something else. As long as the stupor remains, the inflammation of the brain seems to be moderate; but as the former abates, the latter seldom fails to increase; and this constitutes the *third* stage, which is the most important of the series of effects proceeding from a concussion.

These several stages vary considerably in their degree and duration; but more or less of each will be found to take place in every instance where the brain has been violently shaken. Whether they bear any certain proportion to each other or not, is not known; indeed this will depend upon such a variety of circumstances in the constitution, the injury, and the after-treatment, that it must be difficult to determine.

To distinguish between an extravasation and a concussion by the symptoms only, Mr. Pott says, is frequently a very difficult matter; sometimes an impossible one. The similarity of the effects, in some cases, and the very small space of time which may intervene between the going off of the one and accession of the other, render this a very nice exercise of the judgment. The first stunning or deprivation of sense, whether total or partial, may be from either, and no man can tell from which; but when these first symptoms have been removed, or have spontaneously disappeared, if such patient is again oppressed with drowsiness, or stupidity, or total or partial loss of sense, it then becomes probable that the first complaints were from concussion, and that the latter are from extravasation; and the greater the distance of time between the two, the greater is the probability not only that an extravasation is the cause, but that the extravasation is of the limpid kind, made gradatim, and within the brain.

Whoever seriously reflects on the nature of these two causes of evil within the cranium, and considers them as liable to frequent combination in the same subject, and at the same time considers that, in many instances, no degree of information can be obtained from the only person capable of giving it (the patient,) will immediately be sensible how very difficult a part a practitioner has to act in many of these cases, and how very unjust it must be to call that ignorance which is only a just diffidence arising from the obscurity of the subject, and the impossibility of attaining materials to form a clear judgment.

Abernethy observes, that in cases of simple concussion, the insensibility is not so great, as where compression exists, the pupils are more contracted, the muscles less relaxed, little or no stertor attends, but the pulse is very intermitting, and in slight cases there is often considerable sickness.

Very different modes of treating these accidents have been practised, and no doubt the same means should not be pursued indiscriminately. Much must depend on the state of the patient, when he received the injury, the degree of this, the time which has elapsed since, and other circumstances. Abernethy considers, that in the first stage little should be done; that the stimulants often employed may be even injurious; but more especially so in the second stage, increasing the tendency to inflammation; and where this has come on, that the antiphlogistic plan must be actively pursued. However, a moderate abstraction of blood, general or topical, will be commonly proper at first, where the habit will allow it, as congestion may be suspected, and to obviate inflammation, especially where the person was intoxicated at the time of the accident; and the effect of this measure may influence the subsequent treatment. If the pulse rose after it, and the patient became more sensible, we should be led to pursue the evacuating plan, taking perhaps more blood, exhibiting active cathartics, as the bowels will be found very torpid, applying cold lotions to the head, &c. These means, however, will be especially called for, when marks of inflammation appear. Sometimes brisk emetics have been very beneficial, as sulphate of zinc, &c.: they are particularly recommended, where the person was under the influence of anger; or the stomach full, when the accident happened; but they are liable to objection, where there are marks of congestion, or increased action in the vessels of the head. If bleeding should lower the pulse, and render the patient worse, evacuations must not be pursued; it may be better generally to wait the gradual return of sensibility, unless the torpor be alarming, like a state of syncope: in which case, or if it continue very long, stimulants appear justified, as ammonia, or others of transient operation, with a blister to the head, to restore some degree of sensibility. If in the sequel marks of irritation appear, as spasms or convulsions, opium joined with antimony, or in the form of Dover's powder, will probably be useful, the necessary evacuations being premised, and the warm bath. In all cases the head should be kept quiet; as the patient is convalescent, tonics, and the shower-bath may be employed with advantage; and it will be particularly necessary to avoid great bodily exertion, stimulating liquors, &c. Should paralytic symptoms remain, stimulants general or local may be required. Where alarming symptoms follow an injury to the head, extravasation may be suspected: and the operation of trepanning, skilfully performed, will do no harm to the patient, but may materially relieve, even by the loss of blood attending.

CONDENSA′TION. (*Condensatio;* from *condenso*, to make thick.) A thickening of any fluid.

CONDIME′NTUM. (From *condio*, to preserve, or season.) A condiment, preserve, or sweetmeat.

CONDU′CTIO. (From *conduco*, to draw along.) In Cœlius Aurelianus, it is a spasm, or convulsion, drawing the muscles out of their proper positions.

CONDU′CTOR. (From *conduco*, to lead, or guide.) A surgical instrument, the use of which is to direct the knife in certain operations. It is more commonly called a director.

CONDUPLICATUS. Folded. Applied to leaves when the margins are clapped flatly together; as in *Roscæa purpurea*, and the bases of sword-shaped leaves. See *Leaf.*

CO′NDYLE. (*Condylus;* from κονδυ, an ancient cup, shaped like a joint.) A round eminence of a bone in any of the joints.

CONDYLO′MA. (*Condyloma, atis.* n.; from κονδυλος, a tubercle, or knot.) A soft, wart-like excrescence, that appears about the anus and pudendum of both sexes. There are several species of condylomata, which have received names from their appearances; as *ficus*, *crystæ*, *thymus*, from their resemblance to a fig, &c.

CONE. See *Strobilus.*

CONEI′ON. (From κωναν, to turn round.) In Hippocrates it imports hemlock. It is said to be thus named, because it produces a vertigo in those who take it inwardly. See *Conium.*

CONE′SSI CORTEX. See *Nerium antidysentericum.*

CONFE′CTION. (*Confectio, onis.* f.; from *conficio*, to make up.) A confection. In general it means any thing made up with sugar. The term, in the new London Pharmacopœia, includes those articles which were formerly called electuaries and conserves, between which there do not appear to be sufficient grounds to make a distinction.

CONFECTIO AMYGDALARUM. Confection of almonds. Take of sweet almonds, an ounce; Acacia gum powdered, a drachm; refined sugar, half an ounce. The almonds having been previously macerated in water, and their external coat removed, beat the whole together, until they are thoroughly incorporated. It has been objected to the almond mixture, which is an article of very general use, that it requires considerable time for its extemporaneous preparation, and that it spoils and cannot be kept when it is made. This will be obviated by the present form, which does keep for a sufficient length of time, and rubs down into the mixture immediately.

CONFECTIO AROMATICA. This preparation was formerly called *Confectio cardiaca. Confectio Raleighana.* Take of cinnamon bark, nutmegs, of each two ounces; cloves, an ounce; cardamom seeds, half an ounce; saffron dried, two ounces; prepared shells, sixteen ounces; refined sugar powdered, two pounds; water, a pint. Reduce the dry substances, mixed together, to very fine powder; then add the water gradually, and mix the whole, until it is incorporated. This preparation is now much simplified by the London college. It is an excellent medicine, possessing stimulant, antispasmodic, and adstringent virtues; and is exhibited with these views to children and adults, in a vast variety of diseases, mixed with other medicines. It may be given in doses of 10 gr. to a drachm.

CONFECTIO AURANTIORUM. *Conserva corticis exterioris aurantii hispalensis. Conserva flavedinis corticum aurantiorum.* Take of fresh external rind of oranges, separated by rasping, a pound; refined sugar, three pounds. Bruise the rind with a wooden pestle, in a stone mortar; then, after adding the sugar, bruise it again, until the whole is thoroughly incorporated. This is well calculated to form the basis of a tonic and stomachic confection, and may be given alone in doses of from two to five drachms, twice or three times a-day.

CONFECTIO CARDIACA. See *Confectio aromatica.*

CONFECTIO CASSIÆ. *Electuarium cassiæ. Electuarium e cassia.* Confection of cassia. Take of fresh cassia pulp, half a pound; manna, two ounces; tamarind pulp, an ounce; syrup of roses, half a pint. Bruise the manna; melt it in the syrup by a water-bath; then mix in the pulps, and evaporate down to a proper consistence. This is a very elegant, pleasant, and mild aperient for the feeble, and for children. Dose from two drachms to an ounce.

CONFECTIO OPII. *Confectio opiata. Philonium Londinense. Philonium Romanum.* Confection of opium. Take of hard opium powdered, six drachms; long pepper, an ounce; ginger root, two ounces; caraway-seeds, three ounces; syrup, a pint. Rub together the opium and the syrup previously heated; then add the remaining articles reduced to powder, and mix. To the credit of modern pharmacy, this is the only one that remains of all those complicated and confused preparations called mithridate, theriaca, &c.; it more nearly approximates, in its composition, the philonium than any other, and may be considered as an effectual substitute for them in practice. This very warm and stimulating confection is admirably calculated to relieve diarrhœa, or spasms of the stomach and bowels, and is frequently ordered in doses of from 10 grs., to half a drachm. About 36 grains contain one of opium.

CONFECTIO PIPERIS NIGRI. Confection of black pepper. Take of black pepper; elecampane, of each a pound; fennel seeds, three pounds; honey; refined sugar, of each two pounds. Rub the dry ingredients together, so as to reduce them to a very fine powder; then, having added the honey, rub them again so that the whole may incorporate. This confection is given internally against a relaxed condition of the extremity of the rectum, producing partial prolapse, and against that piley state which results from weakness. A similar compound has been long celebrated and sold under the name of Ward's paste.

CONFECTIO ROSÆ CANINÆ. *Conserva cynosbati. Conserva fructus cynosbati.* Conserve of hips. Confection of dog-rose. Take of dog-rose pulp, a pound; refined sugar powdered, twenty ounces. Expose the pulp in a water-bath to a gentle heat; then add the sugar gradually, and rub them together until they are thoroughly incorporated. This preparation is cooling and adstringent; it is seldom given alone, but mostly joined to some other medicine, in the form of linctus, or electuary.

CONFECTIO ROSÆ GALLICÆ. *Conserva rosæ. Conserva rosarum rubrarum.* Conserve of red rose. Take of the petals of the red rose, before it is expanded, and without the claws, a pound; refined sugar, three pounds. Bruise the petals in a stone mortar; then, having added the sugar, beat them again together, until they are thoroughly incorporated. This is an excellent sub-astringent composition. Rubbed down with water, it forms an excellent drink, with some lemon juice, in hæmorrhagic complaints; it may also be given with vitriolated zinc, in the form of an electuary.

CONFECTIO RUTÆ. *Electuarium e baccis lauri.* Confection of rue. Take of rue leaves dried, caraway seeds, bay berries, of each an ounce and a half; sagapenum, half an ounce; black pepper, two drachms; clarified honey, sixteen ounces. Rub the dry articles together, into a very fine powder; then add the honey, and mix the whole. Its use is confined to clysters.

CONFECTIO SCAMMONEÆ. *Electuarium scammonii. Electuarium e scammonio. Electuarium caryocostinum.* Confection of scammony. Take of scammony gum resin powdered, an ounce and a half; cloves bruised, ginger root powdered, of each, six drachms; oil of caraway, half a drachm; syrup of roses, as much as is sufficient. Rub the dry articles together, into very fine powder; next rub them again whilst the syrup is gradually added; then add the oil of caraway, and mix the whole well together. This is a strong stimulating cathartic, and calculated to remove worms from the primæ viæ, with which view it is mostly exhibited. Dose from ʒss. to ʒj.

CONFECTIO SENNÆ. *Electuarium sennæ. Electuarium lenitivum.* Confection of senna. Take of senna leaves, eight ounces; figs, a pound; tamarind pulp, pulp of prunes, cassia pulp, of each half a pound; coriander seeds, four ounces; liquorice-root, three ounces; refined sugar, two pounds and a half. Powder the senna leaves with the coriander seeds, and separate, by sifting ten ounces of the mixed powder. Boil the remainder with the figs and the liquorice-root, in four pints of water, until it be reduced to half; then press out and strain the liquor. Evaporate the liquor, until a pint and a half only remains of the whole; then add the sugar, to make syrup. Lastly, mix the pulps gradually with the syrup, and, having added the sifted powder, mix the whole together. This is a mild and elegant aperient, well adapted for pregnant women, and those whose bowels are easily moved. Dose, ʒss. to ℥ss.

CONFERTUS. Clustered, or crowded together: applied to leaves. See *Leaf.*

CONFE'RVA. (From *conferveo*, to knit together.) 1. The name of a genus of plants in the Linnæan system. Class, *Cryptogamia;* Order, *Algæ.*

2. A kind of moss: named from its use formerly in healing broken bones.

CONFERVA HELMINTHOCORTOS. See *Corallina corsicana.*

CONFERVA RIVALIS. This plant, *Conferva; filamentis simplicissimus æqualibus longissimus,* of Linnæus, has been recommended in cases of spasmodic asthma, phthisis, &c. on account of the great quantity of vital air it contains.

CONFIRMA'NTIA. (From *con*, and *firmo*, to strengthen.) 1. Restoratives.

2. Medicines which fasten the teeth in their sockets.

CONFLUENT. Running together. Applied to eruptions. See *Variola.*

CONFLU'XION. Much used by Hippocrates, and his interpreter Galen, from a notion that parts at a distance have mutual consent with one another, and that they are all perspirable by many subtle streams. Paracelsus, according to his way, expressed the former by confederation.

CONFORMA'TIO. (From *conformo*, to shape or fashion.) Conformation. The natural shape and form of any part.

CONFORTA'NTIA. (From *conforto*, to strengthen.) Cordial and strengthening medicines.

CONFORTATI'VA. The same.

CONFU'SIO. (From *confundo*, to mix together.) A confusion, or disorder in the eyes, proceeding from a rupture of the membranes, which include the humours, by which means they are all confounded together.

CONGELA'TI. (From *congelo*, to freeze.) *Congelatici.* Persons afflicted with a catalepsy are so called, by which all sensation seems to be taken away.

CONGELA'TION. (*Congelatio; from congelo*, to freeze.) That change of liquid bodies which takes place when they pass to a solid state, by losing the caloric which kept them in a state of fluidity.

CONGELATI'VA. (From *congelo*, to congeal.) Medicines that inspissate humours, and stop fluxions and rheums.

CO'NGENER. (From *con*, and *genus*, kind.) Of the same kind; concurring in the same action. It is usually said of the muscles.

CONGE'STION. (From *congero*, to amass.) A collection of blood or other fluid; thus we say a congestion of blood in the vessels when they are over distended, and the motion is slow.

CONGLOBA'TE. (*Conglobatus;* from *conglobo*, to gather into a ball.) 1. A term applied to a gland, *Glandula conglobata*, which is formed of a contortion of lymphatic vessels, connected together by cellular structure, having neither a cavity nor any excretory duct: such are the mesenteric, inguinal, axillary glands, &c. See *Gland.*

2. A conglobate *flower*, is a compound one growing in the form of a sphere or globe.

CONGLOMERATE. (*Conglomeratus;* from *conglomero*, to heap upon one.) 1. Applied to a gland, *Glandula conglomerata*, which consists of a number of smaller glomerate glands, the excretory ducts of which all unite into one common duct: such are the salival, parotid glands, &c.

2. Conglomerate *flowers*, are such as are heaped together on a footstalk, to which they are irregularly, but closely connected. See *Panicula*.

CONGLOMERITE. A compound mineral mass, in which angular fragments of rocks are imbedded. The Italian term *breccia*, has the same meaning. In pudding stone, the imbedded fragments are round, bearing the marks of having been polished by attrition.

CONGLUTINA'NTIA. (From *conglutino*, to glue together.) Healing medicines; and such as unite parts disjoined by accident.

CONICUS. Conical. Applied to leaves, nectaries, receptacles, &c.—Nectarium conicum, in the *Utricularia foliosa*, and the receptacle of the daisy, *Anthemis arvensis*, *cotula*, and *Matricaria chamomilla*.

CONIFERÆ. Cone-bearing plants. The name of an order in Linnæus's Fragments of a Natural Method.

CO'NIS. Κονις. Dust; fine powder; ashes; a nit in the hair; scurf from the head; and sometimes it signifies lime.

CONITE. 1. An ash or greenish grey coloured mineral, which becomes brown on exposure to air. It is found in Saxony and Iceland.

2. Dr. Maccullock has given this name to a pulverulent mineral, as fusible as glass into a transparent bead, which he found in the trap hills of Kilpatrick, and the isle of Sky.

CONI'UM. (From *κόνια*, dust, according to Linnæus; or from *κωναω*, *circumago*, on account of its inebriating and poisonous quality.) Hemlock.

1. The name of a genus of plants in the Linnæan system. Class, *Pentandria*; Order, *Digynia*.

2. The pharmacopœial name of the officinal hemlock. See *Conium maculatum*.

Conium maculatum. The systematic name for the *cicuta* of the pharmacopœias. It is called by some *camaran*; by others *abiotos*; and, according to Erotian, *cambeion* is an old Sicilian word for cicuta. *Cicuta major fœtida*. *Conium—seminibus striatis*, of Linnæus.

Hemlock is found in every part of England, and is distinguished from those plants which bear some resemblance to it by the spotted stem. It is generally believed to be a very active poison. In a very moderate dose it is apt to occasion sickness and vertigo; in a larger quantity it produces anxiety, cardialgia, vomiting, convulsions, coma, and death. Baron Stoerk was the first who brought hemlock into repute as a medicine of extraordinary efficacy: and although we have not in this country any direct facts, like those mentioned by Stoerk, proving that inveterate scirrhuses, cancers, ulcers, and many other diseases hitherto deemed irremediable, are to be completely cured by the cicuta; we have however the testimonies of several eminent physicians, showing that some complaints which had resisted other powerful remedies, yielded to hemlock; and that even some disorders, which if not really cancerous, were at least suspected to be of that tendency, were greatly benefited by this remedy. In chronic rheumatisms, some glandular swellings, and in various fixed and periodical pains, the cicuta is now very generally employed; and from daily experience, it appears in such cases to be a very efficacious remedy. It has also been of singular use in the hooping-cough. Nor is it less efficacious when applied externally; a poultice made of oatmeal and the expressed juice, (or a decoction of the extract, when the other cannot be obtained,) allays the most excruciating torturing pains of a cancer, and thus gives rest to the distracted patient.

The proper method of administering conium internally, is to begin with a few grains of the powder or inspissated juice, and gradually to increase the dose until a giddiness affects the head, a motion is felt in the eyes as if pressed outwards, with a slight sickness and trembling agitation of the body. One or more of these symptoms are the evidence of a full dose, which should be continued until they have ceased, and then after a few days the dose may be increased, for little advantage can be expected but by a continuance of the greatest quantity the patient can bear. In some constitutions even small doses greatly offend, occasioning spasms, heat and thirst; in such instances it will be of no service. As the powder of the dried leaves has been thought to act, and may be depended upon with more certainty than the extract, the following direction should be observed in the preparation:—Gather the plant about the end of June, when it is in flower; pick off the little leaves, and throw away the leaf-stalks; dry the small selected leaves in a hot sun, or in a tin or pewter dish before the fire. Preserve them in bags made of strong brown paper, or powder them and keep the powder in glass phials where the light is excluded; for light dissipates the beautiful green colour very soon, and thus the medicine loses its appearance if not its efficacy: this mode is recommended by Dr. Withering. The extract should also be made of the plant gathered at this period. From 2 to 20 grains of the powder may be taken twice or thrice a day.

CONJUGATUS. Conjugate or yoked: applied to leaves, which are said to be conjugate or binate. They consist of one pair of leaflets; as in the *Mimosa*.

CONJUNCTIVA. *Membrana conjunctiva*. The conjunctive membrane of the eye; a thin, transparent, delicate membrane, that lines the internal superficies of one eyelid, and is reflected from thence over the anterior part of the bulb, then reflected again to the edge of the other eyelid. That portion which covers the transparent cornea cannot, without much difficulty, be separated from it. Inflammation of this membrane is called *ophthalmia*.

CONJUNCTUS. Conjoined. A botanical term applied to a tuber which is said to be conjoined when in immediate contact with another, as in many of the *Orchides*.

CONNA'TUS. (From *con*, and *nascor*, to grow together.) 1. Born with a person; the same with *congenitus*.

2. In botany it is applied to leaves, which are said to be connate when united at their base; as in *Chlora perfoliata*.

CONNEXION. See *Articulation*.

CONNIVENS. (From *conniveo*, to make as if he did not see.) In botany applied to petals of flowers, as in those of the *Rumex*, and to the receptacle of the fig, which the fruit really is, being a fleshy connivent receptacle, enclosing and hiding the florets.

Connutri'tus. (From *con* and *nutrior*, to be nourished with.) It is what becomes habitual to a person from his particular nourishment, or what breaks out into a disease in process of time, which gradually had its foundation in the first aliments, as from sucking a distempered nurse, or the like.

Conquassa'tio. Conquassation. In pharmacy it is a species of comminution, or an operation by which moist concrete substances, as recent vegetables, fruits, the softer parts of animals, &c.

are agitated and bruised, till, partly by their proper succulence, or by the affusion of some liquor, they are reduced to a soft pulp.

CONRI'NGIUS, HERMAN, was born at Norden, in East Friesland, 1606, and graduated in medicine at Helmstat, where he soon after became professor in that science, and subsequently in physics, law, and politics. He was also made physician and aulic counsellor to the Queen of Sweden, the king of Denmark, and several of the German princes. He wrote numerous works in philosophy, medicine, and history, displaying great learning, and long highly esteemed. In one treatise he refers the degeneracy of the modern Germans to their altered mode of living, the use of stoves, tobacco, &c. He published also an “Introduction to the whole Art of Medicine, and its several Parts,” containing a History and Bibliotheca Medica, with numerous Dissertations on particular Diseases. He died in 1681.

CONSENT. Consent of parts. See *Sympathy*.

CONSE'RVA. (From *conservo*, to keep.) A conserve. A composition of some recent vegetable and sugar, beat together into an uniform mass of the consistence of honey; as conserve of hips, orange peel, &c. Conserves are called confections in the last edition of the London Pharmacopœia. See *Confectio*.

CONSERVA ABSINTHII MARITIMI. See *Artemisia maritima*.

CONSERVA ARI. This is occasionally exhibited as a stimulant and diuretic. See *Arum maculatum*.

CONSERVA AURANTII HISPALENSIS. See *Confectio aurantiorum*.

CONSERVA CYNOSBATI. See *Confectio rosæ caninæ*.

CONSERVA LUJULÆ. A preparation of wood-sorrel, possessing acid, cooling, and antiseptic qualities. See *Oxalis acetosella*.

CONSERVA MENTHÆ. This preparation of mint is given occasionally as a stomachic, in sickness and weakness of the stomach. See *Mentha viridis*.

CONSERVA PRUNI SYLVESTRIS. Astringent virtues are ascribed to this medicine, which is now seldom used but in private formulæ.

CONSERVA ROSÆ. This conserve, rubbed down with water, to which is added some lemon juice, forms an excellent drink in hæmorrhagic complaints. See *Confectio rosæ gallicæ*.

CONSERVA SCILLÆ. A preparation of Squills, which affords an excellent basis for an electuary, possessing expectorant and diuretic qualities.

CONSISTE'NTIA. (From *consisto*, to abide.) The state or acme of a disease. The appearance or state of the humours and excrements.

CONSO'LIDA. (So called, *quia consolidandi et conglutinandi vi pollet*; from its power in agglutinating and joining together things broken.) See *Symphytum*.

CONSOLIDA AUREA. See *Solidago virga aurea*.

CONSOLIDA MAJOR. See *Symphytum*.

CONSOLIDA MEDIA. See *Ajuga pyramidalis*.

CONSOLIDA MINOR. See *Prunella*.

CONSOLIDA REGALIS. See *Delphinium consolida*.

CONSOLIDA SARACENICA. See *Solidago virga aurea*.

CONSOUND. See *Symphytum*.

Consound middle. See *Ajuga pyramidalis*.

CONSTANTI'NUS, AFRICANUS, was born at Carthage, towards the middle of the 11th century. He lived near forty years at Babylon, and was celebrated for his knowledge of the Eastern languages. Among the sciences, medicine appears to have principally occupied his attention; and two of his works were thought deserving of being printed at Bâle, about 4½ centuries after his death, which occurred in 1087. They are thought however to have been chiefly translated from Arabian writers.

CONSTIPATION. (*Constipatio*; from *constipo*, to crowd together.) *Obstipatio*. Costiveness. A person is said to be costive when the alvine excrements are not expelled daily, and when the fæces are so hardened as not to receive their form from the impression of the rectum upon them.

CONSTITUTION. *Constitutio*. The general condition of the body, as evinced by the peculiarities in the performance of its functions: such are, the peculiar predisposition to certain diseases, or liability of particular organs to disease; the varieties in digestion, in muscular power and motion, in sleep, in the appetite, &c. Some marked peculiarities of constitution are observed to be accompanied with certain external characters, such as a particular colour and texture of the skin, and of the hair, and also with a peculiarity of form and disposition of mind; all of which have been observed from the earliest time, and divided into classes: and which received names during the prevalence of the humeral pathology which they still retain. See *Temperament*.

CONSTRICTI'VA. (From *constringo*, to bind together.) Styptics.

CONSTRI'CTOR. (From *constringo*, to bind together.) A name given to those muscles which contract any opening of the body.

CONSTRICTOR ALÆ NASI. See *Depressor labii superioris alæque nasi*.

CONSTICTOR ANI. See *Sphincter ani*.

CONSTRICTOR ISTHMI FAUCIUM. *Glossostaphilinus* of Winslow, Douglas, and Cowper; and *Glosso staphilin* of Dumas. A muscle situated at the side of the entry of the fauces, that draws the *velum pendulum palati* towards the root of the tongue, which it raises at the same time, and with its fellow contracts the passage between the two arches, by which it shuts the opening of the fauces.

CONSTRICTOR LABIORUM. See *Orbicularis oris*.

CONSTRICTOR ORIS. See *Orbicularis oris*.

CONSTRICTOR PALPEBRARUM. See *Orbicularis palpebrarum*.

CONSTRICTORES PHARYNGÆI. The muscles of the œsophagus.

CONSTRICTOR PHARYNGIS INFERIOR. *Crico pharyngeus*; *Thyro-pharyngeus* of Douglas and Winslow. *Cricothyropharyngien* of Dumas. A muscle situated on the posterior part of the pharynx. It arises from the side of the thyroid cartilage, near the attachment of the sternohyoideus and thyrohyoideus muscles; and from the cricoid cartilage, near the crico-thyroideus; it is inserted into the white line, where it joins with its fellow, the superior fibres running obliquely upwards, covering nearly one-half of the middle constrictor, and terminating in a point: the inferior fibres run more transversely, and cover the beginning of the œsophagus. Its use is to compress that part of the pharynx which it covers, and to raise it with the larynx a little upwards.

CONSTRICTOR PHARYNGIS MEDIUS. *Hyopharyngeus* and *cephalo-pharyngeus* of Douglas and Winslow. *Chondro-pharyngeus* of Douglas. *Syndesmo-pharyngeus* of Winslow. *Cephalopharyngeus* of Winslow and Douglas. *Hyoglosso basi pharyngien* of Dumas. A muscle situated on the posterior part of the pharynx. It arises from the appendix of the os hyoides, from the cornu of that bone, and from the ligament which connects it to the thyroid cartilage; the fibres of the superior part running obliquely upwards, and covering a considerable part of the superior constrictor, terminate in a point; and it is inserted into the middle of the cuneiform process of the os occipitis, before the foramen magnum, and joined to its fellow at a white line in the middle part of the pharynx. This muscle compresses that part of the pharynx which it covers, and draws it and the os hyoides upwards.

CONSTRICTOR PHARYNGIS SUPERIOR. *Glosso-pharyngeus; Mylo-pharyngeus; Pterygo-pharyngeus* of Douglas and Winslow, and *Pterigo syndesmo staphili pharyngien* of Dumas. A muscle situated on the posterior part of the pharynx. It arises above, from the cuneiform process of the os occipitis, before the foramen magnum, from the pterygoid process of the sphenoid bone, from the upper and under jaw, near the roots of the last dentes molares, and between the jaws. It is inserted in the middle of the pharynx. Its use is to compress the upper part of the pharynx, and to draw it forwards and upwards.

CONSTRICTOR VESICÆ URINARIÆ. See *Detrusor urinæ.*

CONSTRICTO'RIUS. A disease attended with constriction, or spasm.

CONSTRINGEN'TIA. (From *constringo*, to bind together.) Astringent medicines. See *Astringent.*

CONSUMPTION. (From *consumo*, to waste away.) See *Phthisis.*

CONTABESCE'NTIA. (From *contabesco*, to pine or waste away.) An atrophy, or nervous consumption.

CONTAGION. (*Contagio*; from *contango*, to meet or touch each other.) This word properly imports the application of any poisonous matter to the body through the medium of touch. It is applied to those very subtile particles arising from putrid substances, or from persons labouring under certain diseases, which communicate the diseases to others; as the contagion of putrid fever, the effluvia of dead animal or vegetable substances, the miasm of bogs and fens, the virus of small-pox, lues venerea, &c. &c.

The principal diseases excited by poisonous miasmata are, intermittent, remittent, and yellow fevers, dysentery and typhus. That of the last is generated in the human body itself, and is sometimes called the typhoid fomes. The other miasmata are produced from moist vegetable matter, in some unknown state of decomposition. The contagious *virus* of the plague, small-pox, measles, chincough, cynanche maligna, and scarlet fever, as well as of typhus and the jail fever, operates to a much more limited distance through the intermedium of the atmosphere, than the marsh miasmata. Contact of a diseased person is said to be necessary for the communication of plague; and approach within 2 or 3 yards of him, for that of typhus. The Walcheren miasmata extended their pestilential influence to vessels riding at anchor, fully a quarter of a mile from the shore.

The chemical nature of all these poisonous effluvia is little understood. They undoubtedly consist, however, of hydrogen, united with sulphur, phosphorus, carbon, and azot, in unknown proportions, and unknown states of combination. The proper neutralizers or destroyers of these gasiform poisons, are nitric acid vapour, muriatic acid gas, and chlorine. The last two are the most efficacious; but require to be used in situations from which the patients can be removed at the time of the application. Nitric acid vapour may, however, be diffused in the apartments of the sick, without much inconvenience. Bed-clothes, particularly blankets, can retain the contagious fomes, in an active state, for almost any length of time. Hence, they ought to be fumigated with peculiar care. The vapour of burning sulphur or sulphurous acid is used in the East, against the plague. It is much inferior in power to the other antiloimic reagents.

There does not appear to be any distinction commonly made between contagious and infectious diseases.

CONTE'NSIO. (From *contineo*, to restrain.) It is sometimes used to express a tension or stricture.

CO'NTINENS FEBRIS. A continent fever, which proceeds regularly in the same tenor, without either exacerbation or remission. This rarely, if ever, happens.

CONTI'NUA FEBRIS. (From *continuo*, to persevere.) A continued fever. See *Febris continua.*

CONTINUED. (*Continuus*; from *continuo*, to persevere.) A term applied in pathology to diseases which go on with a regular tenor of symptoms, but mostly to fevers, the symptoms of which continue, without intermission, until the disease terminates: hence continual fevers in distinction to intermittent fevers.

CONTINUUS. See *Continued.*

CONTO'RSIO. (From *contorqueo*, to twist about.) A contortion, or twisting. In medicine this word has various significations, and is applied to the iliac passion, to luxation of the vertebræ, head, &c.

CONTORTÆ. Twisted plants. The name of an order in Linnæus's Fragments of a Natural Method, consisting of plants which have a single petal that is twisted or bent towards the side, as *Nerium, Vinca*, &c.

CONTORTUS. (From *con*, and *torqueo*, to twist.) Twisted. Applied to the seed-vessel of plants; as the *legumen contortum* of the *Medicago sativa.*

CONTRA-APERTURA. (From *contra*, against, and *aperio*, to open.) A counter-opening. An opening made opposite to the one that already exists.

CONTRACTILITY. *Contractilitas.* A property in bodies, the effect of the cohesive power, by which their particles resume their former propinquity when the force ceases which was applied to separate them. It also denotes the power, which muscular fibres possess of shortening themselves.

CONTRACTION. (From *contraho*, to draw together.) *Contractura; Beriberia.* A rigid contraction of the joints. It is a genus of disease in the class *Locales*, and order *Dyscinesiæ* of Cullen. The species are,

1. *Contractura primaria*, from a rigid contraction of the muscles, called also obstipitas; a word that, with any other annexed, distinguishes the variety of the contraction. Of this species he forms four varieties. 1. *Contractura ab inflammatione*, when it arises from inflammation. 2. *Contractura à spasmo*, called also tonic spasm and cramp, when it depends upon spasm. 3. *Contractura ob antagonistas paraliticos*, from the antagonist muscles losing their action. 4. *Contractura ab acrimoniâ irritante*, which is induced by some irritating cause.

2. *Contractura articularis*, originating from a disease of the joint.

CONTRAFISSU'RA. (From *contra*, against, and *findo*, to cleave.) *Contre-coup* of French writers. A fracture in a part opposite to that in which the blow is received; as when the frontal bone is broken by a fall on the occiput, where the bone remains sound.

CONTRAHE'NTIA. (From *contraho*, to contract.) Medicines which shorten and strengthen the fibres. Astringents are the only medicines of this nature.

CONTRA-INDICATION. (*Contra-indicatio*; from *contra*, against, and *indico*, to show.) A symptom attending a disease, which forbids the exhibition of a remedy which would otherwise be employed; for instance, bark and acids are usually given in putrid fevers; but if there be difficulty of breathing, or inflammation of any viscus, they are contra-indications to their use.

CONTRA-LUNA'RIS. (From *contra*, and *luna*, the moon.) An epithet given by Dietericus to a woman who conceives during the menstrual discharge.

CONTRA-SEMEN. See *Artemisia Santonica*.

CONTRAYE'RVA. (From *contra*, against, and *yerva*, poison, Span.; *i. e.* an herb good against poison.) See *Dorstenia*.

CONTRAYERVA ALBA. *Contrayerva Germanorum*. A name for a species of asclepias.

CONTRAYERVA NOVA. Mexican contrayerva. See *Psoralea pentaphylla*.

CONTRAYERVA VIRGINIANA. See *Aristolochia serpentaria*.

Contre-coup. See *Contrafissura*.

CONTRI'TIO. The act of grinding, or reducing to powder.

CONTUSION. (*Contusio*; from *contundo*, to knock together.) A bruise, or contused wound.

CONUS. A cone. See *Strobilus*.

CONVALESCENCE. (*Convalescentia*; from *convalesco*, to grow well.) The recovery of health after the cure of a disease. The period of convalescence is that space from the departure of a disease, to the recovery of the strength lost by it.

CONVALESCENT. Recovering or returning to a state of health after the cure of a disease.

CONVALLA'RIA. (From *convallis*, a valley; named from its abounding in valleys and marshes.) The name of a genus of plants in the Linnæan system. Class, *Hexandria*; Order, *Monogynia*.

CONVALLARIA MAJALIS. The systematic name of the lily of the valley. *Lilium convallium*; *Convallaria*; *Maianthemum*. May-lily. The flowers of this plant. *Convallaria—scapo nudo* of Linnæus, have a penetrating bitter taste, and are given in nervous and catarrhal disorders. When dried and powdered, they prove strongly purgative. Watery or spirituous extracts made from them, given in doses of a scruple, or drachm, act as gentle stimulating aperients and laxatives; and seem to partake of the purgative virtue, as well as the bitterness of aloes. The roots, in the form of tincture, or infusion, act as a sternutatory when snuffed up the nose, and as a laxative or purgative when taken internally.

CONVALLARIA POLYGONATUM. The systematic name of Solomon's seal. *Sigillum Salomonis*; *Convallaria—foliis alternis amplexicaulibus, caule ancipiti, pedunculis, axilaribus subunifloris*, of Linnæus. The roots are applied externally as adstringents, and are administered internally as corroborants.

CONVEXUS. Convex. A term in very general use in anatomy, botany, &c.

CONVOLU'TA OSSA. See *Spongiosa ossa*.

CONVOLU'TUS. Rolled up or folded. Applied to bones, membranes, leaves, &c.

CONVO'LVULUS. (From *convolvo*, to roll together, or entwine.)

1. A name for the iliac passion.

2. The name of a genus of plants in the Linnæan system, so called from their twisting round others (Class, *Pentandria*; Order, *Monogynia*,) which affords the Jalapa, mechoacana, turbith, and scammony. The whole genus consists of plants containing a milky juice strongly cathartic and caustic.

CONVOLVULUS AMERICANUS. The jalap root. See *Convolvulus jalapa*.

CONVOLVULUS BATATAS. *Batatas*. A native of the West Indies. Its root is firm and of a pale brown on the outside, and white within. When boiled it is sweet, like chesnuts, and is esteemed by some as an esculent.

CONVOLVULUS CANTABRICA. A name for the cantabrica. *Convolvulus minimus spicæ foliis*; *Convolvulus linariæ folio*; *Convolvulus Cantabrica* of Linnæus. Lavender-leaved bind-weed. Pliny says it was discovered in the time of Augustus, in the country of the Cantabri in Spain; whence its name. It is anthelmintic and actively cathartic.

CONVOLVULUS COLUBRINUS. The pariera brava. See *Cissampelos pareira*.

CONVOLVULUS JALAPA. The systematic name of the jalap plant. *Jalapium mechoacanna nigra*. *Convulvulus; caule volubli; foliis ovatis, subcordatis, obtusis, obsolete repandis, subtus villosis; pedunculis unifloris* of Linnæus. It is a native of South America. In the shops, the root is found both cut into slices and whole, of an oval shape, solid, ponderous, blackish on the outside, but grey within, and marked with several dark veins, by the number of which, and by its hardness, heaviness, and dark colour, the goodness of the root is to be estimated. It has scarcely any smell, and very little taste, but to the tongue, and to the throat, manifests a slight degree of pungency. The medicinal activity of jalap resides principally, if not wholly, in the resin, which, though given in small doses, occasions violent tormina. The root powdered is a very common, efficacious, and safe purgative, as daily experience evinces; but, according as it contains more or less resin, its effects must of course vary. In large doses, or when joined with calomel, it is recommended as an anthelmintic and hydragogue. In the pharmacopœias, this root is ordered in the form of tincture and extract; and the Edinburgh College directs it also in powder, with twice its weight of crystals of tartar.

CONVOLVULUS MAJOR ALBUS. See *Convolvulus sepium*.

CONVOLVULUS MARITIMUS. The brassica maritima, or sea colewort.

CONVOLVULUS MECHOACAN. *Mechoacanna*; *Jalapa alba*; or *Bryonia alba Peruviana*; *Rhabarbarum album*. Mechoacan. The root of this species of convolvulus is brought from Mexico. It possesses aperient properties, and was long used as the common purge of this country, but is now wholly superseded by jalap.

CONVOLVULUS SCAMMONIA. The systematic name of the scammony plant. See *Scammonium*; *Convolvulus syriacus*; *Scammonium syriacum*; *Diagrydium*. This plant, *Convolvulus—foliis sagittatis postice truncatis, pedunculis teretibus subtifloris* of Linnæus, affords the concrete gummi-resinous juice termed scammony. It grows plentifully about Maraash, Antioch, Eallib, and towards Tripoli, in Syria. No part of the dried plant possesses any medicinal quality, but the root, which Dr. Russel administered in decoction, and found it to be a pleasant and mild cathartic. It is from the milky juice of the root that we obtain the officinal scammony, which is procured in the following manner by the peasants, who collect it in the begining of June. Having cleared away the earth from about the root, they cut off the top in an oblique direction, about two inches below where the stalks spring from it. Under the most depending part of the slope, they fix a shell, or some other convenient receptacle, into which the milky juice gradually flows. It is left there about twelve hours, which time is sufficient for draining off the whole juice; this, however, is in small quantity, each root affording but a very few drachms. This juice from the several roots is put together, often into the leg of an old boot, for want of some more proper vessel, where in a little time, it grows hard, and is the genuine scammony. The smell of scammony is rather unpleasant, and the taste bitterish and slightly acrid. The different proportions of gum and resin, of which it consists, have been variously stated; but, as proof spirit is the best menstruum for it, these substances are supposed to be nearly in equal parts. It is brought from Aleppo and Smyrna in masses, generally of a light shining grey colour, and friable texture; of rather an unpleasant smell and bitterish and slightly acrid taste. The scammony of Aleppo is by far the purest. That of Smyrna is ponderous, black, and mixed with extraneous matters. Scammony appears to have been well known to the Greek and Arabian physicians, and was exhibited internally as a purgative, and externally for the itch, tinea, fixed pains, &c. It is seldom given alone, but enters several compounds, which are administered as purgatives.

Convolvulus sepium. *Convolvulus major albus.* The juice of this plant, *Convolvulus—foliis sagittatis postice truncatis pedunculis tetragonis, unifloris*, of Linnæus, is violently purgative, and given in dropsical affections. A poultice of the herb, made with oil, is recommended in white swellings of the knee joint.

Convolvulus soldanella. The systematic name of the sea convolvulus. Κραμβη ϑαλασσια. *Brassica marina; Convolvulus maritimus; Soldanella.* Soldanella. This plant, *Convolvulus—foliis reniformibus, pedunculis unifloris*, of Linnæus, is a native of our coasts. The leaves are said to be a drastic purge. It is only used by the common people, the pharmacopœias having now substituted more safe and valuable remedies in its place.

Convolvulus syriacus. The scammony plant. See *Convolvulus scammonia.*

Convolvulus turpethum. The systematic name of the turbith plant. *Turpethum.* The cortical part of the root of a species of convolvulus, brought from the East Indies, in oblong pieces: it is of a brown or ash colour on the outside, and whitish within. The best is ponderous, not wrinkled, easy to break, and discovers to the eye a large quantity of resinous matter. When chewed, it at first imparts a sweetish taste, which is followed by a nauseous acrimony. It is considered as a purgative, liable to much irregularity of action.

CONVULSION. (*Convulsio;* from *convello*, to pull together.) *Hieranosos; Distentio nervorum; Syspacia convulsio* of Good. Clonic spasm. A diseased action of muscular fibres, known by alternate relaxations, with violent and involuntary contractions of the muscular parts, without sleep. Cullen arranges convulsion in the class *Neuroses*, and order *Spasmi*. Convulsions are universal or partial, and have obtained different names, according to the parts affected, or the symptoms; as the *risus sardonicus*, when the muscles of the face are affected; St. Vitus's dance, when the muscles of the arm are thrown into involuntary motions, with lameness and rotations. The hysterical epilepsy, or other epilepsies, arising from different causes, are convulsive diseases of the universal kind: the muscles of the globe of the eye, throwing the eye into involuntary distortions in defiance of the direction of the will, are instances of partial convulsion. The muscles principally affected in all species of convulsions, are those immediately under the direction of the will; as those of the eyelids, eye, face, jaws, neck, superior and inferior extremities. The muscles of respiration acting both voluntarily and involuntarily, are not unfrequently convulsed; as the diaphragm, intercostals, &c. The more immediate causes of convulsions are, 1. Either mental affection, or any irritating cause exciting a greater action in the arterial system of the brain and nerves. 2. An increase of nervous energy, which seems to hold pace or be equipotent with the increased arterial energy excited in the brain. 3. This increased energy, conveying its augmented effects, without the direction of the will, to any muscles destined to voluntary motion, over-irritates them. 4. The muscles, irritated by the increased nervous energy and arterial influx, contract more forcibly and involuntarily by their excited vis insita, conjointly with other causes, as long as the increased nervous energy continues. 5. This increased energy in the nervous system may be excited either by the mind, or by any acrimony in the blood, or other stimuli sufficiently irritating to increase the arterial action, nervous influence, and the vires insitæ of muscles. 6. After muscles have been once accustomed to act involuntarily, and with increased action, the same causes can readily produce the same effects on those organs. 7. All parts that have muscular fibres may be convulsed. 8. The sensations in the mind most capable of producing convulsions, are timidity, horror, anger, great sensibility of the soul, &c.

Convulsio canina. A wry mouth.

Convulsio cerealis. Cereal convulsion is a singular disorder of the spasmodic convulsive kind, not common to this country, but mentioned by Cartheuser under this title, from the peculiar tingling and formication perceived in the arms and legs. *Motus spasmodicus* of Hoffman. It is endemial in some places in Germany; but more a rural than urbanical disorder, said to arise from the use of spoiled corn.

Convulsio habitualis. St. Vitus's dance. See *Chorea Sancti Viti.*

CONY'ZA. (From κονις, dust; because its powder is sprinkled to kill fleas in places where they are troublesome.) The name of a genus of plants in the Linnæan system. Class, *Syngenesia;* Order, *Polygamia superflua.* There is some difficulty in ascertaing the plants called conyzas by the older practitioners: they are either of the genus conyza, inula, gnaphalium, erigeron, or chrysocoma.

Conyza æthiopica. The plant so called is most probably the *Chrysocoma comaurea* of Willdenow, a shrub which grows wild about the Cape of Good Hope, and is cultivated in our green-houses, because it flowers the greater part of the year.

Conyza cœrulea. The *Erigeron acre* of Linnæus answers to the description of this plant.

Conyza major. Supposed to be the *Inula viscosa* of Linnæus.

Conyza major vulgaris. See *Inula dysenterica.*

Conyza media. See *Inula dysenterica.*

Conyza minor. The *Inula pulicaris* of Linnæus answers to the description given of this plant in most books. Its chief use is to destroy fleas and gnats.

Cooperto′ria. (From *co-operio*, to cover over.) The thyroid cartilage.

Coo′strum. The centre of the diaphragm.

COPA′IBA. (*Copaiba, æ.* fœm. ; from *copal*, the American name for any odoriferous gum, and *iba*, or *iva*, a tree.) The name given by the College of Physicians of London to the balsam of copaiva. See *Copaifera officinalis.*

COPAI′FERA. (From *Copaiva*, the Indian name, and *fero*, to bear.) The name of a genus of plants in the Linnæan system. Class, *Decandria ;* Order, *Monogynia.*

Copaifera officinalis. The systematic name of the plant from which the Copaiba balsam, *Balsamum Braziliense ; Balsamum copaibæ ; Balsamum de copaibu ; Balsamum ; capivi ;* Copaiba ; Capevi ; is obtained.

Copaiba is a yellow resinous juice, of a moderately agreeable smell, and a bitterish biting taste, very permanent on the tongue. The tree which affords it grows in Brazil, New Spain. It is obtained by making deep incisions near its trunk, when the balsam immediately issues, and, at the proper season, flows in such abundance, that sometimes, in three hours, twelve pounds have been procured. The older trees afford the best balsam, and yield it two or three times in the same year. The balsam supplied by the young and vigorous trees, which abound with the most juice, is crude and watery, and is, therefore, accounted less valuable. While flowing from the tree, this balsam is a colourless fluid ; in time, however, it acquires a yellowish tinge, and the consistence of oil ; but though by age it has been found thick, like honey, yet it never becomes solid, like other resinous fluids. By distillation in water, the oil is separated from the resin ; and, in the former, the taste and smell of the balsam are concentrated. If the operation is carefully performed, about one-half of the balsam rises into the receiver, in the form of oil. The balsam unites with fixed and volatile oils, and with spirit of wine. It is given in all diseases of the urinary organs, when no inflammation is present. In gleets, and in gonorrhœa, it was once a favourite remedy, but is now disused. In diseases of the kidneys it is still employed, though less frequently than usual ; and in hæmorrhoids it is occasionally trusted. The dose is from 20 to 30 drops, twice or three times a day, mixed with water, by means of an egg, or any mucilage. The balsam of copaiva is occasionally adulterated with turpentine, but its virtues are not greatly injured by the fraud.

Copaiva. See *Copaiba.*

COPAL. (The American name of all clear odoriferous gums.) Gum copal. This resinous substance is imported from Guinea, where it is found in the sand on the shore. It is a hard shining, transparent, citron-coloured, odoriferous, concrete juice of an American tree, but which has neither the solubility in water common to gums, nor the solubility in alkohol common to resins, at least in any considerable degree. By these properties it resembles amber. It may be dissolved by digestion in linseed oil, rendered drying by quicklime, with a heat very little less than sufficient to boil or decompose the oil. This solution, diluted with oil of turpentine, forms a beautiful transparent varnish, which, when properly applied, and slowly dried, is very hard, and very durable. This varnish is applied to snuff-boxes, tea-boards, and other utensils. It preserves and gives lustre to paintings, and greatly restores the decayed colours of old pictures, by filling up the cracks, and rendering the surfaces capable of reflecting light more uniformly.

Cope′lla. See *Cupel.*

Co′pher. A name for camphor.

CO′PHOS. (Κωφος, dumb.) Deaf or dumb. Also a dulness in any of the senses.

COPHO′SIS. (From κωφος, deaf.) A difficulty of hearing. It is often symptomatic of some disease. See *Dysecœa.*

COPPER. (*Cuprum, i.* neut. *quasi æs Cyprium ;* so named from the island of Cyprus, whence it was formerly brought.) " A metal of a peculiar reddish-brown colour ; hard, sonorous, very malleable and ductile ; of considerable tenacity, and of a specific gravity from 8.6 to 8.9. At a degree of heat far below ignition, the surface of a piece of polished copper becomes covered with various ranges of prismatic colours, the red of each order being nearest the end which has been most heated ; an effect which must doubtless be attributed to oxidation, the stratum of oxide being thickest where the heat is greatest, and growing gradually thinner and thinner towards the colder part. A greater degree of heat oxidizes it more rapidly, so that it contracts thin powdery scales on its surface, which may be easily rubbed off ; the flame of the fuel becoming at the same time of a beautiful bluish-green colour. In a heat, nearly the same as is necessary to melt gold or silver, it melts, and exhibits a bluish-green flame ; by a violent heat it boils, and is volatilised partly in the metallic state.

Copper rusts in the air ; but the corroded part is very thin, and preserves the metal beneath from farther corrosion.

There are two oxides of copper :

1st, The black, procurable by heat, or by drying the hydratic oxide precipitated by potassa from the nitrate. It consists of 8 copper + 2 oxygen. It is a *deutoxide.*

2dly, The *protoxide* is obtained by digesting a solution of muriate of copper with copper turnings, in a close phial. The colour passes from green to dark brown, and grey crystalline grains are deposited. The solution of these yields, by potassa, a precipitate of an orange colour, which is the protoxyde. It consists of 8 copper + 1 oxygen. Protoxyde of copper has been lately found by Mushet, in a mass of copper, which had been exposed to heat for a considerable time, in one of the melting furnaces of the mint under his superintendence.

Copper, in filings, or thin laminæ, introduced into chlorine, unites with flame into the chloride, of which there are two varieties ; the protochloride, a fixed yellow substance, and the deutochloride, a yellowish-brown pulverulent sublimate.

1. The crystalline grains deposited from the above muriatic solution, are *protpchloride.* The protochloride is conveniently made by heating together two parts of corrosive sublimate, and one of copper filings. An amber-coloured translucent substance, first discovered by Boyle, who called it resin of copper, is obtained. It is fusible at a heat just below redness ; and in a close vessel, or a vessel with a narrow orifice, is not decomposed or sublimed by a strong red heat. But if air be admitted, it is dissipated in dense white fumes. It is insoluble in water. It effervesces in nitric acid. It dissolves silently in muriatic acid, from which it may be precipitated by

water. By slow cooling of the fused mass, Dr. John Davy obtained it crystallised, apparently in small plates, semi-transparent, and of a light yellow colour. It consists, by the same ingenious chemist, of

Chlorine,	36	or 1 prime =	4.45	35.8
Copper,	64	or 1 prime	8.00	64.2
	100		12.45	100.0

2. *Deutochloride* is best made by slowly evaporating to dryness, at a temperature not much above 400° Fahr. the deliquescent muriate of copper. It is a yellow powder. By absorption of moisture from the air, it passes from yellow to white, and then green, reproducing common muriate. Heat converts it into protochloride, with the disengagement of chlorine. Dr. Davy ascertained the chemical constitution of both these compounds, by separating the copper with iron, and the chlorine by nitrate of silver. The deutochloride consists of

Chlorine,	53	2 primes	8.9	52.7
Copper,	47	1 do.	8.0	47.3
	100		16.9	100.0

The *iodide* of copper is formed by dropping aqueous hydriodate of potassa into a solution of any cupreous salt. It is an insoluble dark brown powder.

Phosphuret of copper is made by projecting phosphorus into red-hot copper.

Sulphuret of copper is formed by mixing together eight parts of copper filings, and two of sulphur, and exposing the mixture to a gentle heat.

The sulphuric acid, when concentrated and boiling, dissolves copper.

Nitric acid dissolves copper with great rapidity, and disengages a large quantity of nitrous gas. Part of the metal falls down in the form of an oxide; and the filtrated or decanted solution, which is of a much deeper blue colour than the sulphuric solution; affords crystals by slow evaporation. This salt is deliquescent, very soluble in water, but most plentifully when the fluid is heated.

The saline combinations of copper were formerly called *sales veneris*, because Venus was the mythological name of copper. They have the following general characters:

1. They are mostly soluble in water, and their solutions have a green or blue colour, or acquire one of these colours on exposure to air.

2. Ammonia added to the solutions, produces a deep blue colour.

3. Ferroprussiate of potassa gives a reddish-brown precipitate, with cupreous salts.

4. Gallic acid gives a brown precipitate.

5. Hydrosulphuret of potassa gives a black precipitate.

6. A plate of iron immersed in these solutions throws down metallic copper, and very rapidly if there be a slight excess of acid. The protoxide of copper can be combined with the acids only by very particular management. All the ordinary salts of copper have the peroxide for a base.

The joint agency of air and acetic acid, is necessary to the production of the cupreous *acetates*. By exposing copper plates to the vapours of vinegar, the bluish-green *verdigris* is formed, which, by solution in vinegar, constitutes *acetate of copper*.

Arseniate of copper presents us with many subspecies which are found native. The arseniate may be formed artificially by digesting arsenic acid on copper, or by adding arseniate of potassa to a cupreous saline solution.

Carbonate of copper. Of this compound there are three native varieties, the green, the blue, and the anhydrous.

Chlorate of copper is a deflagrating deliquescent green salt.

Fluate of copper is in small blue-coloured crystals.

Hydriodate of copper is a greyish-white powder.

Protomuriate of copper has already been described in treating of the chlorides.

Deutomuriate of copper, formed by dissolving the deutoxide in muriatic acid, or by heating muriatic acid on copper filings, yields by evaporation crystals of a grass-green colour.

The *ammonia-nitrate* evaporated, yields a fulminating copper. Crystals of nitrate, mixed with phosphorus, and struck with a hammer, detonate.

Subnitrate of copper is the blue precipitate, occasioned by adding a little potassa to the neutral nitric solution.

Nitrate of copper is formed by mixing nitrate of lead with sulphate of copper.

The *sulphate*, or blue vitriol of commerce, is a bisulphate.

A mixed solution of this sulphate and sal-ammoniac, forms an ink, whose traces are invisible in the cold, but become yellow when heated: and vanish again as the paper cools.

Protosulphite of copper is formed by passing a current of sulphurous acid gas through the deutoxide of copper diffused in water. It is deprived of a part of its oxygen, and combines with the acid. The sulphate, simultaneously produced, dissolves in the water; while the sulphite forms small red crystals, from which merely long ebullition in water expels the acid.

Sulphite of potassa and copper is made by adding the sulphite of potassa to nitrate of copper. A yellow flocculent precipitate, consisting of minute crystals, falls.

Ammonia-sulphate of copper is the salt formed by adding water of ammonia to solution of the bisulphate. It consists, according to Berzelius, of 1 prime of the cupreous, and 1 of the ammoniacal sulphate, combined together; or 20.0+7.13+14.625 of water.

Subsulphate of ammonia and copper is formed by adding alcohol to the solution of the preceding salt, which precipitates the subsulphate. It is the *cuprum ammoniacum* of the pharmacopœia.

Sulphate of potassa and copper is formed by digesting bisulphate of potassa on the deutoxide or carbonate of copper.

The following acids, antimonic, antimonious, boracic, chromic, molybdic, phosphoric, tungstic, form insoluble salts with deutoxide of copper. The first two are green, the third is brown, the fourth and fifth green, and the sixth white. The benzoate is in green crystals, sparingly soluble. The oxalate is also green. The binoxalates of potassa and soda, with oxide of copper, give triple salts, in green needle-form crystals. There are also ammonia-oxalates in different varieties. Tartrate of copper forms dark bluish-green crystals. Cream-tartrate of copper is a bluish-green powder, commonly called Brunswick green.

To obtain pure copper for experiments, we precipitate it in the metallic state, by immersing a plate of iron in a solution of the deutomuriate. The pulverulent copper must be washed with dilute muriatic acid.

This metal combines very readily with *gold*, *silver*, and *mercury*. It unites imperfectly with *iron* in the way of fusion. *Tin* combines with copper, at a temperature much lower than is necessary to fuse the copper alone. On this is grounded the method of tinning copper vessels. For this purpose, they are first scraped or scoured; after which they are rubbed with sal-ammoniac. They are then heated, and sprinkled with powdered resin, which defends the clean surface of the copper from acquiring the slight film of oxide that would prevent the adhesion of the tin to its surface. The melted tin is then poured in, and spread about. An extremely small quantity adheres to the copper, which may perhaps be supposed insufficient to prevent the noxious effects of the copper as perfectly as might be wished

When tin is melted with copper, it composes the compound called *bronze.*

Copper unites with *bismuth*, and forms a reddish-white alloy. With *arsenic* it forms a white brittle compound, called tombac. With *zinc* it forms the compound called brass, and distinguished by various other names, according to the proportions of the two ingredients.

Copper unites readily with antimony, and affords a compound of a beautiful violet colour. It does not readily unite with *manganese*. With *tungsten* it forms a dark brown spongy alloy, which is somewhat ductile.

Verdigris, and other preparations of copper, act as virulent poisons, when introduced in very small quantities into the stomachs of animals. A few grains are sufficient for this effect. Death is commonly preceded by very decided nervous disorders, such as convulsive movements, tetanus, general insensibility, or a palsy of the lower extremities. This event happens frequently so soon, that it could not be occasioned by inflammation or erosion of the *primæ viæ;* and indeed, where these parts are apparently sound. It is probable that the poison is absorbed, and, through the circulation, acts on the brain and nerves. The cupreous preparations are no doubt very acrid, and if death do not follow their immediate impression on the sentient system, they will certainly inflame the intestinal canal. The symptoms produced by a dangerous dose of copper are exactly similar to those which are enumerated under arsenic, only the taste of copper is strongly felt. The only chemical antidote to cupreous solutions, whose operation is well understood, is water strongly impregnated with sulphuretted hydrogen. The alkaline hydrosulphurets are acrid, and ought not to be prescribed.

But we possess, in sugar, an antidote to this poison, of undoubted efficacy, though its mode of action be obscure. Duval introduced into the stomach of a dog, by means of a caoutchouc tube, a solution in acetic acid, of four French drachms of oxide of copper. Some minutes afterwards he injected into it four ounces of strong syrup. He repeated this injection every half-hour, and employed altogether 12 ounces of syrup. The animal experienced some tremblings and convulsive movements. But the last injection was followed by a perfect calm. The animal fell asleep, and awakened free from any ailment.

Orfila relates several cases of individuals who had by accident or intention swallowed poisonous doses of acetate of copper, and who recovered by getting large doses of sugar. He uniformly found, that a dose of verdigris which would kill a dog in the course of an hour or two, might be swallowed with impunity, provided it was mixed with a considerable quantity of sugar.

As alcohol has the power of completely neutralizing, in the æthers, the strongest muriatic and hydriodic acids, so it would appear that sugar can neutralize the oxides of copper and lead. The neutral saccharite of lead, indeed, was employed by Berzelius in his experiments, to determine the prime equivalent of sugar. If we boil for half an hour, in a flask, an ounce of white sugar, an ounce of water, and 10 grains of verdigris, we obtain a green liquid, which is not affected by the nicest tests of copper, such as ferroprussiate of potassa, ammonia, and the hydrosulphurets. An insoluble green carbonate of copper remains at the bottom of the flask."—*Ure's Chem. Dict.*

Copper, ammoniated solution of. See *Cupri ammoniati liquor.*

CO'PPERAS. A name given to blue, green, and white vitriol.

COPRAGO'GA. (From *κοπρος*, dung, and *αγω*, to bring away.) Purgatives. *Copragogum* is the name of a gently-purging electuary, mentioned by Rulandus.

COPRIE'MESIS. (From *κοπρος*, excrement, and *εμεω*, to vomit.) A vomiting of fæces.

COPROCRI'TICA. (From *κοπρος*, excrement, and *κρινω*, to separate.) Mild cathartic medicines.

COPROPHO'RIA. (From *κοπρος*, excrement, and *φορεω*, to bring away.) A purging.

CO'PROS. Κοπρος. The fæces, or excrements from the bowels.

COPROSTA'SIA. (From *κοπρος*, fæces, and *ιϛημι*, to remain.) Costiveness, or a constriction of the belly.

COPTA'RIOM. (Κοπτη, a small cake.) *Coptarium.* A lozenge.

CO'PTE. (Κοπτη, a small cake.) 1. The form of a medicine used by the ancients.

2. A cataplasm generally made of vegetable substances, and applied externally to the stomach, and on many occasions given internally.

CO'PULA. (*Quasi compula;* from *compello*, to restrain.) A name for a ligament.

COQUE'NTIA. (From *coquo*, to digest.) Medicines which promote concoction.

COR. (*Cor, dis.* neut.)

1. The heart. See *Heart.*

2. Gold.

3. An intense fire.

CORACI'NE. (From *κοραξ*, a crow; so named from its black colour.) A name for a lozenge, quoted by Galen from Asclepiades.

CORACO. The first part of the name of some muscles which are attached to the coracoid process of the blade-bone.

CORACO-BRACHIALIS. *Coraco-humeral* of Dumas. *Coraco-brachiæus.* A muscle, so called from its origin and insertion. It is situated on the humerus, before the scapula. It arises, tendinous and fleshy, from the fore-part of the coracoid process of the scapula, adhering, in its descent, to the short head of the biceps; inserted, tendinous and fleshy, about the middle of the internal part of the os humeri, near the origin of the third head of the triceps, called *brachialis externus*, where it sends down a thin tendinous expansion to the internal condyle of the os humeri. Its use is to raise the arm upwards and forwards.

CORACO HYOIDEUS. See *Omo hyoideus.*

CO'RACOID. (*Coracoideus;* from *κοραξ*, a crow, and *ειδος*, resemblance: shaped like the beak of a crow.) Some processes of the bones are so named which were supposed to resemble the beak of a crow.

CORACOID PROCESS. *Processus coracoides.* See *Scapula.*

CO'RAL. See *Corallium.*

CORALLI'NA. (Diminutive of *corallium.*)

Muscus maritimus; Corallina officinalis; Corallina alba. Sea coralline; Sea moss; White wormseed. A marine production, or fucus, resembling a small plant without leaves, consisting of numerous brittle cretaceous substances, friable betwixt the fingers, and crackling between the teeth. Powdered, it is administered to children as an anthelminthic, in the dose of half a drachm to a drachm once or twice a day.

CORALLINA CORSICANA. *Helmintho-corton; Conferva helmintho-cortos; Corallina rubra; Corallina melito-corton; Lemitho-corton; Mouse de Corse.* Corsican worm-weed. *Fucus helmintho-corton* of De la Tourrette. This plant has gained great repute in destroying all species of intestinal worms. Its virtues are extolled by many; but impartial experimentalists have frequently been disappointed of its efficacy. The Geneva Pharmacopœia directs a syrup to be made of it.

CORALLINA MELITO-CORTON. See *Corallina corsicana.*

CORALLINA RUBRA. See *Corallina corsicana.*

CORALLINE. See *Corallina.*

Coralline, Corsican. See *Corallina corsicana.*

CORA'LLIUM. (*Corallium, i.* n.; from κορη, a daughter, and αλς, the sea, because it is the production of the sea.) Coral.

CORALLIUM ALBUM. A hard, white, calcareous brittle substance; the nidus of the *Madrepora oculata.* Class, *Vermes;* Order, *Lithophyta.* It is sometimes exhibited as an absorbent earth.

CORALLIUM RUBRUM. *Acmo. Azur.* The red coral is mostly employed medicinally. It is a hard, brittle, calcareous substance, resembling the stalk of a plant, and is the habitation of the *Isis nobilis.* Class, *Vermes;* Order, *Zoophyta.* When powdered, it is exhibited as an absorbent earth to children; but does not appear to claim any preference to common chalk.

CORALLODE'NDRON. (From κοραλλιον, coral, and δενδρον, a tree, resembling in hardness and colour a piece of coral.) The coral-tree of America; antivenereal.

CORALLOI'DES. (From κοραλλιον, coral, and ειδος, likeness.) Coral-like. See *Clavaria coralloides.*

CO'RCHORON. (From κορη, the pupil of the eye, and κορεω, to purge; so called because it was thought to purge away rheum from the eyes.) The herb pimpernel, or chickweed.

CORCULUM. (*Corculum*, a little heart; diminutive of *cor*, a heart.) An essential part of a germinating seed, called also the *embryo*, or germ. It lies between the cotyledons. It is the point from which the life and organisation of the future plant originate. In some seeds it is much more conspicuous than in others. The walnut, bean, pea, and lupine, show it in perfection. Its internal structure, before it begins to vegetate, is observed to be very simple, consisting of a uniformly medullary substance, enclosed in its appropriate bark or skin. Vessels are formed in it as soon as the vital principle is excited to action, and parts are then developed which seemed not previously to exist. There are observed in it,

1. The *rostellum*, or little beak, which penetrates into the earth and becomes the root.

2. The *plumula*, which shoots above the ground, and becomes a tuft of young leaves, with which the young stem, if there be any, ascends. See *Cotyledon.*

CO'RDA. See *Chorda.*

CORDA TYMPANI. See *Chorda tympani.*

CORDA WILLISII. See *Dura mater.*

CORDATUS. Heart-shaped. Applied to leaves, petals, &c. which are ovate, hollowed out at the base, according to the vulgar idea of a heart: a form very frequent in leaves; as in those of *Arcticum lappa*, and *Tamus communis*, and the petals of the *Sium selinum.*

A leaf is called *obcordate*, when the apex of the heart-shaped leaf is fixed to the petiole.

CO'RDIA. (So called by Plumier in honour of Euricius Cordius and his son Valerius, two eminent German botanists.) The name of a genus of plants. Class, *Pentandria;* Order, *Monogynia.*

CORDIA MYXA. The systematic name of the Sebesten plant. *Sebesten; Sebestina; Cordia—foliis ovatis, supra glabris; corymbis lateralibus; calycibus decemstriatis* of Linnæus. The dark black fruit possesses glutinous and aperient qualities, and is exhibited in form of decoction in various diseases of the chest, hoarseness, cough, difficult respiration, &c.

CORDIAL. *Cardiacus.* Medicines are generally so termed, which possess warm and stimulating properties, and that are given to raise the spirits.

CORDINE'MA. (From καρα, the head, and δινεω, to move about.) A headache attended with a vertigo.

CORDO'LIUM. (From *cor*, the heart, and *dolor*, pain.) A name formerly applied to cardialgia, or heart-burn.

CORDUS, VALERIUS, was born in 1515, of a Hessian family. After studying in some of the German universities, he travelled through Italy, chiefly engaged in botanical researches. He died at the early age of 29, leaving several works; a "History of Plants," many of them never before described; "Annotations on Dioscorides;" a Nuremberg Dispensatory, &c.

CO'RE. Κορη. The pupil of the eye.

CORE'MATA. (From κορεω, to cleanse.) Medicines for cleansing the skin.

CORIACEUS. Leathery. Applied to leaves and pods that are thick and tough without being pulpy, or succulent; as in the leaves of *Magnolia grandiflora, Aucuba,* &c. and the pods of the Lupin.

CORIANDER. See *Coriandrum.*

CORIA'NDRUM. (*Coriandrum, i.* n.; from κορη, a pupil, and ανηρ, a man: because of its roundness, like the pupil of a man's eye; or probably so called from κορις, *cimex*, a bug, because the green herb, seed and all, stinks intolerably of bugs.) Coriander.

1. The name of a genus of plants in the Linnæan system. Class, *Pentandria;* Order, *Dygynia.*

2. The pharmacopœial name of the officinal coriander. See *Coriandrum sativum.*

CORIANDRUM SATIVUM. The systematic name of the plant called *coriandrum* in the pharmacopœias. *Cassibor; Corianon.* The *Coriandrum—fructibus globosis*, of Linnæus. This plant is a native of the South of Europe, where, in some places, it is said to grow in such abundance as frequently to choke the growth of wheat and other grain. From being cultivated here as a medicinal plant, it has for some time become naturalized to this country, where it is usually found in corn fields, the sides of roads, and about dunghills. Every part of the plant, when fresh, has a very offensive odour, but upon being dried, the seeds have a tolerably grateful smell, and their taste is moderately warm and slightly pungent. They give out their virtue totally to rectified spirit, but only partially to water. In distillation with water, they yield a small quantity of a yellowish essential oil, which smells strongly and pretty agreeably of the coriander.

Dioscorides asserts, that the seeds, when taken in a considerable quantity, produce deleterious effects; and, in some parts of Spain and Egypt, where the fresh herb is eaten as a cordial, instances of fatuity, lethargy, &c. are observed to occur very frequently; but these qualities seem to have been unjustly ascribed to the coriander; and Dr. Withering informs us, that he has known six drachms of the seeds taken at once, without any remarkable effect. These seeds, and indeed most of those of the umbelliforous plants, possess a stomachic and carminative power. They were directed in the infusum amarum, the infusum sennæ tartarizatum, and some other compositions of the pharmacopœias; and according to Dr. Cullen, the principal use of these seeds is, "that infused along with senna, they more powerfully correct the odour and taste of this than any other aromatic that I have employed, and are, I believe, equally powerful in obviating the griping that senna is very ready to produce."

CORIA′NON. See *Coriandrum*.

CO′RIS. (From κειρω, to cleave, or cut; so called because it was said to heal wounds.) The herb St. John's wort. See *Hypericum*.

CORIS CRETICA. See *Hypericum Saxatile*.

CORIS LUTEA. See *Hypericum Coris*.

CORIS MONSPELIENSIS. *Symphetum pætreum*. Heath pine. This plant is intensely bitter and nauseous, but apparently, an active medicine, and employed, it is said, with success in syphilis.

CORK. *Suber*. The bark of the *Quercus suber* of Linnæus, formerly employed as an astringent, but now disused. By the action of nitric acid it is acidified. See *Suberic acid*.

Cork has been recently analyzed by Chevreuil by digestion, first in water and then in alkohol. By distillation there came over an aromatic principle, and a little acetic acid. The watery extract contained a yellow and a red colouring matter, an undetermined acid, gallic acid, an astringent substance, a substance containing azot, a substance soluble in water and insoluble in alkohol, gallate of iron, lime, and traces of magnesia. 20 parts of cork treated in this way, left 17.15 of insoluble matter. The undissolved residue being treated a sufficient number of times with alkohol, *yielded* a variety of bodies, but which seem reducible to three; namely, *cerin*, resin, and an oil. The ligneous portion of the cork still weighed 14 parts, which are called *suber*.

Cork, fossil. See *Asbestos*.

CORN. *Clavus*. A hardened portion of cuticle, produced by pressure: so called because a piece can be picked out like a corn of barley.

Corn salad. See *Valeriana locusta*.

CORNACHINI PULVIS. Scammony, antimony, and cream of tartar.

CORNARIUS, JOHN, was born in Upper Saxony, in the year 1500. According to Haller his real name was Haguenbot, or Hanbut. He is said to have been led to the study of medicine from the delicacy of his own constitution. He graduated at Padua, after attending several other universities. Besides translating Hippocrates, and some other Greek writers into Latin, he was author of several works on medicine; and is said to have had an extensive practice. He died in 1558, leaving a son, DIOMEDE, who succeeded him, and was afterwards professor of medicine at Vienna, and physician to Maximilian II.

CORNARO, LEWIS, of a noble Venetian family, was born in 1467. Having impaired his constitution by a debauched and voluptuous life, and brought on at last a severe illness; on recovering from this, at the age of more than 40, he adopted a strict, abstemious regimen, limiting himself to twelve ounces of solid food, and fourteen of wine, daily; which quantity he rather diminished in the latter part of his life. He carefully avoided also the extremes of heat or cold, with all violent exercise; and took care to live in a pure dry air. He thus preserved a considerable share of health and activity to the great age of 98. His wife, by whom he had an only child, a daughter, when they were both advanced in years, survived him, and attained nearly the same period. When he was 83, he published a short treatise in commendation of temperance, which has been repeatedly translated, and printed in every country of Europe. He then states himself to have been able to mount his horse, without assistance, from any rising ground. He wrote three other discourses on similar subjects at subsequent periods, the last, only three years before his death. The best English translation is said to be that of 1779.

CO′RNEA. The sclerotic membrane of the eye is so called, because it is of a horny consistence. See *Sclerotic coat*.

CORNEA OPACA. See *Sclerotic coat*.

CORNEA TRANSPARENS. *Sclerotica ceratoides*. The transparent portion of the sclerotic membrane, through which the rays of light pass, is so called, to distinguish it from that which is opaque. See *Sclerotic coat*.

CORNE′STA. A chemical retort.

CORNFLOWER. See *Centaurea Cyanus*.

CORNI′CULA. (From *cornu*, a horn.) A cupping instrument, made of horn.

CORNICULA′RIS. (From *cornu*, a horn.) Shaped like a horn; the coracoid process of the scapula.

CORNIFORMIS. (From *cornu*, a horn, and *forma*, resemblance.) Horn-shaped: applied to the nectary of plants:—*nectarium corniforme*, in the orchis tribe.

CO′RNU. A horn. This term is used both in anatomy, surgery, and materia medica. 1. A wart. See *Verruca*.

2. A corn or horny induration of the cuticle. See *Corn*.

3. The horn of the stag.

4. The cavities of the brain.

CORNU AMMONIS. *Cornu arietis*. When, the pes hippocampi of the human brain is cut transversely through, the cortical substance is so disposed as to resemble a ram's horn. This is the true cornu ammonis, though the name is often applied to the *pes hippocampi*.

CORNU ARIETIS. See *Cornu ammonis*.

CORNU CERVI. Hartshorn. The horns of several species of stag, as the *Cervus alces*, *Cervus dama*, *Cervus elaphus*, and *Cervus taranda*, are used medicinally. Boiled, they impart to the water a nutritious jelly, which is frequently served at table. Hartshorn jelly is made thus: —Boil half a pound of the shavings of hartshorn, in six pints of water, to a quart; to the strained liquor add one ounce of the juice of lemon, or of Seville orange, four ounces of mountain wine and half a pound of sugar; then boil the whole to a proper consistence. The chief use of the horns is for calcination, and to afford the *liquor volatilis cornu cervi* and subcarbonate of ammonia.

CORNU CERVI CALCINATUM. See *Cornu ustum*.

CORNU USTUM. *Cornu cervi calcinatum*. Burn pieces of hartshorn in an open fire, till they become thoroughly white; then powder, and prepare them in the same manner as is directed for chalk. Burnt hartshorn shavings possess absorbent, antacid, and adstringent properties, and are given in the form of decoction, as a common drink in diarrhœas, pyrosis, &c.

CORNUA UTERI. *Plectenæ.* In comparative anatomy, the horns of the womb: the womb being in some animals trianguler, and its angles resembling horns.

CORNUMU'SA. A retort

CO'RNUS. 1. The name of a genus of plants in the Linnæan system. Class, *Tetrandria;* Order, *Monogynia*.

2. The pharmacopœial name of the cornel-tree. See *Cornus sanguinea.*

CORNUS SANGUINEA. The fruit is moderately cooling and astringent.

CORNU'TA. (From *cornu;* from its resemblance to a horn.) A retort.

COROLLA. (From *coronula,* a little crown.) The leaves of a flower which consist of those more delicate and dilated, generally more coloured leaves, which are always internal with respect to the calyx, between it and the internal organs of the flower, and which constitute its chief beauty. It always consists of one or more coloured leaves, which are termed *petals.*

A coloured calyx is to be distinguished from a corolla, which may be readily done in the *Allyssum alpestre,* and *Lamium orvala.*

There are four general divisions of corols.

1. *Monopetalous,* which consists of one petal, as in *Nicotiana tabacum.*

2. *Polypetalous,* having many; as in *Lillium candidum.*

3. *Compound,* consisting of many corolla, which are not calyculated, and are on a common receptacle and calyx; as in *Helianthus annuus.*

4. *Aggregate,* consisting of many calyculated corolla placed on a common calyx; as in *Scabiosa arvensis,* and *Echinops sphærocephalus.*

A. *Corolla monopetala,* formed of one petal, which, for the most part, forms a cavity, and is divided into,

a. *Limbus,* the limb, which is the margin, or horizontal spreading portion.

b. *Tubus,* the tube, which is the cylindrical and inferior part, and is enclosed in the calyx.

c. *Fauces,* or the orifice of the tube.

From the figure of a regular or uniform limb are derived the following terms:

1. *Corolla campanulata,* bell-shaped; as in *Campanula* and *Atropa.*

2. *C. globosa,* globular; as in *Hyacinthus botryoides* and *Erica ramentacea.*

3. *C. Tubulosa,* tubular, as in *Primula* and *Erica Massoni.*

4. *C. claviculata;* as in *Erica tubiflora.*

5. *C. cyathiformis,* cup-shaped; as in *Sympathum officinale.*

6. *C. infundibuliformis,* funnel-shaped; as in *Nicotiana tabacum,* and *Datura stramonium.*

7. *C. hypocrateriformis,* salver-shaped, a flat limb upon a long tube; as in *Vinca rosea.*

8. *C. rotata:* wheel-shaped, that is salver-shaped, with scarcely any tube; as in *Borago officinalis,* and *Physalis alkekengi.*

9. *C. urceolata,* saucer-like; as in *Evolvulus alcinoides.*

10. *C. contorta,* obliquely bent; as in *Vinca minor,* and *Nerium oleander.*

11. *C. ligulata,* the tube very short, and ending suddenly in an oblong petal; as in the corolla of the radius of the *Helianthus annuus.*

From the figure of an *unequal limb:*

1. *Corolla ringens,* irregular and gaping like the mouth of an animal; as in *Lamium album,* and *Salvia sclarea.*

2. *C. personata,* irregular and closed by a kind of palate; as in *Antirrhinum majus.*

In the ringent and personate corollæ are to be noticed the following parts:

a. *Tubus,* the inferior part.

b. *Rictus,* the space between the two lips.

c. *Faux,* the orifice of the tube in the rectus.

d. *Galea,* the helmet or superior arched lip.

e. *Labellum* or *barba,* the inferior lip.

f. *Palatum,* the palate, an eminence in the inferior lip which shuts the rictus of a personate corolla.

g. *Calcar,* the spur which forms an obtuse or acute bag at the side of the receptacle.

3. *C. bilabiata,* two-lipped, the tube divided into two irregular lips opposite each other, without any visible rictus; as in *Aristolochia bilabiata.*

In the bilabiate corolla are to be noticed,

a. The *tubus.*

b. The *faux.*

c. The *superior lip,* formed of one or two lobes.

d. The *inferior lip,* mostly three-lobed.

e. *One-lipped,* the upper or lower wanting, as in *Aristolochia clematitis,* and *Teucrium.*

Corolla infera, means that it is below the germen, which is the most common place of the corolla; and *corolla supera,* above the germen, as in roses.

B. *Corolla polypetala,* formed of many petals.

In the petal of this division are noticed,

a. The *unguis,* the claw, the thin inferior part.

b. The *lamina* or border, the broader and superior part; example, *Dianthus caryophyllus.*

From the *number* of *uniform* petals, the corol of this division is named,

1. *Dipetalous;* as in *Euphorbia graminea.*

2. *Tripetalous;* as in *Tradescantia virginica.*

3. *Tetrapetalous;* as in *Chieranthus incanus.*

4. *Pentapetalous;* as in *Pæonia officinalis.*

5. *Hexapetalous;* as in *Lilium candidum.*

6. *Polypetalous;* as in *Rosa centifolia.*

From the *figure,*

1. *Malvaceous;* pentapetalous, with its claws united laterally, so that it appears monopetalous; as in *Malva sylvestris,* and *Alcea.*

2. *Rosaceus,* spreading like a rose, pentapetalous, almost destitute of claws; as in *Rosa canina,* and *Pæonia officinalis.*

3. *Liliaceous;* six-petalled, sometimes three without a calyx; as in *Lilium candidum.*

4. *Caryophyllaceous;* five petalled, with a long claw, spreading border, and a monophyllous tubular calyx; as in *Dianthus caryophyllus,* and *Saponaria officinalis.*

5. *Cruciform;* three-petalled, like a cross; as in *Sinapis alba,* and *Lunaria alba.*

6. *Manifold,* many corols lying one on another; as in *Cactus flagelliformis.*

From the *figure* of *unequal petals:*

1. *Orchideal,* five petals, three of which are bent backward, and two are lateral and in the middle of these: the labellum is bent back on the nectary.

2. *Papilionaceous,* four petals, irregular and spreading somewhat like a butterfly; as in *Lathyrus latifolius,* and *Robinii pseudacacia.*

In a *papilionaceons* corolla, observe,

a. The *vexillum,* the standard or large concave one at the bark.

b. *Alæ,* the wings or two side-petals, placed in the middle.

c. The *carina,* or keel, consisting of two petals, united or separate, embracing the internal organs.

3. *Calcarate* or spurred, pentapetalous, one petal formed into a spur-like tube.

C. *Compound corolla;* consisting of numerous florets; not calyculate, and within a common perianthium.

It affords,

a. The *discus*, disk, or middle.

b. The *radius*, which forms the circumference. The marginal white florets of the daisy exemplify the rays, and the central yellow ones the disk.

From the difference in the florets of a compound flower it is said to be,

a. *Tubulate*, when all the florets are cylindrical.

b. *Ligulate* or *semiflosculose*, shaped like a strap or ribband; as in *Leontodon taraxacum*.

c. *Radiate*, if the florets in the radius are ligulate, and those in the disk tubular.

d. *Semiradiate*, the radius consisting of only a few ligulate florets on one side; as in *Bidens*. See also *Petala*.

COROLLULA. (A diminutive of *corolla*, a little wreath or crown.) The partial petal, or floret of a compound flower.

CORO'NA. A crown. This term is used in anatomy to designate the basis of some parts; and in botany, to parts of plants, from their resemblance. In the writings of some botanists it is synonymous with *radius*.

Corona ciliaris. The ciliar ligament.

Corona glandis. The margin of the glans penis.

Corona imperialis. A name for crown imperial. The Turks use it as an emetic. The whole plant is poisonous.

Corona regia. The melilotus.

Corona solis. See *Helianthus annuus*.

Corona veneris. Venereal blotches on the forehead are so termed.

CORONAL. (*Coronalis;* from *corona*, a crown or garland.) Belonging to a crown or garland: so named because the ancients wore their garlands in its direction.

Coronal suture. *Sutura coronalis; Sutura arcualis*. The suture of the head, that extends from one temple across to the other, uniting the two parietal bones with the frontal.

CORONA'RIUS. See *Coronary*.

Coronariæ. The name of an order of plants in Linnæus's Fragments of a Natural Method, consisting of such as have beautiful flowers, thus forming a floral crown.

CORONARY. (*Coronarius;* from *corona*, a crown.) This term is applied to vessels and nerves, which supply the corona or basis of parts, or because they spread round the part like a garland or crown.

Coronary ligaments. (From *corona*, a crown.) Ligaments uniting the radius and ulna. The term ligamentum coronarium is also applied to a ligament of the liver.

Coronary vessels. *Vasa coronaria*. The arteries and veins of the heart and stomach.

CORONATUS. Little crown-like eminences on the surface of the petal; or in *Nerium oleander*.

Coronati. *Coronaticus*. The name of a class of plants in Linnæus's Fragments, of a Natural Method, consisting of plants which have the seed-bud placed under the flower-cup which serves it for a crown.

CORO'NE. (Κορωνη, a crow: so named from its supposed likeness to a crow's bill.) The acute process of the lower jaw-bone.

CORONOID. (*Coronoideus;* from κορωνη, a crow, and ειδος, likeness.) Processes of bones are so called, that have any resemblance to a crow's beak; as coronoid process of the ulna, jaw, &c.

CORONO'PUS. (From κορωνη, a carrion crow, and πους, a foot; the plant being said to resemble a crow's foot.) See *Plantago*.

CORONULA. The hem or border which surrounds the seeds of some flowers in the form of a crown.

CO'RPUS. 1. The body. See *Body*.

2. Many parts and substances are also distinguished by this name; as *corpus callosum, corpus luteum*, &c.

Corpus albicans. Two white eminences in the basis of the brain, discovered by Willis, and called *corpora albicantia Willisii*.

Corpus annulare. A synonym of the pons Varolii. See *Pons Varolii*.

Corpus callosum. *Commissura magna cerebri*. The white medullary part joining the two hemispheres of the brain, and coming into view under the falx of the duramater when the hemispheres are drawn from each other. On the surface of the *corpus callosum* two lines are conspicuous, called the *raphe*.

Corpus cavernosus clitoridis. See *Clitoris*.

Corpus cavernosus penis. See *Penis*.

Corpus fimbriatum. The flattened terminations of the posterior crura of the fornix of the brain, which turn round into the inferior cavity of the lateral ventricle, and end in the *pedes hippocampi*.

Corpus glandulosum. The prostate gland.

Corpus lobosum. Part of the cortical part of the kidney.

Corpus luteum. A yellow spot found in that part of the ovarium of females, from whence an ovum has proceeded; hence their presence determines that the female has been impregnated. The number of the *corpora lutea* corresponds with the number of impregnations. It is, however, asserted by a modern writer, that *corpora lutea* have been detected in young virgins, where no impregnations could possibly have taken place.

Corpus mucosum. See *Rete mucosum*.

Corpus nerveo-spongiosum. The cavernous substance of the penis.

Corpus nervosum. The cavernous substance of the clitoris.

Corpus olivare. Two external prominences of the medulla oblongata, shaped somewhat like an olive, are called corpora olivaria.

Corpus pampiniforme. Applied to the spermatic chord, and thoracic duct; also to the plexus of the veins surrounding the spermatic artery in the cavity of the abdomen.

Corpus pyramidale. Two internal prominences of the medulla oblongata, which are of a pyramidal shape, are called corpora pyramidalia.

Corpus quadrigeminum. See *Tubercula quadrigemina*.

Corpus reticulare. See *Rete mucosum*.

Corpus sesamoideum. A little prominence at the entry of the pulmonary artery.

Corpus spongiosum urethræ. *Substantia spongiosa urethræ. Corpus spongiosum penis*. This substance originates before the prostate gland, surrounds the urethra, and forms the *bulb;* then proceeds to the end of the corpora cavernosa, and terminates in the *glans penis*, which it forms.

Corpus striatum. So named from its appearance. See *Cerebrum*.

Corpus varicosum. The spermatic chord.

Corra'go. (From *cor*, the heart; it being supposed to have a good effect in comforting the heart.) See *Borago officinalis.*

Co'rre. (From κειρω, to shave.) The temples. That part of the jaws where the beard grows, and which it is usual to shave.

CORROBORANT. (*Corroborans.*) Whatever gives strength to the body; as bark, wine, beef, cold-bath, &c. See *Tonic.*

CORROSIVE. (*Corrosivus; from corrodo,* to eat away.) See *Escharotic.*

Corrosive sublimate. The oxymuriate of mercury. See *Hydrargyri oxymurias.*

CORRUGA'TOR. (From *corrugo,* to wrinkle.) The name of muscles, the office of which is to wrinkle or corrugate the parts they act on.

Corrugator supercilii. A small muscle situated on the forehead. *Musculus supercilii* of Winslow; *Musculus frontalis verus, seu corrugator coiterii* of Douglas; and *Cutanio sourcillier* of Dumas. When one muscle acts, it is drawn towards the other, and projects over the inner canthus of the eye. When both muscles act, they pull down the skin of the forehead, and make it wrinkle, particularly between the eyebrows.

CO'RTEX. (*Cortex, icis.* m. or f.) This term is generally, though improperly, given to the Peruvian bark. It applies to any rind, or bark.

Cortex angelinæ. The bark of a tree growing in Grenada. A decoction of it is recommended as a vermifuge. It excites tormina, similar to jalap, and operates by purging.

Cortex angusturæ. See *Cusparia.*

Cortex antiscorbuticus. The canella alba. See *Winteria aromatica.*

Cortex aromaticus. See *Winteria aromatica.*

Cortex bela-aye. See *Nerium anti-dysentericum.*

Cortex canellæ malabaricæ. See *Laurus cassia.*

Cortex cardinalis de lugo. The Peruvian bark; so called, because the Cardinal Lugo had testimonials of above a thousand cures performed by it in the year 1653.

Cortex cerebri. The cortical substance of the brain. See *Cerebrum.*

Cortex chinæ regius. See *Cinchona.*

Cortex chinæ surinamensis. This bark is remarkably bitter, and preferable to the other species in intermittent fevers.

Cortex chinchinæ. See *Cinchona.*

Cortex elutheriæ. See *Croton cascarilla.*

Cortex geoffroyæ jamaicensis. See *Geoffroya jamaicensis.*

Cortex jamaicensis. See *Achras sapota.*

Cortex lavola. The bark bearing this name is supposed to be the produce of the tree which affords the *Anisum stellatum.* Its virtues are similar.

Cortex magellanicus. See *Winteria aromatica.*

Cortex massoy. The produce of New Guinea, where it is beaten into a pultaceous mass with water, and rubbed upon the abdomen to allay pain of the bowels. It has the smell and flavour of cinnamon.

Cortex patrum. See *Cinchona.*

Cortex peruvianus. See *Cinchona.*

Cortex peruvianus flavus. See *Cinchona.*

Cortex peruvianus ruber. See *Cinchona.*

Cortex pocgerebæ. A bark sent from America; said to be serviceable in diarrhœas, and dysenteries.

Cortex quassiæ. See *Quassia amara.*

Cortex winterianus. See *Winteria aromatica.*

CO'RTICAL. *Corticalis.* 1. Belonging to the bark of a plant or tree.

2. Embracing or surrounding any part like the bark of a tree; as the cortical substance of the brain, kidney, &c.

CORTICO'SUS. Like bark or rind. Applied to the hard pod of the *Cassia fistularis.*

Cortu'sa. See *Sanicula Europæa.*

Co'ru canarica. A quince-like tree of Malabar; it is antidysenteric.

CORUNDUM. A genus of minerals, which, according to Jameson, contains three species; the octohedral, rhomboidal, and prismatic.

CORYDALES. (From κορυς, a helmet.) The name of an order of plants in Linnæus's Fragments of a Natural Method, consisting of plants which have flowers somewhat resembling a helmet or hood.

CO'RYLUS. (Derivation uncertain: according to some, from καρυα, a walnut.) 1. The name of a genus of plants in the Linnæan system. Class, *Monœcia;* Order, *Polyandria.*

2. The pharmacopœial name of the hazel-tree. See *Corylus avellana.*

Corylus avellana. The hazel-nut tree. The nuts of this tree are much eaten in this country; they are hard of digestion, and often pass the bowels very little altered; if, however, they are well chewed, they give out a nutritious oil. An oil is also obtained from the wood of this tree, *Corylus avellana stipulis ovatis, obtusis,* of Linnæus; which is efficacious against the toothache, and is said to kill worms.

CORYMBIFERÆ. (From *corymbus;* a species of florescence, and *fero,* to bear.) Plants which bear corymbal flowers.

CORYMBUS. (Κορυμβον, or κορυμβος, a branch or cluster crowning the summit of a plant; from κορυς, a helmet.) A corymb. That species of inflorescence formed by many flowers, the partial flower-stalks of which are gradually longer, as they stand lower on the common stalk, so that all the flowers are nearly on a level; as in the *Crysanthemum corymbosum.* It is said to be *simple,* when not divided into branches; as in *Thlaspi arvense,* and *Gnaphalium dentatum:* and *compound,* when it has branches; as in *Gnaphalium stæchas.*

Co'ryphe. Κορυφη. The vertex of the head. —*Galen.*

CORY'ZA. (Κορυζα; from καρα, the head, and ζεω, to boil.) An increased discharge of mucus from the nose. See *Catarrh.* Dr. Good makes this a genus of disease; running at the nose. It has two species, *Coryza entonica,* and *atonica.*

Coscu'lia. The grains of kermes.

COSME'TIC. *Cosmeticus.* A term applied to remedies against blotches and freckles.

Co'smos. A regular series. In Hippocrates it is the order and series of critical days.

Co'ssis. A little tubercle in the face, like the head of a worm.

Co'ssum. A malignant ulcer of the nose, mentioned by Paracelsus.

COSTA. A rib. 1. The rib of an animal. See *Ribs.*

2. The thick middle nerve-like chord of a leaf, which proceeds from its base to the apex. See *Leaf.*

Costa herba. The *Hypochæris radicata.*

COSTALIS. (From *costa*, a rib.) Belonging to a rib: applied to muscles, arteries, nerves, &c.

Costa pulmonaria. Very probably the *Hypochæris radicata*, or long-rooted hawkweed, which was used in pulmonary affections, and pains of the side.

COSTA′TUS. Ribbed. Applied to leaves, and is synonymous with *nervous;* the leaf having simple lines extended from the base to the point. See *Leaf.*

Costo-hyoideus. A muscle, so named, from its origin and insertion. See *Omohyoideus.*

CO′STUS. (From *kasta*, Arabian.) The name of a genus of plants in the Linnæan system. Class, *Monandria;* Order, *Monogynia.*

Costus amarus. See *Costus arabicus.*

Costus arabicus. The systematic name of the *Costus indicus; amarus; dulcis; orientalis.* Sweet and bitter costus. The root of this tree possesses bitter and aromatic virtues, and is considered as a good stomachic. Formerly there were two other species, the *bitter* and *sweet*, distinguished for use. At present the Arabic only is known, and that is seldom employed. It is, however, said to be stomachic, diaphoretic, and diuretic.

Costus corticosus. The canella alba.

Costus hortorum minor. The *Achillæa ageratum.*

Costus nigra. The artichoke.

CO′TULE. (Κοτυλη, the name of an old measure.) The socket of the hip-bone. See *Acetabulum.*

Cotaro′nium. A word coined by Paracelsus, implying a liquor into which all bodies, and even their elements, may be dissolved.

Co′tis. (From κοττη, the head.) The back part of the head; sometimes the hollow of the neck.

CO′TULA. (*Cotula*, diminutive of *cos*, a whetstone, from the resemblance of its leaves to a whetstone; or from κοτυλη, a hollow.) Stinking chamomile.

Cotula fœtida. See *Anthemis cotula.*

COTYLEDON. (*Cotyledon, onis.* f.; from κοτυλη, a cavity.) Seed-lobe, or cotyledon. The *cotyledones* are the two halves of a seed, which, when germinating, become two pulpy leaves, called the *seminal leaves.* These leaves are often of a different *form* from those which are about to appear; as in the *Raphanus sativus;* and sometimes they are of another *colour;* as in *Cannabis sativa*, the seminal leaves of which are white.

Almost all the cotyledons wither and fall off, as the plant grows up.

These bodies are spoken of in the plural, because it is much doubted whether any plant can be said to have a solitary cotyledon, so that most plants are *dicotyledonous.* Plants without any, are called *acotyledones.* Those with more than two, *polycotyledonous.*

Between the two cotyledons of a germinating seed, is seated the *embryo*, or germ of the plant, called by Linnæus, *corculum*, or little heart, in allusion to the heart of the walnut. Mr. Knight denominates it the germen: but that term is appropriated to a very different part, the rudiment of the fruit. The expanding embryo, resembling a little feather, has, for that reason, been called by Linnæus, *plumula:* it soon becomes a tuft of young leaves, with which the young stem ascends. See *Corculum.*

COTYLOID. (*Cotyloides;* from κοτυλη, the name of an old measure, and ειδος, resemblance.) Resembling the old measure, or *cotule.*

Cotyloid cavity. The acetabulum. See *Innominatum os.*

COTYLOI′DES. See *Cotyloid.*

COUCHING. A surgical operation that consists in removing the opaque lens out of the axis of vision, by means of a needle constructed for the purpose.

Couch-grass. See *Triticum repens.*

COUGH. *Tussis.* A sonorous concussion of the thorax, produced by the sudden expulsion of the air from the chest through the fauces. See *Catarrh.*

Co′um. The meadow-saffron.

COUNTER-OPENING. *Contra-apertura.* An opening made in any part of an abscess opposite to one already in it. This is often done in order to afford a readier egress to the collected pus.

Coup de soleil. The French for an erysipelas or apoplexy, or any affection produced instantaneously from a scorching sun.

Cou′rap. (Indian.) The provincial name of a disease of the skin common in Java, and other parts of the East Indies, accompanied by a perpetual itching and discharge of matter.

Cou′rbaril. The tree which produces the gum anime. See *Anime.*

Couro′ndi. An evergreen tree of India, said to be antidysenteric.

Couroy moelli. A shrub of India, said to be antivenomous.

Cou′scous. An African food, much used about the river Senegal. It is a composition of the flour of millet, with some flesh, and what is there called lalo.

Covola′m. See *Cratæva marmelos.*

COWHAGE. See *Dolichos pruriens.*

COW-ITCH. See *Dolichos pruriens.*

COWPER, William, was born about the middle of the 17th century, and became distinguished as a surgeon and anatomist in this metropolis. His first work, entitled "Myotomia Reformata," in 1694, far excelled any which preceded it on that subject in correctness, though since surpassed by Albinus. Three years after, he published at Oxford "the Anatomy of Human Bodies," with splendid plates, chiefly from Bidloo; but forty of the figures were from drawings made by himself; he added also some ingenious and useful anatomical and surgical observations. Having been accused of plagiarism by Bidloo, he wrote an apology, called "Eucharistia;" preceded by a description of some glands, near the neck of the bladder, which have been called by his name. He was also author of several communications to the Royal Society, and some observations inserted in the anthropologia of Drake. He died in 1710.

Cowper's glands. (*Cowperi glandulæ;* named from Cowper, who first described them.) Three large muciparous glands of the male, two of which are situated before the prostate gland under the accelerator muscles of the urine, and the third more forward, before the bulb of the urethra. They excrete a fluid, similar to that of the prostate gland, during the venereal orgasm.

Cowpe′ri glandulæ. See *Cowper's glands.*

CO′XA. The ischium is sometimes so called, and sometimes the os coccygis.

COXE′NDIX. (From *coxa*, the hip.) The ischium; the hip-joint.

Crablouse. A species of pediculus which infests the axillæ and pudenda.

Crab-yaws. A name in Jamaica for a kind of ulcer on the soles of the feet, with callous lips, so hard that it is difficult to cut them.

CRA'MBE. (Κραμβη, the name given by Dioscorides, Galen, and others, to the cabbage; the derivation is uncertain.) The name of a genus of plants in the Linnæan system. Class, *Tetradynamia;* Order, *Siliculosa.* Cabbage.

Crambe maritima. The systematic name for the sea-cole, or sea-kale. A delicious vegetable when forced and blanched. It is brought to table about Christmas, has a delicate flavour, and is much esteemed. Like to all oleraceous plants, it is flatulent and watery.
